

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

A MANUAL
OF
MEDICAL JURISPRUDENCE.

BY

ALFRED SWAINE TAYLOR, M.D., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS;
HONORARY MEMBER OF THE MEDICO-LEGAL SOCIETY OF NEW YORK, OF THE SOCIÉTÉ DE
MÉDECINE LÉGALE OF PARIS, AND OF THE MEDICAL SOCIETY OF SWEDEN;
LATE LECTURER ON MEDICAL JURISPRUDENCE AND CHEMISTRY IN GUY'S HOSPITAL.

Quod nonne exemplis tuemur mox inter exempla erit.

EIGHTH AMERICAN EDITION,

FROM THE

TENTH LONDON EDITION, CONTAINING THE AUTHOR'S LATEST NOTES MADE
EXPRESSLY FOR THIS EDITION: EDITED, WITH ADDITIONAL
NOTES AND REFERENCES,

BY

JOHN J. REESE, M.D.,

PROFESSOR OF MEDICAL JURISPRUDENCE AND TOXICOLOGY IN THE UNIVERSITY OF PENNSYLVANIA,
FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA, PHYSICIAN TO ST. JOSEPH'S
HOSPITAL AND TO THE GIRARD COLLEGE FOR ORPHANS, HONORARY MEMBER
OF THE NEW YORK MEDICO-LEGAL SOCIETY.

WITH ILLUSTRATIONS ON WOOD.

COLLINS, PRINTER.

PREFACE TO THE EIGHTH AMERICAN EDITION.

THE editor of the present American issue of Dr. Taylor's well-known work on Medical Jurisprudence takes occasion to express his deep sense of the loss sustained by the professions of both law and medicine in the recent death of its lamented author.

This revision, undertaken expressly for the benefit of his American brethren, proved his last work ; almost immediately after its completion was he summoned from the sphere of his earthly labors.

Dr. Taylor's additions, scattered throughout the volume, will be found quite numerous, serving to place this record of the progress of the science of Medical Jurisprudence thoroughly on a level with the latest experience and research. The editor may therefore congratulate the medico-legal student that he has had the good fortune to secure these valuable additions from the now departed master.

As was the case in the last American issue, the editor has deemed it wise to enlarge occasionally upon certain subjects, with materials selected from the author's larger work, "The Principles and Practice of Medical Jurisprudence," a book to which every reader may not have ready access.

The valuable notes of the former editors, Dr. Hartshorne and Judge Penrose, have, for the most part, been retained. They will be found inclosed in brackets, and distinguished by letters (H) and (P). Those of the present editor are designated by the letter (R).

The hope is therefore expressed that the volume may be found worthy a continuance of the favor which has carried it to an eighth edition, and has caused it to be regarded as a standard authority on all the subjects embraced within its scope.

PHILADELPHIA, November, 1880.

PREFACE TO THE TENTH LONDON EDITION.

THE tenth edition of a work requires but a short introductory notice. The many thousand copies that have been circulated since the first appearance of this Manual, in 1844, have rendered it well known to members of the legal and medical professions. It is not, therefore, necessary on this occasion to say more than that no efforts have been spared to render the new edition a useful guide to students and practitioners in law and medicine. The work has been revised throughout, and notices of those cases of interest which have occurred since the former edition, have been introduced into the appropriate chapters. For some of these, as well as for many useful suggestions on medico-legal subjects, I am indebted to known as well as unknown correspondents. I here beg leave to thank them for their kind contributions, and for the assistance thus rendered to me in completing this edition.

CONTENTS.

MEDICAL EVIDENCE.

CHAPTER I.

	PAGE
The practice of Medical Jurisprudence—Medical and medico-legal duties—Inspection of bodies in death from wounds or poisoning—Use of notes—Medico-legal reports—Dying declarations	17

CHAPTER II.

Coroners' inquests—Trial at the assizes—Subpoenas—Medical fees—Examination in chief—Duties of medical witnesses—Quotations from books—Presence in court—License of counsel—Rules for the delivery of evidence	36
---	----

CHAPTER III.

Causes of death—Sudden death—Syncope, asphyxia, coma—Signs or indications of death—Cessation of circulation and respiration—Cooling of the body—Cadaveric rigidity—Putrefaction—Changes produced in the body—Putrefaction mistaken for gangrene—Cadaveric lividity—Adipocere	58
--	----

POISONING.

CHAPTER IV.

Definition of the term poison—Deadly poisons—Mechanical irritants—Law in relation to the administering of poisons—Influence of habit and idiosyncrasy—Classification—Special characters of irritant, corrosive, and neurotic poisons	78
--	----

CHAPTER V.

Evidence of poisoning in the living body—Action of poisons increased or diminished by disease—Symptoms connected with food or medicine—Several persons attacked simultaneously—Evidence from the detection of poison in the food, etc.	88
--	----

CHAPTER VI.

	PAGE
Evidence of poisoning in the dead body—Period at which poisons prove fatal—Chronic poisoning—Appearances produced by the different classes of poisons—Redness of the mucous membrane mistaken for inflammation—Ulceration and corrosion—Softening—Perforation of the stomach from poison and disease	96

CHAPTER VII.

IRRITANT POISONS :—Sulphuric acid, or Oil of vitriol—Nitric acid, or Aqua fortis—Hydrochloric acid—Symptoms—Appearances and analysis	106
--	-----

CHAPTER VIII.

Poisoning by Oxalic acid—Symptoms and appearances—Chemical analysis—Acid oxalate of potash, or Salt of sorrel—Tartaric and Acetic acids	116
---	-----

CHAPTER IX.

Poisoning by Alkalies and Alkaline salts—Potash, soda, and ammonia—Nitrate and Sulphate of potash—Chloride of barium	122
--	-----

CHAPTER X.

Phosphorus—Symptoms and appearances—Chronic poisoning—Chemical analysis—Red or allotropic phosphorus	129
--	-----

CHAPTER XI.

METALLIC IRRITANTS :—Arsenic—Arsenious acid—Symptoms—Chronic poisoning—Appearances after death—Fatal dose—Chemical analysis—Arsenites—Arsenic acid—Orpiment and other compounds	136
---	-----

CHAPTER XII.

Poisoning by Mercury—Corrosive sublimate—Symptoms—Chronic poisoning—Appearances after death—Chemical analysis—Process for mercury in organic liquids—Calomel—White and red precipitates—Other compounds of mercury	156
--	-----

CHAPTER XIII.

On poisoning with Lead—Sugar of lead—Symptoms—Appearances after death—Chemical analysis—Lead in organic mixtures—Carbonate or white lead—Chronic poisoning—Poisoning with Copper—Blue vitriol—Symptoms—Appearances—Chemical analysis—Copper in organic liquids	165
--	-----

CHAPTER XIV.

	PAGE
Tartar emetic—Symptoms—Appearances—Chronic poisoning—Chemical analysis—Chloride or butter of antimony—Poisoning with salts of Zinc and Iron	174

CHAPTER XV.

VEGETABLE AND ANIMAL IRRITANTS:—Vegetable irritants—Aloes—Savin—Croton oil—Colchicum—Hellebore—Animal irritants—Cantharides—Noxious animal food—Fish—Mussels—Cheese—Sausages—Poisoned flesh of animals—Trichiniasis	183
---	-----

CHAPTER XVI.

NEUROTIC POISONS:—Opium—Symptoms—Appearances—Its action on infants—Poisoning with opiate compounds—Morphia and its salts—Process for detecting opium in organic mixtures	200
--	-----

CHAPTER XVII.

Prussic acid—Symptoms and appearances—Tests for the acid—Process for organic mixtures—Cyanide of potassium—Essential oil of bitter almonds—Nitrobenzole	207
---	-----

CHAPTER XVIII.

Alcohol—Ether—Chloroform—Hydrate of chloral—Camphor—Cocculus indicus—Picrotoxine—Fungi—Henbane	216
--	-----

CHAPTER XIX.

Nux vomica—Strychnia—Symptoms and appearances—Chemical and microscopical analysis of nux vomica and strychnia—Process for organic mixtures—Brucia	229
---	-----

CHAPTER XX.

Conium maculatum—Hemlock—Conia—Ceanothe crocata—Æthusa cynapium—Aconite or monkshood—Aconitina	237
--	-----

CHAPTER XXI.

Atropa belladonna, or Deadly nightshade—Poisoning by Atropia—Lobelia—Datura stramonium, or Thornapple—Daturia	246
---	-----

CHAPTER XXII.

Tobacco—Nicotina—Foxglove, or Digitalis—Digitaline—Other poisonous substances	253
---	-----

WOUNDS AND PERSONAL INJURIES.

CHAPTER XXIII.

	PAGE
Definition of a wound—Danger to life—Grievous bodily harm—Examination of wounds—Description of wounds—Characters of wounds inflicted on the living and dead body—Ecchymosis in the living and dead—Effects of violence on the dead body—Ecchymosis not always a result of violence	257

CHAPTER XXIV.

Evidence of the use of a weapon—Characters of wounds caused by weapons—Incised, punctured, lacerated, and contused wounds—Stabs and cuts—What are weapons?—Examination of the dress—Imputed or self-inflicted wounds	265
--	-----

CHAPTER XXV.

Wounds indicative of homicide, suicide, or accident—Evidence from the situation of a wound—Evidence from nature and extent—Evidence from the direction of a wound—Wounds inflicted by the right or left hand—Several wounds—Use of several weapons	276
--	-----

CHAPTER XXVI.

Evidence from circumstances—The position of the body—Of the weapon—Evidence from blood, hair, and other substances on weapons—Marks of blood on clothing and furniture, on the deceased, and on the assailant	284
---	-----

CHAPTER XXVII.

Chemical examination of blood-stains—Stains of blood on linen and other stuffs—Age or date of the stains—other stains resembling blood—Blood on weapons—Arterial and venous blood—Varieties of blood—Blood of man and animals—Microscopical evidence	295
--	-----

CHAPTER XXVIII.

The cause of death from wounds—Wounds directly or indirectly fatal—Death from hemorrhage—Internal bleeding—Death from mechanical injury—From shock—Death from numerous personal injuries irrespective of any mortal wound	313
---	-----

CHAPTER XXIX.

Death of wounded persons from natural causes—Distinction between real and apparent cause—Death from wounds or latent disease—Accelerating cause—Death from wounds after long periods—Avoidable causes of death—Neglect—Imprudence—Unskilful treatment—Unhealthy state of body	320
---	-----

CHAPTER XXX.

	PAGE
Wounds indirectly fatal—Tetanus following wounds—Erysipelas—Delirium tremens—Gangrene—Death from surgical operations—Primary and secondary causes of death—Unskilfulness in operations—Pyæmia—Medical responsibility in reference to operations—Actions for malapraxis	332

CHAPTER XXXI.

Cicatrization of wounds—Evidence from cicatrices—Changes in an incised wound—Is a cicatrix always a consequence of a wound?—Are cicatrices when once formed indelible?—Characters of cicatrices—Their age or date—Cicatrices from bleeding, cupping, setons, and issues—Cicatrices from disease distinguished from those of wounds	341
--	-----

CHAPTER XXXII.

Medical evidence of identity from colored cicatrices or tattoo-marks—Mode and date of production—Durability of these marks—Their alleged spontaneous disappearance—Cases of identity from tattooing—Simulated marks—Tattoo-marks on the dead—Medical responsibility	352
---	-----

CHAPTER XXXIII.

Wounds of the head—Concussion—How distinguished from intoxication—Effusion of blood as a result of violence, disease, or mental excitement—Wounds of the face—Deformity as a consequence of wounds of the face—Injuries to the spine and spinal marrow—Fractures of the vertebræ	361
--	-----

CHAPTER XXXIV.

Wounds of the chest—Wounds and ruptures of the lungs and heart—Wounds of large bloodvessels—Wounds and ruptures of the diaphragm—Direction of wounds of the chest—Wounds of the abdomen—Death from blows on the cavity—Ruptures of the liver, gall-bladder, spleen, kidneys, intestines, stomach, and urinary bladder—Wounds of the genital organs	374
--	-----

CHAPTER XXXV.

Fractures—Produced by a blow with a weapon or by a fall—Brittleness of the bones—Fractures caused by slight muscular exertion—Fractures in the living and dead body—Has a bone ever been fractured?—Locomotion—Dislocation from violence or natural causes—Medical opinion—Actions from malapraxis	391
--	-----

CHAPTER XXXVI.

Gunshot wounds—In the living and dead body—Was the piece fired near or from a distance?—Accidental, suicidal, or homicidal wounds—Position of the wounded person when shot—Wounds from small shot—Wounds from wadding and gunpowder	396
---	-----

CHAPTER XXXVII.

PAGE

Death from burns and scalds—Symptoms—Stupor—Cause of death—Post-mortem appearances—Burns in the dead body—Accident, homicide, or suicide—Wounds caused by fire—Scalding—Burns by corrosive liquids	406
--	-----

 ASPHYXIA.

CHAPTER XXXVIII.

DROWNING :—Cause of death—Secondary causes—Post-mortem appearances—Medical proofs of death from drowning—Specific gravity of the body—Coincidental causes of death—Marks of violence—Accidental fractures—Homicidal and suicidal drowning	415
---	-----

CHAPTER XXXIX.

HANGING :—Cause of death—Death from the secondary effects—Post-mortem appearances—Mark of the cord or ligature—Was death caused by hanging?—Hanging after death—Summary of medical evidence—Marks of violence on the hanged—Was the hanging the result of accident, suicide, or homicide?—The position of the body	436
--	-----

CHAPTER XL.

STRANGULATION :—Cause of death—Appearances after death—Was death caused by strangulation, or was the constriction applied to the neck after death?—Marks of violence—Accidental, homicidal, and suicidal strangulation	455
--	-----

CHAPTER XLI.

SUFFOCATION :—Suffocation from mechanical causes—Cause of death—Appearances after death—Evidence of death from suffocation—Accidental, suicidal, and homicidal suffocation—Smothering	472
---	-----

CHAPTER XLII.

GASEOUS POISONS :—Carbonic acid—Symptoms—Appearances—Analysis—Effects of charcoal-vapor—Carbonic oxide—Coal and coke vapor—Sulphurous acid—Vapors of lime, cement, and brick kilns—Confined air—Coal-gas—Carburetted hydrogen—Nitrous oxide—Sulphuretted hydrogen—Effluvia of drains and sewers—Exhalations from the dead	488
---	-----

CHAPTER XLIII.

PAGE

LIGHTNING, COLD, HEAT, STARVATION:—Effects of the electric fluid—Post-mortem appearances—Cold an occasional cause of death—Symptoms—Circumstances which accelerate death—Post-mortem appearances—Effect of heat—Starvation a rare cause of death—Symptoms—Appearances after death—Legal relations	518
--	------------

PREGNANCY.

CHAPTER XLIV.

Signs of pregnancy—Suppression of the menses—Quickening—Sounds of the fetal heart—Feigned pregnancy—Concealed pregnancy—Pregnancy in the dead—Impregnation in a state of unconsciousness—Legal relations	540
---	------------

CHAPTER XLV.

DELIVERY:—Delivery in the living—Concealed delivery—Signs of abortion in the early stages of pregnancy—Signs of recent and remote delivery—Feigned delivery—Delivery in a state of unconsciousness—Signs of delivery in the dead—True and false corpora lutea—Characters of the ovum or embryo—Moles—Concealment of birth	558
--	------------

CHAPTER XLVI.

CRIMINAL ABORTION:—Abortion from natural causes—Criminal causes—Mechanical means—Medicinal substances—Signs of abortion—Specific abortives—Local applications—Feigned abortion—Meaning of the word “noxious” as applied to drugs—On inducing premature labor—Proof of pregnancy not necessary—Abortion of monsters—Moles and hydatids	572
--	------------

INFANTICIDE.

CHAPTER XLVII.

Nature of the crime—Medical evidence at inquests—Uterine age or maturity of the child—Characters of the child from the sixth to the ninth month—Signs of maturity—Rules for inspecting the body	594
--	------------

CHAPTER XLVIII.

Evidence of life before respiration—Putrefaction in utero—Evidence of life after respiration—Color, volume, consistency, and absolute weight of the lungs—Static test—Weight increased by respiration	600
--	------------

CHAPTER XLIX.

PAGE

The hydrostatic test—Sinking of the lungs from disease or atelectasis—Life with perfect atelectasis or entire absence of air from the lungs—Erroneous medical inference from sinking of the lungs—Floating of the lungs from putrefaction—Effects of putrefaction on the lungs 608

CHAPTER L.

Floating of the lungs from artificial inflation—Inflation not distinguishable from imperfect respiration—Results of compression—Improper objections to the hydrostatic test—Respiration before birth—Respiration a sign of life, not of live birth—General conclusion 615

CHAPTER LI.

On the proofs of a child having been born alive—Evidence from respiration—From marks of violence—From natural changes in the foetal vessels—From the discovery of food in the stomach—General conclusions 622

CHAPTER LII.

Causes of death in new-born children—Proportion of children born dead—Natural causes of death—A protracted delivery—Debility—Bleeding from laceration of the navel-string—Compression of the navel-string—Malformation—Destruction of monstrous births—Death from congenital disease 633

CHAPTER LIII.

Violent causes of death—Suffocation—Drowning—Death of the child from cold and exposure—Starvation—Death from immaturity—Wounds in new-born children—Fractures of the skull, accidental and criminal—Twisting of the neck—Violence in self-delivery—Power of locomotion and exertion in females after delivery 639

CHAPTER LIV.

Death of the child from strangulation—Strangulation by the navel-string—Accidental marks resembling those of strangulation—Constriction before and after death—Before and after breathing—Before and after the severance of the navel-string—Examination of women—Medical responsibility 653

BIRTH, INHERITANCE.

CHAPTER LV.

LIVE BIRTH IN CIVIL CASES—Date of birth—Signs of live birth independently of respiration or crying—Vagitus uterinus—Tenancy by courtesy—Legal birth—Post-mortem births—Minority and majority—Plural and monstrous births 664

CHAPTER LVI.

LEGITIMACY:—Presumption of legitimacy—Natural period of gestation—Duration of pregnancy from one intercourse—Premature births—Short periods of gestation—Viability—Earliest period at which a child may be born living—Evidence from the state of the child—Protracted births—The period of gestation not fixed by law 681

CHAPTER LVII.

PATERNITY:—Disputed paternity—Parental likeness—Affiliation—Posthumous children—Superfoetation in relation to legitimacy—Supposititious children—Sexual malformations 701

IMPOTENCY, STERILITY.

CHAPTER LVIII.

IMPOTENCY:—Causes—Procreative power in the male—Puberty—Age for virility—Virility of cryptorchides and monorchides—Sterility—Procreative power in the female—Earliest and latest periods for child-bearing—Legal relations 721

RAPE.

CHAPTER LIX.

SOURCES OF MEDICAL EVIDENCE—Rape on infants and children—Marks of violence—Purulent discharges from the vagina—Evidence from gonorrhœa and syphilis—Rape on girls after puberty—Defloration—Signs of virginity . 743

CHAPTER LX.

RAPE ON MARRIED AND ADULT WOMEN—Circumstances under which it may be perpetrated on adult women—Loss of physical evidence—Pregnancy following rape—Microscopical evidence—Sodomy 760

INSANITY.

CHAPTER LXI.

	PAGE
What is insanity?—Medical definitions—Distinction of sane from insane persons—Moral insanity—Legal definitions—"Non compos mentis"—Symptoms of incipient insanity—Hallucinations and illusions—Lucid intervals	777

CHAPTER LXII.

Varieties of insanity—Mania—Abstinence from food—Delusions regarding poison—Delirium distinguished from mania—Monomania—Dementia—Idiocy—Imbecility—Hereditary transmission—Feigned insanity—Appearances after death—Eccentricity	785
--	-----

CHAPTER LXIII.

Medico-legal questions in relation to the insane—Application of restraint—Illegal imposition of restraint—Violence of temper—Certificates of insanity—Rules for the discharge of lunatics	796
---	-----

CHAPTER LXIV.

Lunatics as witnesses—Interdiction—Commissions of lunacy—Examination of alleged lunatics—Medical and legal tests of competency—Conflict of evidence and opinion	809
---	-----

CHAPTER LXV.

Civil responsibility—Testamentary capacity—Wills made by the insane—Test of capacity—Evidence of delusion—Eccentricity in wills	820
---	-----

CHAPTER LXVI.

The plea or defence of insanity—Circumstances under which it is admissible—Homicidal insanity—Moral insanity—Symptoms—Legal tests—Medical tests—Delusion—Tests of irresponsibility—Medical evidence	831
---	-----

CHAPTER LXVII.

Suicidal mania—Suicide not necessarily an indication of insanity—Suicide a felony—In relation to life insurance—Puerperal mania—Pyromania—Kleptomania—Erotomania—Dipsomania—Responsibility of drunkards—Delirium tremens—Somnambulism—The deaf and dumb	850
---	-----

LIFE INSURANCE.

CHAPTER LXVIII.

	PAGE
Principles of Life Insurance—What diseases have and what diseases have not a tendency to shorten life?—Legal decisions respecting the meaning of these words—Concealment of diseases—What is material concealment?—Concealment of habits—What is intemperance?—Proximate and remote effects—Delirium tremens—Epilepsy—Phthisis—Abstinence—Vegetarianism—Opium eating—Inveterate smoking—Insanity—Voidance of policies by suicide—Secret poisoning of persons whose lives are insured	872

MEDICAL JURISPRUDENCE.

MEDICAL EVIDENCE.

CHAPTER I.

THE PRACTICE OF MEDICAL JURISPRUDENCE.—MEDICAL AND MEDICO-LEGAL DUTIES.—INSPECTION OF BODIES IN DEATH FROM WOUNDS OR POISONING.—USE OF NOTES.—MEDICO-LEGAL REPORTS.—DYING DECLARATIONS.

MEDICAL JURISPRUDENCE—or, as it is sometimes called, **FORENSIC, LEGAL, or STATE MEDICINE**—may be defined to be that science which teaches the application of every branch of medical knowledge to the purposes of the law ; hence its limits are, on the one hand, the requirements of the law, and on the other, the whole range of medicine. Anatomy, physiology, medicine, surgery, chemistry, physics, and botany lend their aid as necessity arises ; and in some cases all these branches of science are required to enable a court of law to arrive at a proper conclusion on a contested question affecting life or property.

The purpose of this work is to bring, as far as possible, within a limited compass, those subjects which especially demand inquiry, and which more particularly concern the duties of the educated physician and surgeon. The definition above given necessarily implies that a medical jurist should have a theoretical and practical knowledge of all branches of the profession, a large range of experience, and the rare power of adapting his knowledge and experience to emergencies. He should be able to elucidate any difficult medico-legal question which may arise, and be prepared at all times to make a cautious selection of such medical facts, and a proper application of such medical principles, as may be necessary to enable a judge to place the subject in an intelligible light before a jury, and to enable a jury to arrive at a just conclusion.

The variety of subjects of which a medical jurist is required to have knowledge may well alarm a student, and lead him to suppose that, as he cannot make himself perfectly acquainted with all, he may well forego the labor of preparing himself in any. But this would be taking an erroneous view of his position. This description of the qualifications necessary to constitute a normal witness in a court of law must not deter him from entering on the study. It is assuredly beyond the mental

power of any individual that he should be at the same time profoundly versed in all the principles of medicine and jurisprudence, and that he should be able to answer all possible questions, and encounter and remove *all* medical difficulties that may occur during the trial of a civil or criminal case. All that the law expects from a medical man is a fair average knowledge, not merely of his profession, but of that which falls more peculiarly under the province of a medical witness. There can be no doubt that the more perfectly a man has made himself master of his profession, the better will he be fitted to follow the principles and apply himself to the practice of medical jurisprudence; but he must divest himself of the notion that these principles can be spontaneously acquired, or that they are necessarily derived from the study of those isolated branches of medicine upon which medical jurisprudence is based. The materials for the medical jurist undoubtedly exist in these collateral sciences; but they require to be assorted, selected, and moulded into shape, before they can be applied to any useful or practical purpose.

The duties of a medical jurist are distinct from those of a physician or surgeon; the latter looks only to the treatment of disease or accident and the saving of life; but the object of the former, in a large proportion of cases, is, whether in reference to the living or dead, to aid the law in fixing on the perpetrator of a crime, or to rescue an innocent person from a falsely imputed crime. Thus he may be required to determine whether, in a particular case, the cause of death is natural or violent; and for this purpose it will be necessary for him to make an entirely new application of his professional knowledge. He has now the difficult task of making a selection from those parts of the medical sciences which bear upon the legal proof and development of crime.

Some members of the profession have been inclined to look upon medico-legal practice as an unnecessary addition to their ordinary duties; but there are few who have been long engaged in practice, who have not found themselves occasionally placed in situations of difficulty from the accidental occurrence of cases demanding medico-legal investigation. A medical man is summoned to attend a person laboring under the effects of poison criminally administered, but at the time he may have no knowledge or even suspicion that poison is the cause of the symptoms. In spite of the best treatment, death ensues; here the functions of the medical man end, and those of a medical witness begin. It is utterly impossible that he can now avoid giving evidence, or shift the responsibility on another; the law will insist upon his appearance, first in the court of the coroner, and afterwards at the Assizes. It will here be assumed that as a registered member of the profession he is fully competent to answer every question put to him by judge and counsel relative to the general effects of poisons, the quantity required to destroy life, and the time within which a poison may prove fatal. It may be objected to his evidence, that the deceased had died from the effects of disease, and not from poison; in which case the cross-examination will lead to a searching inquiry into all those diseases which resemble poisoning in their symptoms and post-mortem appearances as well as the means of making a certain distinction between them; and the fallacies to which the chemical processes for the detection of poison are liable.

On another occasion, a medical man may be called to render assistance to one who has been stabbed in a quarrel, and who speedily dies from the wound. The office of the surgeon here ceases, while that of the medical jurist commences. He must now be prepared to answer numerous questions, all bearing upon the legal proof of crime, all necessary in law, although apparently superfluous in surgery. Thus he may be asked to state the precise characters of a wound inflicted upon the body of a man soon after death; and by what means a particular wound was inflicted? Was it homicidal, or accidental? The amount of blood lost? Whether the person could have moved, or performed any act after receiving it? Are certain red spots found upon his clothes, or upon a knife belonging to him, owing to effused blood or other causes? Whether any, and what statements were made by the dying man, and what were the precise circumstances under which they were made? It need hardly be observed that questions of this nature are rarely noticed, except in a cursory manner, by professors of chemistry and surgery, and a medical man is not likely to acquire the means of answering them by intuition. On the other hand, regarding ourselves as living in a civilized state, in which the detection and punishment of crimes against life and property are indispensable to the security of all, it is impossible to overrate their importance. Unless a witness is able to return answers to these questions when a public necessity occurs, a guilty man may escape punishment, while an innocent man may be condemned. He may thus most seriously injure his own reputation, for it is certain that his qualifications as a physician, surgeon, or general practitioner, however great, will not shield him from general reprobation.

Thus, then, it is obvious that the duties of a medical jurist are of a highly responsible nature and of great importance to society, while the cases which call them into exercise are of purely accidental occurrence. A medical practitioner who thinks himself secure in the most retired corner of the kingdom, is liable to find himself suddenly summoned as a witness on a trial, to answer questions which perhaps during a long period of practice he had been led to regard as unimportant. Under the circumstances it is scarcely possible that he can avoid exposing his deficiencies, and the final question will be, *Have you ever attended to, or thought of, these subjects before?* A negative answer to this question, while it commonly brings with it public censure, will in most instances lead to the acquittal of the accused, in spite of strong presumptions of guilt.

I have endeavored to avoid overdrawing this picture; its truth will, I am sure, be felt and acknowledged by those who have been a few years engaged in practice. The records of courts of law contain many unfortunate exposures, which might have been easily avoided, had the witnesses only availed themselves of the opportunities afforded to them while students, of acquiring a knowledge of the subject; but they had unreflectingly acted on the principle that medical jurisprudence was a dry, dull, and useless study, and that the practice of it was remote and speculative. This feeling is, however, fast disappearing. Those who have been compelled by circumstances to give their attention to it, have in subsequent cases taken care to prepare themselves for the ordeal through which every medical witness must pass.

Some medical men who have treated legal medicine with indifference have occasionally ventured to act as witnesses, thinking that the subjects on which they were likely to be examined were so little known to judge and counsel, that even hazardous or rash statements would escape observation; such witnesses, however, have often found to their cost that they were laboring under a fatal delusion. Various circumstances have led, in recent times, to the acquisition of much medico-legal knowledge by lawyers, especially in relation to questions connected with wounds, child-murder, and poisoning, and they are not slow in detecting and exposing a mere pretender who attempts to shelter himself by vague or evasive statements and technical language. Another fact must be borne in mind: there are few counsel engaged in any civil or criminal case of importance, who do not take care to fortify themselves under medical advice; with a full knowledge of the views of standard medical writers on the subject in dispute; and with these works before them, and with their proverbial acuteness, he must, indeed, be a clever witness who can succeed in passing off an erroneous or evasive answer to a medico-legal question.

It is a frequent charge against members of the medical profession that they are the worst witnesses on matters of fact and opinion. I believe this to be an unmerited censure. Those who are ready to make this charge overlook the number, complexity, and difficulty of the questions which are put to medical men compared with those put to other witnesses. They also forget that medical men are much more frequently summoned as witnesses than the members of the two other learned professions. Their evidence obtains much greater publicity, and is necessarily exposed to a wider circle of criticism. The fact is, that good and bad witnesses are to be met with in every profession, and under equal conditions there is no reason to suppose that one would furnish a greater number of incompetent witnesses than another. It is certainly the fault of medical men that they are not generally prepared for the questions which are likely to arise in a case on which they know they will be required to give evidence. This want of preparation frequently applies to facts as well as to opinions. Thus, in reference to a case on which a charge of murder or manslaughter may be ultimately founded, a medical man who is called in omits to observe many circumstances, because at the time they appear to him to have little importance, although at the subsequent trial he may find, to his dismay, that they actually become the turning points of innocence or guilt. Medical observation as a result of professional habits is, on these occasions, in general confined to only one set of circumstances—the recognition and treatment of accident or disease; but medico-legal observation should take a much wider range than this, and should be directed to all the surrounding facts and incidents of a case. The essential difference in the two kinds of practice is, that circumstances which are of no interest in a medical or surgical point of view, are often of the greatest value and importance in legal medicine. It is obvious, that, if they are not observed by a medical witness when he is first summoned to the injured person, whether dying or dead, it will be out of his power to meet many of the questions which must arise in the progress of the case. The non-observance of these

facts is a serious evil, and often carries with it, although unjustly, an imputation of professional ignorance.

The first duty, therefore, of a medical jurist is to cultivate a faculty of minute observation of medical and moral circumstances. This, when combined with a general knowledge of what the law requires as evidence, will enable him to meet in a satisfactory manner all the scientific questions that may be necessary for the elucidation of a case. The exercise of this faculty is by no means inconsistent with the performance of his duties as a surgeon. A learned judge on one occasion remarked that "*a medical man, when he sees a dead body, should notice everything.*" Undoubtedly he should observe everything which could throw a light upon the production of wounds or other injuries found upon it. It should not be left to policemen to say whether there were any marks of blood on the dress or on the hands of the deceased, or on the furniture in the room. The dress of the deceased as well as the body should be always closely examined on the spot by the medical man. The importance of this precaution is well illustrated by a certain case in which a man just escaped committal on what would have proved a false charge of murder, by reason of the examination of an article of dress accidentally produced at the adjourned inquest.

There is another point which is frequently omitted on these occasions, and the omission may give rise to great inconvenience, if not to a failure of justice. Thus, in reference to a dead body, no observation is made at the time of the visit whether it or any part of it is cold or warm; whether the limbs are cold and rigid, or cold and pliant. In a medical and surgical view these conditions of the body are of no importance whatever, but medico-legally, if the facts are observed, they may enable a witness to speak with greater or less probability on *the time of death*: this may make all the difference between the acquittal and conviction of a person charged with murder. The case of *Gardner*, elsewhere related, will show the importance of observations of this kind.

It may stimulate the attention of a medical practitioner in reference to these inquiries if he is informed that the great art of counsel, who defend persons charged with murder or manslaughter, consists in endeavoring to discover *what he omitted to do*. Although sometimes the omission may be really of no medical importance whatever, yet it is usually placed before the jury in such a strong light that the accused obtains the benefit of a doubt. The omission may be attributed to professional ignorance, or, what is worse, to professional bias—a determination to find proofs of guilt against the "unhappy prisoner at the bar"—when the facts might be innocently explained by a want of experience on the part of the witness in dealing with cases of this nature.

If we except medical experts, who are selected according to their experience in different branches of the profession, medical men have no option respecting medico-legal practice; for the cases which give rise to medico-legal questions are always more or less connected with the practice of medicine and surgery. Thus before any inquiry is instituted by a magistrate or coroner, and before any suspicious circumstances have come to light, a medical man may be summoned to a person dying from the effects of a wound, or from the secret administration of poison. The

dying person may make to him a declaration or statement as to the circumstances under which the wound was inflicted or the poison administered ; he may also mention the names of the person or persons concerned in the assault or the administration. This *dying declaration* or statement, according to the circumstances under which it is made, may become of material importance in the prosecution of a party charged with murder or manslaughter. It is therefore proper that a practitioner should observe and make notes of the *exact condition* of the patient ; whether, when he makes the statement, he is under the conviction or belief that he is about to die. It has been thought that it was also necessary to prove that the wounded man had lost all hope of recovery ; but, as a learned judge has justly remarked, it is very difficult, if not impossible, to say on these occasions, when, if ever, the feeling of hope completely deserts a man. Again, a man may express an opinion that he shall "not recover," but this is not sufficient. The law admits these declarations not because recovery is impossible, but because the person making the statement has in his mind at the time of making it a full conviction of approaching death. It is therefore the duty of the medical attendant on these occasions to see how far the person making the statement believes that his *death is impending* or approaching. This belief is considered in law to be equivalent to the obligation of an oath.

Hence, when the case is likely to prove fatal, it is the duty of the medical man to warn the patient in the presence of his relatives or friends, of his dangerous condition. If the wound or poison is not likely to prove rapidly fatal, the attendance of a magistrate to take down the statement in due legal form, would relieve the medical man of all responsibility. Should any statement, however, be made to him under these circumstances, it is his duty to make, on the spot, a note of the words actually used. There should be no paraphrase or translation of them, but they should be the *ipsissima verba* of the dying man. It is not for the witness, but for the court, to interpret what is thus stated. A medical man on these occasions should not render himself officious in extracting information. He may receive that which is *voluntarily uttered*, and either immediately or on the earliest possible opportunity, write down the statement as it was made. Any question should be simply confined to the purpose of explaining what may appear to him to be ambiguous, or contradictory in the declaration itself.

In reference to persons who have died from the effects of wounds, poison, or other violent causes, the initiatory proceedings connected with the inquiry usually take place in the court of the coroner ; and unless the medical man in attendance is supposed to be implicated by maltreatment, or otherwise, in the death of the person, the duty of making an examination of the dead body devolves upon him. He may not have seen the person while living ; and in this case it will be necessary that he should give his attention to those circumstances which may be of importance in the future inquiry. He should note as far as it can be ascertained : 1. The exact time of death, if known, and thus determine how long a period the person has survived. 2. The attitude, position, and condition of the body. 3. The state of the dress. 4. All surrounding objects. Any bottles, paper-packets, weapons, or spilled liquids

lying about should be collected and preserved, and regard to the body of deceased should be noted. 5. Things near the deceased should be collected. In making examination of the body the following additional points should be attended to: 6. The external appearance of the body, whether the face is livid or pallid. 7. Note the state of the countenance. 8. Note all marks of violence on the person, or discomposure of the dress, marks of blood, etc. 9. The situation, form, and direction of all wounds should be accurately noticed. 10. The presence or absence of warmth or coldness in the legs, arms, abdomen, mouth, or armpits. 11. The presence of cadaveric rigidity in any part of the body. To give any value to the two last-mentioned characters, it is necessary for the practitioner to observe the nature of the floor on which the body is lying, whether the body is clothed or naked, young or old, fat or emaciated. These conditions create a difference, in respect to the cooling of the body and the access of rigidity. 12. If found dead—When was the deceased last seen living, or known to have been alive? 13. Note all circumstances leading to a suspicion of suicide or murder. 14. The time after death at which the inspection is made. 15. Observe the state of the abdominal viscera. If the stomach and intestines are found inflamed, the seat of inflammation should be exactly specified; also all marks of softening, ulceration, effusion of blood, corrosion, or perforation. The stomach should be removed and placed in a *separate vessel*, ligatures being applied to the two ends. If cut open for examination at this period, this should be performed in a clean dish, and with such care that none of the contents are lost, or are allowed to mix with the contents of the intestines. 16. The contents of the stomach, if this organ is opened during the inspection, should be collected in a clean *graduated vessel*:—notice, *a*, the quantity; *b*, the odor tried by several persons; *c*, the color; *d*, acid or alkaline reaction; *e*, presence of blood, mucus, or bile; *f*, presence of undigested food; and here it may be as well to observe, that the presence of farinaceous matters (bread) would be indicated by the addition of iodine water, if the contents were not alkaline—of fat, by heat; *g*, other special characters. 17. The contents of the duodenum should be separately collected, ligatures being applied to it. 18. Observe the state of the large intestines, especially the rectum, and note the condition of their contents. The discovery of hardened feces in the rectum would prove that purging had not existed recently before death. 19. The state of the windpipe, throat, and gullet, whether there are in these parts any foreign substances, or marks of inflammation and corrosion. This is of essential importance, as it throws a light upon a variety of questions which may arise respecting death by suffocation from mechanical causes, or the nature of a substance swallowed. 20. The state of the lungs and heart; all morbid changes noted. 21. The state of the brain and spinal marrow. 22. The condition of the uterus, ovaries, and genital organs should be examined, as, in the female, poison has been sometimes introduced into the system by the vagina, or wounds have been inflicted internally. 23. The kidneys with the supra-renal capsules and the spleen should be submitted to examination. 24. The liver with the gall-bladder should be removed for a pathological and

chemical examination. 25. The urinary bladder, with any fluid contained in it, should be removed and placed in a separate jar.

Such are the points to which, in the greater number of cases of violent death, a medical jurist should give his attention. By means of these data, noted according to the particular case to which they are adapted, he will in general be enabled, without difficulty, to determine the probable time of death, and the actual means by which death was brought about. He may thereby have it in his power, if the case be one of poisoning, to point out the dish or article of food which had contained the poison, and to throw light upon any disputed question of suicide or murder, in relation to the deceased. Many cases of death from wounds or poison are rendered obscure, owing to these points not having been attended to in the first instance.

It is not necessary in this place to enter into any details respecting the mode of performing an *inspection*. A medical practitioner is supposed to have acquired a knowledge of this part of his duties during his study of anatomy; and any additional information which may be required will be found in the appropriate sections of this work. The only essential points in addition to those above mentioned are, 1. To examine all the important organs for marks of natural disease; and 2. To note down any unusual pathological appearances, or abnormal deviations; although they may at the time appear to have no bearing on the cause of death. It is useful to bear in mind on these occasions, that the body is inspected, not merely to show that the person has died from poison, but to prove that he has *not* died from any *natural cause*. Medical practitioners commonly give their attention exclusively to the first point; while lawyers, who defend accused parties, very properly direct a most searching examination to the last-mentioned point, *i. e.*, the healthy or unhealthy state of those organs which are essential to life. The usual causes of *sudden death* have their seats commonly in the brain, the heart and its great vessels, or in the lungs. Marks of effusion of blood, congestion, inflammation, suppuration, or a diseased condition of the valves of the heart, should be sought for and accurately noted. It has also been recommended that an examination of the spinal marrow should be made. If the cause of death be obscure after the general examination of the body, there is good reason for inspecting the condition of this organ.

[In medico-legal cases, involving the question of life and death, the examination of the body of the deceased cannot possibly be too thorough and exhaustive; the omission of any one organ is a radical defect. This is well illustrated in two leading cases in the United States within the year 1872,—that of Mrs. E. G. Wharton charged with poisoning General Ketchum, and that of Dr. Paul Schœppe charged with poisoning Miss Steinnecke. In neither case, was the post-mortem examination sufficiently complete. In the first case, where the symptoms of the deceased were certainly more in accordance with disease than with tartar emetic (the alleged) poisoning, and where competent medical authority ascribed it to cerebro-spinal meningitis, no examination of the spinal marrow was made. In the latter case, in which the symptoms were those of apoplexy and of uræmic poisoning, the kidneys and several

other organs were entirely overlooked. In certain obscure cases, it may even become necessary to institute a *microscopic* examination, especially of the brain and heart.—R.]

Exhumation of bodies.—Sometimes the inspection of a body is required to be made long after interment. So long as the coffin remains entire, there may be the expectation of discovering certain kinds of mineral poison in the organs; but decomposition may have advanced so far as to destroy all pathological evidence. The inspection in such cases is commonly confined to the abdominal viscera. The stomach is often found so thin and collapsed, that the anterior and posterior walls appear to form only one coat. This organ should be removed with the duodenum, and ligatures should be applied to each. The liver, spleen, and kidneys [and brain.—R.] should also be removed, in order that they may, if necessary, be separately analyzed. If poison is not found in one or more of these parts, it is not likely that it will be discovered in the body. It has been recommended that a portion of earth immediately above and below the coffin should be removed for analysis, as it may contain arsenic; but this appears to me to be an unnecessary piece of refinement when the coffin is entire, or when the abdominal parietes still cover the viscera. If decomposition has so far advanced as to have led to an admixture of earth with the viscera, and the poison is found in minute quantity in the tissues only, the source of the poison may be regarded as doubtful; and in this case, the earth in which the remains are found should undergo a chemical examination. The body of a deceased person when exhumed, should be *identified* by some friend or relative, in the presence of the medical examiner. In one case of murder by poison, the evidence almost failed, owing to this precaution not having been taken.

It is important that the viscera taken from a body which has been long in the grave should be sealed up immediately. They should not be allowed to come in contact with any metal, nor with any surface except that of clean glass, porcelain, or wood. It has been recommended that they should be washed with chloride of lime or carbolic acid; but this is decidedly improper; the use of any preservative chemical liquid would not only embarrass the future analysis, but would render a special examination of an unused portion of the liquid necessary, the purity of which would have to be unequivocally established. Preservation from air in clean glass vessels, with well-fitted corks covered with gut-skin, or what is still better, sheet-caoutchouc, is all that is required in practice.

Identity of substances.—It is necessary to observe, that all legal authorities rigorously insist upon proof being adduced of the *identity* of the vomited matters, or other liquids taken from the body of a deceased person, when poisoning is suspected. Supposing that, during the examination, the stomach and viscera are removed from the body, they should never be placed on any surface, or in any vessel, until we have first ascertained that the surface or vessel is perfectly *clean*. [It is safer and more satisfactory that all the vessels and apparatus used should be perfectly new.—R.] If this point be not attended to, it will be in the power of counsel for the defence to raise a doubt in the minds of the jury, whether the poisonous substance might not have been accidentally

present in the vessel used. This may be regarded as a very remote presumption; but, nevertheless, it is upon technical objections of this kind that acquittals follow in spite of the strongest presumptions of guilt. This is a question for which every medical witness should be prepared, whether he is giving his evidence at a coroner's inquest, or in a court of law. Many might feel disposed to regard matters of this kind as involving unnecessary nicety and care, but if they are neglected it is possible that a case may be at once stopped: so that the care subsequently bestowed upon a chemical analysis will be labor thrown away. Evidence of the presence of poison in the contents of a stomach was once rejected at a trial for murder, because they had been hastily thrown into a jar borrowed from a neighboring grocer's shop; and it could not be satisfactorily proved that the jar was clean and entirely free from traces of poison (in which the grocer dealt) when used for this purpose.

[A case has been communicated to the editor by Prof. R. Bridges, in which the search for arsenic in the body failed to detect that poison, but where *zinc* in considerable quantities was found. It turned out, on inquiry, that the stomach, etc. had been carelessly thrown into an old tin can, which had been formerly used for holding zinc paint, before being sent to the analyst.—R.] When the life of a human being is at stake, as in a charge of murder by poisoning, the slightest doubt is always very properly interpreted in favor of the accused.

Not only must clean vessels be used for receiving any liquid detained for subsequent chemical analysis, but care must be taken that the *identity* of a substance is preserved, or the most correct analysis, afterwards made, will be inadmissible as evidence. The suspected substance, when once placed in the hands of a medical man, should never be let out of his sight or custody. It should be kept sealed under his private seal, and locked up while in his possession, in a closet to which no other person has a key. If he has once let it out of his hands, and allowed it to pass through the hands of several other persons, then he complicates the evidence for the prosecution, by rendering it indispensable for these persons to state under what circumstances it was placed while in their possession. The exposure of a suspected substance on a table, or in a closet or room, to which many have access, may be fatal to its identity; for the chemical evidence, so important in a criminal investigation, will probably be altogether rejected by the court. When any article (*e. g.* a stomach or other organ) is reserved for analysis, care should be taken to attach immediately to it, or to the vessel containing it, a parchment or wooden label, upon which is plainly written, in ink, the name of the deceased and the date of removal, including the day of the week and month. This is especially necessary when there are two or more articles for analysis. I have known the greatest inconvenience to result from the neglect of this simple precaution. [This rule in relation to *identity* cannot be too rigorously enforced. A striking illustration is afforded in a recent case (*State of Virginia v. Mrs. E. E. Lloyd*, charged with poisoning her daughter with arsenic). At the trial, it was found that the person who had conveyed the stomach to the analyst, had died in the interim. Although several grains of arsenic were said to have been detected, still, as the identity of the stomach could not be *positively* estab-

lished, the court very properly ruled out the evidence for want of this single link in the chain.—R.]

Preserving articles for analysis.—In removing viscera or liquids from the body, and reserving them for analysis, it is necessary to observe certain precautions. A clean vessel with a wide mouth should be selected; it should be only sufficiently large to hold the organ, or liquid (the less air remaining in it the better); it should be secured by a closely-fitting cork, covered with gut-skin or bladder. Another piece of skin should then be tied over the mouth; or, for this, sheet caoutchouc or gutta-percha may be substituted with advantage. It should lastly be covered with tinfoil and a layer of white leather. In this way any loss by evaporation or decomposition is prevented, and the viscera may be preserved (in a cool place) for some time. If the mouth of the vessel be too wide for a cork, the other articles cannot be dispensed with. Paper only should not be used; I have known the appearances after death of the viscera of an infant, suspected to have died from poison, entirely destroyed by drying, from the evaporation which took place through the layers of paper with which the vessel in which they were contained was covered. The practitioner should bear in mind that all these matters are likely to come out in evidence; and whatever is worth doing at all is worth doing well. For reasons already stated, antiseptic chemical compounds should not be used. The addition of a small quantity of chloroform to the viscera will, without complicating the analysis, tend to preserve them.

The articles used for the preservation of viscera should be in all cases scrupulously examined. Some kinds of calico are dressed with arsenic and starch pastes, and many kinds of wrapping-paper as well as wall-papers are strongly impregnated with this poison. An observation made by Mr. Aickin, of Belfast, shows that this is not an unnecessary caution. This gentleman was engaged in examining the body of a child, in order to determine the cause of death. The organs were healthy, and as no sufficient cause presented itself, he removed the stomach, with a view of making an analysis of its contents. He was suddenly called away; and, to preserve the stomach, he wrapped it in a piece of paper (used for papering rooms), placing it on the uncolored side, and he locked it in a closet until the following day. Assisted by a friend, he then analyzed the contents, and found a trace of morphia, with a pretty large quantity of arsenic. As the symptoms from which the child had died were not those of poisoning with arsenic, and there were no appearances of the action of this substance on the body, he came to the conclusion that its presence must have been owing to some extraneous cause. He examined a portion of the wall-paper in which the stomach had been wrapped, and then found that part of it which was colored yellow was tinted with sulphide of arsenic or orpiment! It was therefore evident, as orpiment contains white arsenic, that the stomach and its contents had imbibed a portion of the poison during the night. ("Lancet," June 23, 1855, p. 632.) This satisfactorily accounted for the presence of arsenic under circumstances which might have given rise to a false charge of murder. Nearly all wall-papers having any tinge of green or golden yellow in them, contain arsenic, and this arsenic spreads by imbibition to other parts of the paper not so tinted. It would, of course, be proper to avoid

in all cases the use of any wrapper having upon it mineral colors of any description. Mr. Aickin's case shows in a striking point of view the danger of trusting to chemical analysis alone. Unless we look to physiology and pathology, a most erroneous opinion may be expressed.

The results of an analysis, in the shape of sublimes or precipitates, should be preserved as evidence, distinctly labelled in small glass tubes, hermetically sealed. They can then, if asked for, be produced for examination, at the inquest or trial.

On the use of Notes.—It has already been recommended, as a rule in these criminal investigations, that a practitioner should make notes of what he observes in regard to symptoms, appearances after death, and the results of a chemical analysis. His own observations should be kept distinct from observation given him by others. He may base his conclusions on the former, but not on the latter. From the common forms of law in this country, a person charged with the crime of poisoning may remain imprisoned, if at a distance from the metropolis, for some months before he is brought to trial. It is obvious, however clear the circumstances may at the time appear to a practitioner, that it will require more than ordinary powers of memory to retain, for so long a period, a distinct recollection of all the facts of the case. If he is unprovided with notes, and his memory is defective, then the case will turn in favor of the prisoner, for he will be the person to benefit by the neglect of the witness. In adopting the plan here recommended, such a result may be easily prevented. It may be remarked that the law relative to the admissibility of notes or memoranda is very strict, and in trials for murder is rigorously enforced by the judges. In order to render such notes or memoranda admissible, it is indispensably necessary that they should be taken on the spot at the time the observations are made, or as soon afterwards as practicable; and, further it must be remembered that a witness can refer to them only to refresh his memory. If from indistinctness of writing or other causes, a copy of the notes has been subsequently made, a witness should not destroy the original notes, but have them ready for production. [See on this subject "Greenleaf's Evidence," vol. i. §§ 436-439. Also, "Alison's Treatise on the Practice of the Criminal Law," pp. 540-542. —P.]

So in reference to all other written memoranda connected with the case as to the medicines prescribed for the deceased, the visits made to him, etc., the witness should be prepared to produce them and explain any alterations or erasures which may be found in his books. Counsel are entitled to look at and examine all documents of this kind which are produced or used by the witness in giving his evidence.

Medico-legal Reports.—One of the duties of a medical jurist is to draw up a report of the results of his examination: 1, in regard to symptoms; 2, in regard to appearances after death; and, 3, in regard to the results of an analysis. With respect to the first two divisions of this report, I must refer the reader to the rules for investigating cases of poisoning (p. 23). It need hardly be observed that the time at which the person was first seen, and the circumstances under which the attendance of the practitioner was required, as well as the period of death, should be particularly stated. The hour, the day of the week,

and the month, should be invariably mentioned. Some medical witnesses merely state the day of the week, without that of the month, or *vice versa*. At a trial this sometimes creates great confusion, by rendering a reference to almanacs necessary. The words yesterday, next day, etc., should never be used. The facts which it will be necessary to enter in the report are specially stated under the heads of investigation (see p. 23). If these facts are not observed in the order there set down, their value as evidence of the cause of death, or of the criminality or innocence of particular persons, will be entirely lost.

In drawing up a report of symptoms and appearances after death, the facts should be in the first instance plainly and concisely stated *seriatim*, in language easily intelligible to non-professional men. A reporter is not called upon to display his erudition, but to make himself understood. If technical terms are employed, their meaning should be stated in parentheses. When a subject is thoroughly understood, there can be no difficulty in rendering it in simple language; and when it is not well understood, the practitioner is not in a position to make any report. Magistrates, coroners, and barristers are very acute, and easily detect ignorance, even when it appears under the mask of erudition.

In recording facts, a reporter should not encumber his statements with opinions, inferences, or comments. The facts should be first stated, and the conclusions should be reserved until the end of the report. The language in which conclusions are expressed, should be precise and clear. It must be remembered that these are intended to form a concise summary of the whole report, upon which the judgment of a magistrate, or the decision of a coroner's jury, will be ultimately based. They should be most strictly confined to the matters which are the subject of inquiry, and which have actually fallen under the observation of the witness. Thus, they commonly refer to the following questions: What was the cause of death? What are the medical circumstances which lead you to suppose that death was caused by violence? What are the circumstances which lead you to suppose that death was *not* caused by natural disease? Answers to one or all of these questions comprise, in general, all that a reporter is required to introduce into the conclusions of his report.

The reporter must remember that his conclusions are to be based only upon *medical* facts—not upon moral circumstances, unless he is specially required to express his opinion with regard to them when they are of a medico-moral nature. Further, they must be founded only on what *he has himself seen or observed*. Any information derived from others should not be made the basis of an opinion either in evidence, or in a medico-legal report. It is scarcely necessary to remark that a conclusion based upon mere *probabilities* is of no value as evidence.

In drawing up a report on the *results of a chemical analysis*, the following rules may be borne in mind. A liquid or solid is received for analysis: 1. When, and of whom, or how received? 2. In what state was it received—secured in any way, or exposed? 3. If more than one substance received, each to be separately and distinctly labelled; appearance of the vessel, its capacity, and the quantity of liquid (by measure) or solid (by weight) contained therein. 4. Where and when

did you proceed to make the analysis, and where was the substance kept during the intermediate period? 5. Did any one assist you, or did you make the analysis yourself? 6. Physical characters of the substance. 7. Processes and tests employed for determining whether it contained poison. All the steps of these processes need not be described: a general outline of the analysis will suffice. The magistrate may thus satisfy himself by an appeal to others (if necessary) whether the analysis has or has not been properly made. 8. Supposing the substance to contain poison—is this in a pure state, or mixed with any other body? 9. The strength of the poison, if an acid, or if it be in solution: in all cases, the quantity of poison found, determined if possible by actual weighing. 10. Supposing no poison to be contained in it, what was the nature of the substance? Did it contain anything of a noxious nature, *i. e.*, likely to injure health, or destroy life? 11. Could the supposed poisonous substance exist naturally, or be produced within the body? 12. Was it present in any of the liquids or solids employed in the chemical analysis? 13. Was it contained in any of the articles of food or medicine taken by the deceased? 14. Is its presence to be ascribed to the use of any mineral matter employed by injection after death for the preservation of the body of the deceased? 15. What quantity of poison was actually separated in the free or absorbed state? 16. How much of the substance found would, under the circumstances, be likely to destroy life?

There are few reports in which answers to some of these questions, although not formally put, will not be required; and unless the whole of them are borne in mind by the operator at the time an analysis is undertaken, those which are omitted can never receive an answer, however important to the ends of justice that answer may ultimately become.

There are frequently defects in these reports which it is desirable to point out. The statements are sometimes drawn up in exaggerated language; at others they are overloaded with technical and therefore unintelligible terms, and the writer is seldom sufficiently careful to keep his facts distinct from his comments. The former may be useful as evidence; the latter are inadmissible. With respect to the first of these defects, it is very much the practice of medical men, in drawing up reports of medical cases for professional purposes, to use, unthinkingly, exaggerated language. Thus, it may be observed in the description of an ordinary post-mortem examination, the lining-membrane of the stomach is described as being "intensely" inflamed, or some part is "considerably" injected, or a cavity is "enormously" distended. Expressions thus loosely employed, convey to the legal mind a widely different meaning from that intended by the reporter. They create also great difficulty in evidence if withdrawn or modified, a change which other circumstances may show to be necessary, and at the same time they place the witness in an undesirable position before the court. On the other hand, if retained, they may render the facts unsusceptible of explanation upon any theory of natural disease. Such descriptions obviously imply a comparison with similar conditions in numerous other dead bodies; but what is the standard by which they are really measured, and what opportunity has the witness had of creating such a standard from his own experience?

In general it will be found that such expressions have been used without proper consideration from a habit acquired by the witness in reporting cases for the information of medical men only. Let him who is inclined to use them, bear in mind that barristers look much more closely to the strict meaning of words than medical men, and that they are always disposed to distrust the judgment of one who cannot speak or write without resorting to the use of the superlative degree.

The free use of *technical terms* in drawing up reports should be avoided. Putting aside those cases in which a medical man believes that he is displaying his erudition by the selection and use of such terms, there can be no doubt that the greater number of medical practitioners fall into this practice from mere habit. They think they are addressing the report to the president and members of some medical society, instead of a coroner and jury who have never in their reading or experience met with such terms, and to whom, therefore, they are perfectly unintelligible. In a report on the appearances in the body of a man who had suffered from chronic insanity, which was submitted to me for explanation, the following passage occurred: "The only morbid appearance in the brain was an atheromatous deposit in the pons Varolii, near the situation of the locus niger." In another document, the reporter stated, for the information of a coroner's jury, that the "integuments of the cranium were reflected, and the calvarium was exposed." If a reporter will use such terms as these or others of a similar kind, such as "parietes of the abdomen," "epigastrium," "hypertrophy of the liver," when it would require no more trouble to put what he means in plain English, he must be prepared to have his meaning perverted, or wholly misunderstood. Setting aside the men who act as jurors, it may be observed that educated persons, such as coroners and magistrates, do not commonly include professional terms within the range of their studies. There are but few of them who understand the difference between perineum and peritoneum, or the meaning of the words hemispheres of the brain, pia mater, puncta cruenta, corpora quadrigemina, centrum ovale, etc. They are not likely to know the difference between the cardia and pylorus, nor the nature or situation of the duodenum, jejunum, ileum, or cæcum, and are as ready to consider them to be parts of the liver or urinary bladder, as of the intestines. On one occasion, I heard a learned judge ask for an explanation of the meaning of the term "alimentary canal." A slight consideration will show to any medical practitioner that refined professional language is wholly misplaced in a report which is intended to inform and convince the minds of ordinary men upon plain matters of fact.

The last point which calls for comment in reference to medical reports, is the loose manner in which facts and comments on facts, as well as hearsay statements, are sometimes found blended. If a reporter takes care to eliminate facts from comment, his report is admissible, and may be read at the inquest or trial as evidence. The facts are for the jury; the comments upon the facts, introduced by the reporter, may or may not be correct, and are, therefore, not evidence. Their correctness or relevancy to the case will be elicited in the cross-examination. As a rule, nothing should be entered in a report which is not connected with

the subject of inquiry, and which has not actually fallen under the observation of the reporter. The introduction of hearsay statements, *i. e.*, statements made by others, or of circumstances which have come to his knowledge through public rumor, should be carefully avoided.

Upon the medical report, and such evidence as may be required to explain it, an accused person may be committed for trial at the Assizes, either by a coroner or a magistrate. In the first stage of the proceedings, under these circumstances, the medical witness goes before the grand jury, and there, after the administration of an oath, he is required to make a general statement of what he knows of the matter. Such questions are put as may be necessary to elucidate the cause of death; and on the finding of a true bill for murder or manslaughter, the accused is placed upon his trial before one of the learned judges of Assize. According to the variable circumstances attending such cases, the medical evidence is called for at an early, or late stage of the proceedings. When it is at all doubtful whether the cause of death was owing to any criminal act, it is called for at the commencement of the case, in order to lay a foundation for further inquiry.

It is necessary that a medical witness should remember that copies of his report and depositions, either before a coroner or magistrate, are usually placed in the hands of counsel as well as of the learned judge, and that his evidence, as it is given at the trial, is compared word for word with that which has been already put on record. There is reason to believe that this is not generally known to members of the medical profession, and thus it happens that either from failure of memory, want of accurate observation, or carelessness in giving evidence at a coroner's inquest, medical witnesses lay themselves open to severe censure, either by stating matters differently at the trial, or by giving a very different complexion to the facts. Any serious deviations from what is on record will of course tell unfavorably for the witness, supply materials for a severe cross-examination, and form an excellent ground of defence for the prisoner. The witness's weakness is the prisoner's opportunity, and of course his counsel will not lose the occasion of impressing upon the jury that a man who can on oath give two different accounts of the same transaction, is not to be believed on either.

[*Dying Declarations.*—“The general principle on which this species of evidence is admitted was stated by Lord Chief Baron Eyre to be this: That they are declarations made in extremity, when the party is at the point of death, and when every hope of this world is gone; when every motive to falsehood is silenced, and the mind is induced by the most powerful considerations to speak the truth. A situation so solemn and so awful is considered by the law as creating an obligation equal to that which is imposed by a positive oath in a court of justice.

“It was at one time held by respectable authorities that this general principle warranted the admission of dying declarations in all cases, civil and criminal; but it is now well settled that they are admissible, *as such*, only in cases of homicide, ‘where the death of the deceased is the subject of the charge, and the circumstances of the death are the subject of the dying declaration.’

“The persons whose declarations are thus admitted are considered as

standing in the same situation as if they were sworn ; the danger of impending death being equivalent to the sanction of an oath. It follows, therefore, that *where the declarant, if living, would have been incompetent to testify, by reason of infamy or the like, his dying declarations are inadmissible* ; and, as an oath derives the value of its sanction from the religious sense of the party's accountability to his Maker, and the deep impression that he is soon to render to Him the final account ; *wherever it appears that the declarant was incapable of this religious sense of accountability, whether from infidelity, imbecility of mind or tender age, the declarations are alike inadmissible.*

“ On the other hand, as the testimony of an accomplice is admissible against his fellow, the dying declarations of a *particeps criminis* in an act which resulted in his own death, are admissible against one indicted for the same murder.” *Ib.* § 157. On principle, therefore, the dying declarations of an accomplice should, to justify a conviction, require the same corroboration that is necessary where he testifies as a living witness (see Joy on the Evidence of Accomplices) ; but as to this the judges in *Tinckler's* case (1 East. Pl. Cr. 354–56) were divided, the majority, however, thinking that they were sufficient without corroboration. And as husband and wife may testify against each other in all cases of personal injuries inflicted by either upon the other, the dying declarations of either are admissible where the other party is charged with the murder of the declarant. *The People v. Green*, 1 Denio R. 614.

It is essential to the admissibility of these declarations, and is a *preliminary fact, to be proved by the party offering them in evidence*, that they were made under a *sense of impending death*.

It is not essential, however, that the consciousness of impending death should be expressed by the dying man himself ; it may be collected either from the circumstances of the case, as the nature of the wound and state of the body, or from expressions used by the deceased. *Com. v. Murray*, 2 Ash. 41 ; *Com. v. Williams*, *Ib.* 69 ; *State v. Gillick*, 7 Clarke (Iowa) 287 ; *State v. Nash*, *Ib.* 347. See also *People v. Lee*, 17 Cal. 76 ; *People v. Ybarra*, *Ib.* 166 ; *Kilpatrick v. Commonwealth*, 7 Casey 198.

The length of time which elapses between the declarations and the death furnishes no rule as to the admissibility or rejection of the evidence. In *Woodcock's* case, 2 Leach's Cr. Cas. 563, the declarations were made forty-eight hours before death ; in *Tinckler's* case, 1 East. P. C. 345, ten days, and in *Rex v. Mosley*, Cr. Cas. 97, eleven days before death ; and all were received. It is the *impression* of almost immediate dissolution, and not the rapid succession of death in point of fact that renders the testimony admissible. Hence, where declarant at the time believed his death to be impending and certain, the declarations were competent, notwithstanding that he subsequently revived, and thought he might recover. *State v. Nash*, 7 Clarke (Iowa) 347.

The language of the text-books, and of the authorities generally, is, that “ where it appears that the declarant had ‘any hope’ of recovery, however slight it may have been, and though death actually ensued shortly afterwards, the declarations are inadmissible.” 1 Greenleaf § 158 ; Phillips on Evidence 200. But in *Regina v. Pym* (“ Law Times,” 1846, p. 500), where it appeared that the declarant had a firm belief

that death was approaching, although it appeared that he *hoped* and thought it not *impossible* that he might recover. ERLE, J., in admitting the evidence, said: "It has no doubt been held in some cases that *all hope* must be given up, but this is now decided not to be necessary. Indeed, if it were so, no declarations could be received, for scarcely a human being could be found, under any circumstances, who would not retain some *hope*. The law admits these declarations, not because recovery is impossible, but because there is a *conviction* of approaching death."

The word *hope* is used in two senses: first, as implying *belief*, *expectation*; and second, *wish* or *desire*. In the latter sense it must always exist, and that seems to be the meaning as used in the case last cited. Where it is used as synonymous with belief or expectation, its existence would render the declarations inadmissible; since "hoping" in that sense to recover would be wholly inconsistent with the alleged belief that death was impending.

The declarations are admissible only as to those things which declarant would have been competent to testify if sworn in the case, viz., *relevant facts*, not mere matters of *opinion*.

They are admissible in favor of, no less than against the party charged with the death.

It is no objection to their admissibility that they were elicited by leading questions, or by pressing and earnest urgings. They must, however, be complete in themselves: for if it appears that the declarant intended to connect them with or qualify them by, other statements, which he is prevented by any cause from making, they will not be received. 1 Greenleaf, § 159.

The circumstances under which the declarations were made are to be shown to the judge; it being his province, and not that of the jury, to determine whether they are admissible. *Com. v. Murray*, 2 Ash. 41; *McHugh v. State*, 31 Alabama 317; *People v. Glenn*, 10 Cal. 32; *State v. Howard*, 32 Vermont 380.

Still, however, the credibility of the evidence is entirely with the jury, who, if *they* do not believe that the deceased really was in such circumstances as the other witnesses may have testified to, may give no weight to the declarations.

If the statement of the deceased was reduced to writing, and signed by him, it must be produced, if existing, and secondary evidence of the declarations cannot be admitted. *State v. Tweedy*, 11 Iowa 350. But it is essential that a subscribing witness thereto should be produced, or his absence accounted for. *McHugh v. State*, 31 Ala. 317. And where the declarations had been repeated at different times, at one of which they were under oath, and informally reduced to writing by one witness, and at the others they were not, it was held that the latter might be proved by parol, if the other could not be produced. *Rex v. Reason*, 1 Str. 499, 500; *State v. Tweedy*, *supra*. So, if the deposition has been taken, and is inadmissible as such for want of compliance with some statutory requirement, it seems it may still be treated as a dying declaration.

Great caution, however, is to be observed in the use of this kind of evidence, because it is to be recollected that the accused may not have

been confronted with declarant, nor does he ever have the power of *cross-examination*, which is quite as essential to the eliciting of all the truth as the obligation of an oath can be. Besides which, the particulars of the evidence, to which the deceased has spoken, are in general likely to have occurred under circumstances of confusion and surprise, calculated to prevent their being accurately observed; and leading both to mistakes as to identity of persons, and to the omission of facts essentially important to the completeness and truth of the narrative. 1 Greenleaf, § 162; Evans's Pothier on Obligations 255.

In the case of *Commonwealth v. Lamb*, tried in the Oyer and Terminer of Philadelphia, in March, 1854, the deceased, who died from the effects of blows upon the head inflicted by a gang who attacked him in the dark, had declared positively that the defendant was the person who had struck him. The declarations were not received because of failure in the preliminary proof, and the prosecution was abandoned. The defendant was a very respectable young man, and could have clearly established his innocence, but the case showed how little reliance can be placed on this species of evidence, especially in questions of identity. (See, also, a case mentioned in the former edition of this work, p. 179.)

The objection, that receiving dying declarations was a violation of the article of the Declaration of Rights that every subject shall have a right to confront the witnesses against him face to face, has been made, but not sustained by the courts. *Com. v. Carey*, 12 Cush. (Mass.) 246; *Burrell v. State*, 18 Texas 713; *People v. Glenn*, 10 Cal. 32; *State v. Nash*, 7 Clarke (Iowa) 347.

It is to be observed that while dying declarations are restricted to the case of trial for the homicide of the declarant, this applies only to declarations offered on the sole ground that they were made *in extremis*; for where they constitute part of the *res gestæ*, or come within the exception of declarations against interest, or the like, they are admissible as in other cases; irrespective of the fact, that the declarant was under apprehension of death.

It is evidently, however, no part of the duty of the medical witness or other person present when declarations are made to determine whether they will be admissible or not. This question is to be left to the judges before whom the case shall be tried; and the witness should carefully remember what is stated, writing it down immediately, or at the earliest moment possible, stating *all* that was said, and using the *identical language* of the declarant, not simply giving what he conceives to be the meaning or substance of it.—P.]

CHAPTER II.

CORONERS' INQUESTS.—TRIAL AT THE ASSIZES.—SUBPŒNAS.—MEDICAL FEES.—EXAMINATION IN CHIEF.—DUTIES OF MEDICAL WITNESSES.—QUOTATIONS FROM BOOKS.—PRESENCE IN COURT.—LICENSE OF COUNSEL.—RULES FOR THE DELIVERY OF EVIDENCE.

Coroners' inquests.—The proceedings at coroners' inquests are treated too lightly by medical men. The ignorant and uneducated class of persons who often constitute the jury, as well as the circumstances under which the inquiry usually takes place, are not calculated to inspire great respect for these initiatory proceedings; but still by law and custom coroners' inquisitions are and have been for ages in this country, the only tribunals for inquiring into and determining the cause of death in cases of suspected violence; and they are therefore deserving of more attention than is usually shown to them by medical witnesses. As a rule, in all inquests which are likely to end in a committal of the accused person, a medical man who is giving his evidence before a coroner, in the room of a small country inn, or in a village school-room, is virtually delivering it before a judge of assize; and this fact alone, if not a respect for the court, should induce him to give the evidence guardedly, and with a due consideration to the serious results to which it may ultimately lead. The 4th Edward I. stat. 2, on which coroners profess to act, directs that "upon information," they shall "go to the place where any be slain or suddenly dead," and make due inquiry as to the cause, etc., before a jury selected from persons living in the neighborhood. The information upon which a coroner generally acts is, 1. Notice from a beadle, or other officer of the parish (whose zeal is sometimes stimulated by a fee or salary), of any death from sudden or supposed unusual causes. 2. Notice from a medical man who may have attended the deceased, and who communicates his suspicion that the cause of death is not natural. 3. Notice from a registrar of deaths that no cause has been assigned in a particular case, or that there has been a rapid death after a short illness. The conclusion to which experience leads in reference to these inquiries is, that the system affords no certainty for the detection of crime; that it affords no protection to those who are wrongly charged with crime; and lastly, that in some cases it screens a criminal by a verdict based upon an imperfect inquiry, in which the important medical facts are either not understood, or are misinterpreted by the jury.

Many persons who occupy the office of coroner are neither medically nor judicially qualified for the proper performance of the duties of the office. The system of electing a man to hold such an office as this (one demanding special *medical* knowledge of the causes of death, and good

legal knowledge of the law of evidence) by freeholders of the lowest degree, is so intrinsically absurd, that it is quite wonderful how, with improved civilization, it has maintained its ground in such a country as England. The election of a Lord Chancellor, of the judge of our courts of law, or of County Court judges, might be with equal reason left in the hands of voters of this class, men who have no knowledge of the duties of the office, or of the skill and learning required in one who is really competent to fill it. The election of a good and capable person as coroner is, therefore, a matter of pure accident. No preliminary test of ability or capacity is required. [The same is lamentably true in most parts of the United States; the office being usually the bestowal of political favoritism.—R.]

In Scotland, the office of coroner does not exist, but in place of this, there is an officer named Procurator Fiscal, generally a skilled solicitor, nominated by competent authority, and not elected by scot and lot voters. The general order issued to these officers by the Lord Advocate, enjoins that in cases where a dead body is discovered, the Procurator Fiscal shall obtain a medical report of the cause of death; and in cases of persons found dead, the body is generally inspected for this purpose. This, however, is at the option of the appointed officer, the instruction being in these words: "Wherever, in his opinion, a written medical report is necessary for the due consideration of the case, he, the Procurator, shall obtain such a report from a duly qualified medical practitioner." The usual practice in England is to select the *nearest* medical man, whether he has had any experience or not, and often to trust an important and delicate pathological and chemical inquiry in the hands of one who probably has never before made an inspection or an analysis.

Under the present system coroners are empowered by the Medical Witnesses' Act (6 and 7 William IV. c. 89) to issue an order for the attendance of any legally-qualified practitioner, "being at the time in actual practice in or near the place where the death has happened;" a fee of two guineas is the maximum allowed for making a post-mortem examination, and, if considered necessary by the jury, a chemical analysis of the stomach and intestines. A penalty of five pounds is attached to disobedience of this order, except for reasonable cause. Mr. Rumsey has correctly represented the unsatisfactory position in which medical men are placed by such an arrangement. He observes: "It is no discredit to a practitioner engaged in the toilsome routine of ordinary medical duties, if he should feel himself at a loss when called upon for a decisive opinion in some obscure case of poisoning or infanticide. His scanty opportunities for the study of these subjects and for making post-mortem examinations cannot suffice to qualify him for answering the delicate and important questions which he must answer before a jury can find a proper verdict." . . . "The custom of indiscriminately summoning medical practitioners of all sorts, and of all degrees of pathological knowledge and forensic skill, has sadly depreciated the value of medical evidence in courts of justice. Public confidence in the profession has been shaken, and the appearance of a 'doctor' in the witness-box is but too often a signal for sport among gentlemen of the long robe."

("Essays on State Medicine," p. 356.) Under such a loose and imperfect system, the results must necessarily be disastrous.

No medical man can be compelled to undertake that which he feels incompetent to perform, and some medical practitioners who have felt this want of experience have properly declined to make chemical analyses involving so serious a responsibility. It is thus that, in many cases of importance, analyses for coroners' inquests are now referred to chemical experts, and the practitioner discharges himself of that responsibility which the Medical Witnesses' Act imposes upon him without any adequate remuneration.

Before quitting this subject, it is necessary to observe that medical men are too ready to give their opinion of the cause of death for a coroner's inquest without making an inspection of the body. No man is compelled to give an opinion upon insufficient data, and if by the institution of a judicial inquiry there are grounds for believing that a death has not been natural, no medical opinion of the case should be given in the absence of an inspection. Such an opinion must always be conjectural, and may involve the medical man in an unpleasant responsibility.

Trial at the Assizes.—The next stage of the proceedings in a criminal case brings a medical witness before a superior court. For this purpose a *subpœna* is issued. It need hardly be observed that every witness is bound to obey a subpœna, when with it his reasonable expenses for journey, etc., are tendered to him, but he is not bound to attend at the trial except upon a subpœna. [In criminal cases no tender of fees, etc., is in general necessary on the part of the government, in order to compel its witnesses to attend; it being the duty of every citizen to obey a call of that description, and it being also a case in which he is himself in some sense a party. But his fees will in general be finally paid from the public treasury. In all such cases, the accused is entitled to have compulsory process for obtaining witnesses in his favor. (1 Greenleaf's Ev. § 311.)—P.]

There are some questions connected with this subject which it will be proper to consider in this place. *If a subpœna is served on an ordinary or skilled medical witness, is he bound to obey it?* In *Betts v. Clifford* (Warwick Lent Assizes, 1858) the later Lord Campbell stated, in answer to a question, that a *scientific witness* was not bound to attend upon being served with a subpœna, and that he ought not to be subpœnaed. If the witness knew any question of *fact*, he might be compelled to attend, but he could not be compelled to give his attendance to speak to matters of *opinion*. In *Rich v. Pierpoint*, an action for malapraaxis, Dr. Lee was summoned against his will to give evidence on the part of the plaintiff. He stated that on the evening before the trial a solicitor called on him, and left a subpœna with him. Dr. Lee would not hear any account of the case which the solicitor proposed to give, and expressed his resolutions to have nothing to do with the trial. The solicitor informed him that he would be required to pay the usual penalty if he did not attend. He went down to Kingston, and was warned not to leave the court until the trial was over. He heard the evidence on the part of the plaintiff, and upon this and the medical evidence he gave his opinion—not much in favor of the party who summoned him, and not

much against him. Dr. Lee considered that he could not avoid attending the trial under these circumstances. ("Medical Times and Gazette," April 12, 1862, p. 389.)

In the case of *Webb v. Page* ("Carrington's and Kirwan's Reports," p. 23) the late Mr. Justice Maule ruled as follows: "There is a distinction," said his lordship, "between the case of a man who sees a fact and is called to prove it in a court of justice, and that of a man who is selected by a party to give his opinion on a matter on which he is peculiarly conversant from the nature of his employment in life. The former is bound, as a matter of public duty, to speak to a fact which happens to have fallen within his own knowledge—without such testimony the course of justice must be stopped. *The latter is under no such obligation*; there is no such necessity for his evidence, and the party who selects him must pay him." In the case referred to by Mr. Justice Maule, a skilled witness had been subpoenaed, but he refused to give evidence unless he was first paid for his services and loss of time. ("Medical Times and Gazette," April 26, 1862, p. 432.) A barrister, who quotes this ruling, goes on to say: "There is one reason why I should not advise any person in the position of a skilled witness totally to disregard a subpoena. It is quite clear that should such a person fail to attend a trial no attachment could issue, even if he were called as is usual upon the subpoena, because the party subpoenaing him could not make the requisite affidavits that he was damnified by the witness's absence, and in what respect. But such party might bring an action for damages; and although he would recover none, he might not only worry, but might even put the defendant to a considerable expense, as taxed costs by no means include the entire costs in such cases. Although, therefore, I could not advise a total neglect of a subpoena, the safest course would be to obey it, and demand expenses before giving evidence. Such expenses would be only those allowed for a professional witness (not special fees), but if the person so subpoenaed were willing to run the risk of an action, he might safely absent himself without any fear of an attachment from the court for contempt." With regard to the question whether a skilled witness would be permitted to demand a high fee for his attendance under such circumstances, the writer adds: "To permit him legally to demand a high fee would perhaps look somewhat like legally countenancing a bribe." At all events there is no such legal recognition.

In a case which came before the Court of Exchequer in May, 1868 (*Marsted v. Morris*), a witness wilfully disobeyed a subpoena. In consequence of this the trial was postponed, and the parties were put to great expense. An arrangement was made by which the witness bound himself to pay a part of the expenses. The *Chief Baron* said: It must be distinctly understood that in all cases where it appeared to the court that there had been a wilful disobedience of a subpoena after proper service, such a contempt of court would be visited with the punishment it deserved. *Martin, B.*: It was not to be tolerated that a man should exercise any discretion as to whether he would or would not attend a court in pursuance of a subpoena. Enormous costs were incurred in preparing a case and bringing it down to trial, the whole of which were to be thrown away and wasted, because a man refused to obey a lawful

summons to attend as a witness. *Pigott, B.*: A subpoena was not to be treated as mere waste paper. Public justice required that persons wilfully committing contempt of court should be dealt with in such a manner as to teach them that they could not commit a contempt of court with impunity.

Lord Campbell's dictum in reference to the distinction between fact and opinion confers no practical benefit on witnesses. It is at all times difficult in science, and in the medical sciences particularly, to separate them; and if a man appears to testify to a medical or scientific fact, he cannot avoid giving an opinion arising out of the fact. In a recent action against a druggist for a mistake in compounding medicine, an attempt was made to procure my *opinion* as a skilled witness at the trial, by reason of *facts* obtained from the report of a chemical analysis, the real object of which was, at the time, entirely concealed. The suit was fortunately compromised, and my attendance was not necessary, but such a case should convey a caution to chemical experts. They may be employed secretly and under untrue statements to make analyses; these become *facts* on which they may be summoned like ordinary witnesses to give *opinions*, as skilled witnesses, while the payment of the usual fee for a skilled witness is evaded.

It would appear from the case of *Maskerry v. O'Connor*, Q. B., June, 1873, that medical gentlemen residing within the Bills of Mortality are in this respect placed under exceptional circumstances. The plaintiff, a girl, seven years old, appeared by her father, claiming damages of defendant by reason of personal injuries sustained from careless driving. Dr. P. Leslie was called to prove the nature of the injuries, and he declined to give evidence unless his medical fees were first paid. It appeared that he had been served with a subpoena without any fee. A shilling was then tendered to him, but he still declined to give evidence until either his expenses were paid or there was an undertaking to pay them. Quain, J., ruled that as Dr. Leslie resided within the "Bills of Mortality," all that he was entitled to was one shilling on his subpoena! The witness then produced a report of a case in which a medical man had successfully insisted on his fees being paid before giving evidence, but it appeared that he did not reside within the Bills of Mortality. Dr. Leslie was accordingly sworn. The jury returned a verdict of damages against defendant, and the judge refused to certify. It may be remarked of these Bills, which were commenced in 1592, that since 1840 they have been superseded in fact but not in law by the Registrar-General's weekly returns. They included latterly 148 parishes in Middlesex and Surrey, but excluded the large parishes of Marylebone and St. Pancras. The payment of medical witness fees should not depend upon the witness living within or without an antiquated boundary of this kind.

Skilled scientific witnesses are often placed in a very invidious position in reference to fees. They are bound to obey a subpoena, but unless they make a special arrangement with the party summoning them, they cannot claim a proper remuneration for their services. In the case of *Pritchard v. McMahon* (Nov. 1878), plaintiff, a veterinary surgeon, was served with a subpoena by defendant, receiving at the time a guinea for conduct-money. He held himself in readiness to attend the trial,

involving scientific evidences regarding some horses, for a period of nine days. He claimed two guineas a day for his loss of time, and five guineas for the day on which he attended the trial. Another guinea was tendered to him before action, but this he declined to accept, and it was paid into court. Mellor, J., upon these facts, directed judgment to be entered for the defendants, following a case in the Court of Queen's Bench, in which it was held that as the witness was bound to obey the subpoena, there was no consideration for any promise which could be inferred on the part of the person serving him to pay him any special fee.

In a case tried at the Carnarvon Assizes, August, 1872, a medical man had refused to sign the depositions which had been taken before the magistrate without being guaranteed a higher fee than that allowed by the county tariff. Bovill, C. J., told the witness that the Act of Parliament imposed an obligation upon him, and he had no power to refuse, and if he did so on another occasion he would be liable to be indicted for disobedience. The judge held that a medical man has no right to fix the amount of his expenses, but must always take the allowance which the law gives him. ("Lancet," 1872, vol. ii. p. 204.)

[My legal friend, J. Levering Jones, Esq., has kindly looked up for me the laws of the United States in relation to fees to medical experts. Only two cases have been found to be exactly in point, and one decision is in direct opposition to the other. In *Ex parte Dement*, 53 Ala. 389, it was decided that a physician or surgeon can be compelled to testify as an expert, where such testimony is relevant to a case pending for determination in a judicial tribunal, without being paid as for a professional opinion. Refusal to testify may be punished as a contempt.

In *Buchman v. State*, 59 Indiana 1, the court held that a physician or surgeon, testifying as an expert, by giving his opinion is performing a strictly professional service; and he may require a professional fee before testifying. A refusal to testify unless compensated will not be a contempt. The latter decision is in principle sustained by the cases of *People v. Montgomery*, 13 Abb. Prac. Rep., N. S., 207; *Blythe v. State*, 4 Ind. 525; *Webb v. Baird*, 6 id. 13; and *Dills v. State*, 59 id. 15, 23. The law, as defined in *Buchman v. State*, is certainly supported by the weight of authority, but other decisions will be necessary to make that one unimpeachable.—R.]

Medical Witnesses.—Assuming that the medical man has obeyed a subpoena, he will now be required to attend before the court, and to state, in the face of adverse counsel, the opinions which he has formed from the medical facts of the case, as well as the grounds for these opinions. He will then, for the first time, undergo the ordeal of a public examination. Some medico-legal writers have considered it necessary to lay down rules respecting the manner in which a medical witness should give his evidence; how he is to act on a cross-examination, and in what way he is to recover himself on re-examination. Any advice upon this head appears to me to be quite superfluous; since experience shows that these rules, like those given to prevent drowning, are invariably forgotten at the very moment when a person is most in need of them. A medical man who goes to testify to the truth to the best of his ability should bear in mind two points: 1. That he should be well prepared on all parts of

the subject on which he is about to give evidence. He should act on these occasions upon the advice contained in the Latin motto, *ne tentes aut perfice*. 2. That his demeanor should be that of an educated man, and suited to the serious occasion on which he appears, even although he may feel himself provoked or irritated by the course of examination adopted. A medical witness must not show a testy disposition in having his professional qualifications, his experience, his means of knowledge, or the grounds for his opinions very closely investigated; he should rather prepare himself to meet with good humor the attempts of an adverse counsel to involve him in contradictions, and show by his answers that he has only a desire to state the truth. Law and custom have long established that a barrister, in defending a prisoner charged with murder, has a right to make use of all fair, and even what may appear to the witness unfair means for the defence. It is no part of his duty to argue on his adversary's side, or to constitute himself a witness on his own side. It is a distinct breach of his duty to bear false witness by the adducing either of untrue facts, or of spurious authorities. At the same time nothing can tend more to lower a witness in the opinion of the court and jury, or diminish the value of his evidence, than the manifestation of a disposition to deal with his examiner as if he were a personal enemy, to evade the questions put, or to answer them with flippancy or anger. All such exhibitions invariably end in the discomfiture of the witness. It has been suggested that medical men on these occasions might take a lesson from lawyers, and observe how little they allow forensic differences, which they put on with their professional costume, to influence them in their intercourse with each other or with an adverse judge or jury.

Medical men have complained, and on many occasions justly, of the *license of counsel*. On this subject it may be well to consider what has been said by one of the highest authorities, the late Chief Justice Erle: "The law trusts the advocate with a privilege in respect to the liberty of speech which is in practice bounded only by his own sense of duty; and he may have to speak upon subjects concerning the deepest interests of social life, and the innermost feelings of the soul. The law also trusts him with a power of insisting upon answers to the most painful questioning, and this power again is in practice only controlled by his own view of the interests of truth." (Judgment in *Kennedy v. Broun*, 1862.) The late Lord Westbury described an advocate as one to whom all things are permitted, and by whom all things are proclaimed. Another great authority said, on a public occasion, that the first duty of an advocate was to reckon everything subordinate to the interests of his clients. The Lord Chief Justice of England, Sir A. Cockburn, in repudiating this doctrine, declared that the arms which an advocate wields, he ought to use as a warrior, not as an assassin. He is bound to uphold the interests of his client *per fas*, but not *per nefas*. He may use his best exertions, and employ all his knowledge, skill and experience to obtain the acquittal of his client, but in resorting to unfair means for this purpose, he ceases to be an advocate and becomes an accomplice. These excellent rules are frequently neglected in practice. Experience shows that almost unlimited powers of interrogation are entrusted to counsel by the law, and it is a serious question whether the unrestricted use

(which it has been justly remarked means only the frequent abuse) of these enormous powers, is necessary or even favorable to the administration of justice.

One of the most severe reprimands for this abuse came from the same learned judge in a case which was before him in 1857 ; it was addressed to a learned serjeant, now deceased, and was to this effect,—A question had been put throwing on the witness an imputation for which there was really no foundation. The learned judge then said : “ The freedom of question allowed to the bar was a public nuisance, and the barrister who made such an imputation ought to be prosecuted. If a question had relation to the truth, he was most anxious it should be put, but to cast haphazard imputations at the suggestion of a person (an attorney) who might have no scruples as to what he did, was a degree of mischief that made him wish that a party could be prosecuted. He begged leave to say that in his experience he had seen counsel so abuse their privilege, that he had cordially wished a power could be instituted that they might be prosecuted for a misdemeanor.” It is the general practice to say that the obnoxious questions are in the instructions, but a barrister can always exercise a power of putting or not putting a question which may be found there. By putting it he clearly adopts it, and frequently to the great damage of his own case. This is at present the only check upon the practice, for learned judges seldom interfere unless directly appealed to by the witness.

Some medical men lay themselves open to a severe cross-examination by not answering a question directly, or by giving an evasive answer, and there are others who come into the witness box with strongly biased views. In a case tried before Lord Coleridge in May, 1879, that learned judge, in commenting on conflicting scientific evidence, drew a marked distinction between a free professional witness and a witness by profession !

Medical men have claimed a *privilege* not to answer certain questions which have been put to them, on the ground that the matters have come to their knowledge through private and confidential communications with their patients. It is right to state at once that the law concedes no special privilege of this nature to members of the medical profession. No man is bound to reply to any question if the answer would tend in any way to incriminate himself—for no man is compelled to be a witness against himself. With this exception, all questions must be answered, provided they are relevant to the case, and their relevancy is a matter for the consideration of the learned judge who presides.

Sometimes a witness makes a frivolous objection and refuses to answer an ordinary question, thus bringing only ridicule upon himself. A skilled expert, at an important trial, was asked his age. Instead of answering so simple a question at once, he angrily appealed to the judge to know whether he was bound to give an answer on a matter which, as he said, could have nothing to do with the case. The judge informed him that unless he had some very strong reasons for concealing his age from the public, he had better state it ! I was once present at a trial for murder by poison, when, in the course of a cross-examination, counsel for the prisoner asked the medical witness what remedy or antidote he had

was clearly proved, from the effects of arsenic. The learned judge who tried this case said, "When the idea of poisoning struck them, they ought to have communicated their suspicion to the husband if they did not suspect him, and if they did suspect him, they ought to have gone before a magistrate, and not have gone on from the 8th to the 27th June seeing the woman murdered before their eyes." Sir R. Christison, in commenting upon this case, very properly takes exception to this advice, and there can be no doubt that any man acting upon it would expose himself to an action for slander. "Ideas" of poisoning often arise in cases of disease where the symptoms deviate a little from the ordinary course, but they are dismissed on further observation. If, in the absence of the means or knowledge of applying chemical tests, or of taking the opinion of others experienced in toxicology, a medical man charged the husband of a lady with secret poisoning, or went before a magistrate and charged him publicly, he would be acting with rashness, ruin his own practice and reputation, and be mulct in heavy damages for the irreparable injury done by a false accusation. Such a step should be taken upon something more than an idea or a suspicion. A prudent and conscientious man will always await the result of a chemical analysis before giving publicity to a suspicion which may after all turn out to be quite unfounded; and he will lose no time in obtaining this necessary confirmation or a removal of his doubts.

[Unquestionably, it is the first and paramount duty of the medical attendant to protect his patient, in a case of suspected poisoning; but he should be equally careful not to raise the suspicion against another—very possibly an innocent person—without the fullest and most unequivocal proofs. The practice of some medical "experts" in swearing to the presence of poison, not only when, in the language of Sir R. Christison, "the symptoms deviate a little from the ordinary course," but even when they are perfectly reconcilable with those of ordinary disease, cannot be too severely reprobated; especially when such "expert" opinions are maintained in non-fatal cases in the absence of all chemical tests on the food and drinks, and on the urine and other excreta of the patient.—R.]

When the suspicion is confirmed, there is some difference of opinion as to the course to be pursued. Sir R. Christison advises that when a medical man is satisfied of the fact of poisoning, he should communicate his conviction to the patient himself, and that he ought not to be deterred by the chance of injury to his patient, from making even so dreadful a disclosure. He will have thus taken the surest preparative step to prevent a repetition of the poisoning. Whether this communication be made to the patient or not, the proper course will be to place the matter immediately in the hands of a magistrate for investigation. Some years since I was consulted in a case of supposed slow poisoning. The symptoms suffered by a lady, taken as a whole, were not reconcilable with any disease. The medical gentleman had an "idea" that poison might possibly be the cause, but before acting upon this idea he sent to me a portion of urine for examination. Antimony was found in it, and the cause of the symptoms was at once explained. He communicated the result of the analysis to the members of the family, and the

symptoms of poisoning ceased from that time! The error committed by medical men is on these occasions, not in claiming a privilege of concealment, but in allowing a doubt upon so serious a question to remain in their minds for days or weeks.

This question was again brought into prominence at the trial of *Dr. Pritchard* at Edinburgh (July, 1865), on the charge of poisoning his wife with antimony. One of the medical witnesses, who saw the deceased a fortnight before her death and at other times, stated in his evidence at the trial that he suspected she was suffering from the effects of antimony when he first saw her, but it seems that there the matter was allowed to remain. No one was accused, but no step was taken to prevent the continuance of the poisoning, the suspicion of which turned out to be well founded. The Lord Justice Clerk, who tried this case, is reported to have said that no notions of medical etiquette should be permitted to interfere with those higher duties which every right-minded man owes to his neighbor, and which are to be expected in a tenfold degree from every medical man, because his life is solemnly devoted to the preservation of life and the prevention of its destruction.

Examination-in-chief.—The ordinary course of proceeding in a criminal case is thus concisely stated by Mr. Justice Stephen (“Criminal Law of England,” pp. 168, 282). After opening the case, the counsel for the Crown calls the witnesses, and examines them according to the rules of evidence—that is, he brings out, by questions *which do not suggest their answers*, the facts relevant to the issue to be tried which are within his personal knowledge. Those questions which do suggest the answers, are called “leading” questions. With one exception it is not the practice to allow these to be put in this part of the examination. The exception is: “When the judge is satisfied, either by a witness’s demeanor, or by contradictions between the evidence and the depositions, that he is trying to keep back the truth and favor the prisoner, he may, in his discretion, allow the counsel for the Crown to ask leading questions, and, as the phrase is, to treat the witness as hostile.” When the examination-in-chief is closed, the next step is the cross-examination.

Cross-examination.—In this, the second stage, the counsel for the prisoner extracts from the medical witness, by questions *which may suggest the answers in the strongest form*, any facts which may appear to be favorable to his client, and which he believes to be within the witness’s knowledge. Leading questions are not only allowable in this part of the examination, but, according to good authority, a counsel for the defence can hardly lead to much. The theory of the law is that the witness is unfavorable to the prisoner, and has come to bear evidence against him. The more he has shown himself by conduct or conversation a partisan in the case, the more severely will he be treated. Anything which he may have said in the hearing of others, or published in journals, or even written in private letters (if the contents transpire) in reference to the case or the guilt of the prisoner, is now brought to light, although he may have supposed that what he did say was in perfect confidence. It is at this stage of the case that any exaggerations which may have been most favorably received by the counsel for the prosecution are reduced to their true proportions. Any bias by which the mind of

a witness may have been influenced, or any imperfection or confusion of memory as to facts, is here brought out. (Stephen, p. 177.) It is in this part of his examination that the witness will be closely questioned as to his qualifications, the time during which he has been engaged in practice, the accuracy of his judgment, his general professional knowledge, and his special experience in reference to the matter in issue, the number of cases he has seen, etc. Straightforward answers should be given to all questions. No harm can be done to the witness by the answers unless they are given evasively, since it is not to be supposed that the witness wishes to represent himself differently from what he is. If he does make the attempt, he will assuredly fail.

The most striking distinction between the examination-in-chief and cross-examination is in reference to leading questions. It rests upon the assumption that there is a danger that a witness will say whatever is suggested to him by the one side, and conceal everything that is not extorted from him on the other. It need scarcely be observed that witnesses whose evidence is of little importance in the case, are rarely cross-examined. This is reserved in its most stringent form for those whose facts and opinions are likely to affect the fate of a prisoner in a criminal trial. In dealing with a skilled witness whose evidence may be of importance, the questions in cross-examination are usually put by the counsel for the prisoner with great caution, or the answers brought out may be more adverse to his own case than those elicited in the examination-in-chief.

Re-examination.—The cross-examination is usually followed by a re-examination on the part of the counsel for the crown, or of the counsel by whom the witness has been called. The object of this is to clear up or explain any portion of the evidence which may have been rendered obscure or doubtful by the cross-examination. It is sometimes unnecessary to put a question, and if the witness has given his evidence consistently and fairly, no questions may be asked. As a rule, the re-examination must be confined to those matters which have arisen out of the cross-examination. Any questions upon new subjects may render a further cross-examination on them necessary. In reference to *facts*, a medical witness must bear in mind that he should not allow his testimony to be influenced by the consequences which may follow from his statement of them, or their probable effect on any case which is under trial. In reference to *opinions*, their possible influence on the fate of a prisoner should inspire caution in forming them, but when once formed they should be honestly and candidly stated without regard to consequences. It will be well to remember, in reference to each stage of the examination, what a great medical authority has said: "To make a show and appear learned and ingenious in natural knowledge may flatter vanity. To know facts, to separate them from supposition, to arrange and connect them, to make them plain to ordinary capacities, and, above all, to point out their useful applications, should be the chief object of ambition." (William Hunter.)

Quotations from books.—It is a not unfrequent custom with counsel to refer to medical works during the examination of a witness. He is expected to have a fair knowledge of the writings of professional men on the subject

of inquiry. The authority is mentioned, the passage is quoted, and the witness may be then asked whether he agrees with the views of the author, or whether he differs, and if so, his reasons. In cases connected with medical treatment, the views of the profession are and have been so various, that a barrister would have no great difficulty in finding some book to oppose to the opinions of a witness. Standard works of recent dates are so well known to the profession that there are few medical men engaged in practice who are not well acquainted with, and able to explain the views of the writers, and how far they agree or conflict with his own. The witness must be on his guard that the question is fairly put, and that it is properly taken with the context, or he may unexpectedly find himself involved in a difficulty. On one occasion, I found that a learned gentleman stopped in his quotation at a comma, and on another occasion the quotation ended at a colon—the remainder of the sentence in each case materially weakening the inference which it was intended to draw with the apparent sanction of the witness.

When a quotation from a standard work is thus opposed to the evidence of a medical witness, he should take care by reference to the work itself to see that the passage is correctly quoted. A remarkable instance of the importance of this caution has been communicated to me by a former pupil. At the Swansea Lent Assizes 1869, an action was brought against a railway company for compensation for personal injury. Plaintiff was proved to have had pneumonia shortly after the accident, and the counsel for the company wished to show that the pneumonia had not arisen from any physical injury. In cross-examining the medical witness he asked, "Cannot pneumonia be produced by shock?" *Witness*: "I do not believe it to be possible." *Counsel*: "What! do you mean to say you do not believe what is asserted in fact by no less authority than Professor Taylor? Have you read Dr. Taylor's work on 'Medical Jurisprudence?'" *Witness*: "Yes." *Counsel*: "Have you seen the last edition?" *Witness*: "No." *Counsel*: "I have it here (turning over the leaves of a book), and a case is given of pneumonia caused by shock." (Witness in confusion.) It was subsequently discovered on referring to the work, that the case in question was one in which the lung had been wounded by a fractured rib. The cause of the pneumonia was thus sufficiently explained; it was proved to have been a result of physical injury, and not of shock! A reference at the time to the work which is quoted is always necessary, if any use is to be made of a quotation. Without suggesting that there is intentional misrepresentation to bear out a particular view of the case, a barrister, in dealing with the medical facts, may wholly misunderstand the author's views and statements, and in some instances wrongly assign to the author opinions which he has merely quoted from other authorities for comment or illustration.

Presence in court.—In England, medical and scientific witnesses, except under special circumstances, are allowed to be present in court and hear the whole of the evidence in the case. This is in some instances absolutely necessary if the court requires medical opinions, for unless the witnesses are fully acquainted with the facts they can give no opinions, and they can only become fully acquainted with the facts by being allowed to be present and hearing the evidence in court. If excluded,

the judge or counsel will be compelled to read to the witness notes of the evidence before an opinion can be given, and it may then appear that some small point which counsel did not think of importance is omitted; this if known to the witness might, however, materially affect his opinion. A failure of justice is likely to occur when medical witnesses are excluded, and it is generally when there is no defence, or a false defence, that the right of excluding them is exercised. The rule in Scotland is similar: medical and scientific witnesses are allowed to be in court during the trial.

The examination of the witnesses for the crown is followed by the defence of the prisoner, either in person or by his counsel, who acts throughout the part of an advocate, simply securing for his client every advantage the facts or the law may afford him. In other words, he sees that his client is strictly tried according to law, and not condemned contrary to law. A key to some of the difficulties which medical witnesses must be prepared to encounter will be found in the exposition given by Mr. Justice Stephen of the tacit rules which regulate the duties of counsel for the prosecution and defence:—"In practice it is universally admitted that the counsel for the prosecution is morally and professionally bound always to keep in sight the ultimate object—namely, the discovery of truth; whereas no such obligation is laid upon the prisoner and those who represent him, because it is too much to expect of human nature that they should discharge it, and it is better not to impose an obligation which is sure to be systematically violated. Both sides, on the other hand, are bound in the strongest way *not to do anything to propagate falsehood*. The counsel for the crown is bound not to suppress any fact within his knowledge favorable to the prisoner; and, on the other hand, the counsel for the prisoner is bound not to bring to light facts within his knowledge unfavorable to the prisoner." "The counsel for the crown may not use arguments to prove the guilt of the prisoner which he does not himself believe to be just, and he is bound to warn the jury of objections which may diminish the weight of his arguments; in short, as far as regards the evidence which he brings forward, his speech should as much as possible resemble the summing up of the judge. He should contend not for the success of his cause at all events, but for full recognition by the judge and jury of that side of the truth which makes in favor of it. On the other hand, the counsel for the prisoner may use arguments which he *does not believe to be just*. It is the business of the jury, after hearing the judge, to say whether they are or are not just." (Op. cit., pp. 160 and 168.) The last remark shows what appears to be a serious defect in the administration of the criminal law. While in a case of misdemeanor, a prisoner may be tried by a special jury, in a case of felony, involving an analysis of important questions of medical science in reference to murder or manslaughter, the trial takes place before a common and comparatively ignorant jury. Such a jury is hardly in a position to cope with an ingenious counsel, who has it in his power to misrepresent and distort medical facts and opinions in any manner that he pleases. The defences made are frequently such as no barrister would venture to place before a jury of educated men. These "powerful" or "forcible" addresses, as they are termed by the press,

full of burning eloquence and impassioned logic, have frequently withdrawn the attention of the jury from the real facts, and have procured verdicts of acquittal contrary to the evidence and all the medical circumstances of the case.

Another observation made by Mr. Justice Stephen more nearly concerns the medical witness: "There are many obligations which affect each side equally. Neither is at liberty to attempt to browbeat, intimidate, or confuse a witness, although they may expose any real confusion which exists in his mind, or test, by the strictest cross-examination, the accuracy of his statements. Neither is at liberty wilfully to misunderstand a witness, or *in his address to the jury* to *misstate* the effect of what he has said, either by distortion or suppression. The neglect or observation of these and other rules of the same kind practically establishes a wide distinction, and one which is easily recognized, between those who exercise a noble profession and those who disgrace it." (Op. cit., p. 168.)

The treatment of a medical witness, in passing through the ordeal of an examination at a criminal trial, will depend, therefore, very much upon the class of counsel who is opposed to him. Assuming that he is properly prepared for the discharge of his duties, and that the questions put to him are answered fairly and truly according to his knowledge and experience, without exaggeration or concealment, he has no reason to fear any attempt at intimidation. Barristers, for the most part, know that by this line of conduct, they lose more with the jury than they gain by the attempt to confuse the witness; and as their ultimate and sole object is a favorable verdict, they will generally avoid conduct which must necessarily place this verdict in jeopardy.

The normal barrister, we are told, is not at liberty, in his address to the jury, to misrepresent, either by distortion or suppression, the medical facts or opinions given in a case. According to my experience, however, misrepresentation is a not unfrequent practice, and one of which medical witnesses have very strong reason to complain. Whether such misstatements are wilful or not it may be difficult to determine, but their effect on the jury is well known to those who employ them, and they frequently escape the observation of the counsel on the other side, and even of the learned judge, unless he is well versed in medical subjects. It is also worthy of remark, that if a misstatement is thus made, it is, by a remarkable coincidence, always in favor of the view of the counsel who makes it, when a proper examination of his notes would, in general, show that he was wrong.

Then, as to the question of intimidation, this is sometimes carried very far. On a trial for murder by poisoning, I have heard a respectable country practitioner, who had given his evidence for the crown in a fair and proper manner, thus addressed in cross-examination by a learned counsel now deceased:—"On your oath, sir, and in the face of the whole profession, will you venture to persist in that statement?" etc. Again, the intimidating modes of address—"Do you mean to swear?" "Will you pledge your professional character?" etc., intermingled with the admonitions, "Pray be careful," "Be cautious," etc.—of course suggest to the witness that his examiner already regards him as perjured, and

that, however truly he may state the facts within his knowledge, he will not be believed.

A public writer, in commenting on this subject, says, "But the hardest and most unfair part of the system (of cross-examination) is when witnesses have to bear a loud and insulting tone or gesture without remonstrance or retaliation. A counsel may very plainly imply that a respectable witness is a person of doubtful character, and not to be believed on his oath, or that he is ignorant, and a bungler in his profession; but if the witness retorts that the barrister's eloquence and sympathies are hired, or if he gives vent to any other words of retaliation in his natural indignation, the court is against him." At the trial of Kelly for the murder of Police Constable Talbot (*Reg. v. Kelly*, Dublin Commission Court, November, 1871), Mr. Tuffnell, a surgeon of repute, and formerly Professor of Surgery, was summoned as a witness for the prosecution. Having deposed to the nature of the wounds, and that the deceased had died from the effects, he was subjected to the usual ordeal of a cross-examination, but in a somewhat unusual form. Counsel for prisoner having begun by addressing him in a loud and offensive tone, he turned to the Chief Baron, and said, "My Lord, I am very excitable, and if this gentleman has a right to roar at me, I consider that I have a right to roar too." The court expressed a hope that it would not be necessary for him to roar, and intimated, after a short trial of vocal strength between the two opponents, that counsel's manner to the witness was not what it ought to be. Counsel disclaimed any intention of being offensive, but claimed the liberty which is usually conceded in cases of importance. Whatever may be the importance of a case to the prisoner, nothing can justify the putting of questions in a loud and insulting tone to a skilled professional witness. The very mild rebuke administered to counsel on this occasion was not likely to produce much effect, and accordingly this trial presents, in a concentrated form, all the defects of our method of getting at truth by cross-examination. The result is seen in the unsatisfactory nature of the verdict, which was against the medical and general evidence in the case.

These results may be perhaps explained by assuming that criminal cases fall more into the hands of the second class of barristers, namely, of those who disgrace a noble profession. But it is a widely spread opinion in the medical profession, that this style of examining educated men, who are perhaps compelled most unwillingly to appear on a subpoena to testify to facts, is certainly not adapted to elicit the truth, but rather to favor the escape of criminals and give impunity to crime.

It may be fairly admitted that the man who puts himself forward as a witness, and attempts to elucidate what he only succeeds in rendering more obscure, should receive no favor at the hands of the bar. Dr. Ellwell, a member of the legal as well as of the medical profession, observes that—"No witness is ever compelled to appear and testify to what *he does not know*. He may be compelled to attend in court in obedience to a subpoena, but if he attempts to testify upon a subject requiring *opinions* upon which he has no well-settled or well-defined ideas, it is his own fault, and he alone is to blame; for no one but himself can know so well as he, until he has exposed himself, how unfit he is for the occa-

sion.” (Medico-legal Treatise on “Malpractice and Medical Evidence,” by J. J. Elwell, M.D., Member of the Cleveland Bar, New York, 1860, p. 302.) But let us take the case of a practitioner who, in a country district, has gone through twenty years of practice with honor and credit in his neighborhood, and who is suddenly called to a case in which a man is found dead from a wound in his throat. Under the Medical Witnesses’ Act he is compelled to make an examination of the body for a coroner’s inquest. At a great loss of time, and for no adequate remuneration, he attends the inquest, and gives his evidence ; he is bound over, *nolens volens*, to appear for the first time as a witness at a criminal trial, and to testify, 1st, to the throat being cut, and 2dly, to give his opinion to the court on the cause of death, and whether the wound was inflicted by the deceased on himself, or by another person. A medical man who limited himself to the statement of the bare fact that the deceased’s throat was cut, need not appear at all, for this evidence might be supplied by a constable or policeman ; but the law presumes from his profession, that the medical man made a proper examination of the wound, with a view to determine, to the best of his ability, whether it was the cause of death and whether it was or was not self-inflicted. It is difficult to understand how a medical man, although before this occurrence he may never have seen a case of cut-throat, could excuse himself from giving an answer to these questions, both of which involve purely matters of *opinion*. If he excused himself altogether from giving answers, there would be a failure of justice, and no conviction for such a common form of murder could ever take place. If, on the other hand, he answers these questions to the best of his ability, he may reasonably complain that while thus compelled to appear as a witness, to testify to what he does know, his evidence should, by rules of law, be made the subject of abuse and ridicule before his neighbors, when he expresses his *opinion* from the facts ; and that the counsel who examines him, legally possesses an unlimited power of misrepresenting his views. A medical man is certainly not benefited by being described as an ignoramus or a blunderer in his profession, whom no one ought to trust. The truth is, in medical evidence facts and opinions cannot be separated, and if medical practitioners were restricted in their evidence only to those facts which they had observed in a case in which no other professional man saw the person living or dead, it is difficult to understand how crime could be detected and punished. These remarks of course do not apply to cases in which the opinions of medical experts can be taken. Here it would be desirable that one who has not had experience on the subject should avoid giving any opinion ; he might simply state the facts, and decline from want of experience to give an opinion on the conclusions to which they lead. In pursuing any other course, he will find that the whole weight of the cross-examination will fall upon him.

There are some remarks on this subject made by Dr. Elwell, which those who are compelled to attend as witnesses in a court of law, will do well to bear in mind : “However anxious an incompetent witness may be to appear learned, and however hard he may labor to show it, he will ever find it a difficult business to make the court and counsel believe that he is really so. To appear really learned he must be able to

make the subject on which he gives an opinion *clear*, and to give *satisfactory reasons* for this opinion. He must be not only a thinker, but must satisfy others that he is master of the subject. Take almost any one of the important scientific questions upon which a professional witness is called to pass an opinion, and unless he has *looked at the subject before with a purpose to understand it*—comprehending its extent, weight, and relations—he will find it to have suddenly assumed an importance he has not suspected, just at the time when the discovery will add to his confusion. It is better to make this discovery in the quiet stillness and security of solitude, than under the eye of a judge and the severe scrutiny of counsel. A man, whether learned or not—whether in court or out of court—will talk clearly upon a subject he well understands, whether it is scientific or otherwise, but *unless it is clear in his own mind his account of it will be confused and unsatisfactory.*” (Op. cit., p. 303.) This is undoubtedly the test to which every man should rigorously submit himself before entering the witness box. The case should be viewed in all possible aspects, and if an opinion has been formed, it should be dealt with and criticized as if it were that of an adversary. As in controversy, a disputant should place himself as much as possible in the position of his antagonist, and see his question from his point of view. In this kind of self-examination it may be well to remember two points—1st, that there is no opinion so certain as that the human mind, if left to itself, will not infallibly raise a difference of opinion upon it; and 2dly, that a man is never so near an error as when he claims a complete immunity from error.

There is a difference between evidence and testimony. A medical witness sometimes gives much in the form of testimony which amounts to very little as evidence. When he does not attend to the questions, he testifies to a variety of subjects which have no bearing on the case, and do not constitute evidence. The decision on what is and what is not evidence lies with the judge.

Rules for the delivery of Evidence.—There are a few rules bearing upon medical evidence which, if observed, may save the witness from interruption or reproof and place him in a favorable position with the court:—

1. The questions put on either side should receive *direct* answers, and the manner of the witness should not be perceptibly different, whether he is replying to a question put by the counsel for the prosecution or for the defence. For reasons elsewhere assigned (p. 47), most of the questions put by counsel in cross-examination will admit of an answer “yes” or “no.” If, from the ingenious or casuistical mode in which the question is framed, the witness should feel that the simple affirmative or negative might mislead the court, then, after giving the answer, he can appeal to the judge to allow him to qualify it, or add to it any matter within *his own knowledge*, and which is at the same time relevant to the case. The witness must remember that he takes an oath to state the truth, *the whole truth*, and nothing but the truth. On the other hand, while the counsel for the defence is bound not to introduce falsehood, his object is *not* the discovery or the development of truth. Unless the witness is on his guard, he may find, when the learned counsel who has cross-examined

him addresses the jury, that his affirmatives and negatives may be worked into a shape representing the reverse of what he intended.

Some counsel adopt the ingenious plan of compressing two or three questions into one, or they submit a series of questions, more than one of which may contain two opposite alternatives, and then ask for a plain answer "yes" or "no" to both of them together. A witness may unthinkingly answer that question which has most fixed his attention. The same answer may not be strictly applicable to all, but it may be found, when too late, that it is made so in the defence. Under these circumstances he should ask for a severance of the questions and give separate replies. Direct answers are necessary, because it is only by them that the case can be brought clearly before the court and jury in all its details. Medical witnesses sometimes forget this, and fall into answers to questions floating in their own minds, or which they think are likely to be put to them. They are also sometimes disposed to anticipate many questions by one general answer. This simply creates confusion, and the witness will be told by counsel to keep to the question, and that he is coming to the other matters presently. Care should be taken by a medical witness not to argue with the learned counsel. Argument is not evidence, and the entering into it disturbs the order of the proceedings. Arguments between counsel and witnesses, and even between medical witnesses themselves, are freely allowed in the French courts, but in England such a practice is not recognized. The mode in which questions are put by counsel in cross-examination sometimes tends to the introduction of argument, but the witness should avoid the temptation to enter into it. What he says under such circumstances is not evidence, except in the form of answers to questions, and he is there only for the purpose of stating what is relevant to the case.

2. The replies should be concise, distinct and audible, and, except where explanation may be necessary, they should be confined strictly to the terms of the questions. The learned judge who tries the case, generally takes full notes of the medical evidence—hence the necessity for a slow and distinct delivery of the evidence. Some witnesses have a singular habit of not answering the question which is asked, but one which is not asked. Others give an answer in such a voluble form, in the shape of a small speech or lecture, that there is great difficulty in reducing it to its proper proportions. A witness who is so profuse of information, generally supplies abundant matter for a long and troublesome cross-examination. It has been a question whether a witness should volunteer evidence, assuming that the examination-in-chief and cross-examination have failed to bring out all that he knows of the case. If that which he has to state is some matter of fact within his own knowledge, or an opinion based on facts within his knowledge, he will be allowed, on application to the judge, to make the statement, in spite of the efforts of counsel on either side to shut it out.

It is scarcely necessary to observe, that the language in which the answers are returned should neither be technical nor metaphorical. Counsel who are unacquainted with medical terms frequently misapply them, or use them in a wrong sense. There are few barristers who are aware that the term "symptom" is confined to the living body, and

“appearance” to the dead; and the witness may thus find himself questioned on the “appearances” when he first saw the patient, or the “symptoms” which he observed on the post-mortem examination of the stomach and bowels. On a trial for murder, in which one of the questions at issue was whether dysentery or poison was the cause of death, the learned counsel puzzled one of the medical witnesses by asking him whether during his attendance he found any traces of “*dysuria*” in the feces! There is no doubt he intended a state of the feces like that met with in dysentery, but the professional term employed by him signified a “difficulty in passing urine!” A judicious witness will avoid anything like a triumph over his examiner under such circumstances, and simply put him right.

3. Answers to questions should be neither ambiguous, undecided, nor evasive. An ambiguous answer necessarily leaves the witness’s meaning doubtful, and calls for an explanation. An undecided answer—indicated by the words “I believe,” or “I think,” or “It might be,” is not sufficient for evidence. Did the wound cause death? Was death caused by loss of blood or poison? If, by a proper consideration of all the medical facts, the witness has come to a conclusion on the subject, his answer should be expressed in plain and decided language, either in the affirmative or negative. A man who has formed no conclusion is not in a position to give evidence. No opinion should be given for which the witness is not prepared to assign reasons, and, except by permission of the court, no medical opinion should be expressed on facts or circumstances observed by others. A hesitating witness will be met with the question, Have you any doubt about it? or, Was it so or not?—to which a reply in the affirmative or negative must be given. If the witness fairly entertains doubts about the matter at issue, it is his duty to express them, and not allow them to be extorted from him piecemeal by a series of questions. Chemical witnesses have occasionally certified to the discovery of “imperceptible,” “unmistakable,” or “undoubted” traces of poison in the liver, etc. Such terms naturally convey to the shrewd mind of an examiner that the witness has some lurking doubt or suspicion of mistake in his mind, for that of which we are sure requires no such terms to express our meaning. If poison has been discovered, the statement of the fact is sufficient.

4. The replies should be made in simple language, free from technicality. Some remarks have been elsewhere made in reference to the use of technical terms in drawing up medico-legal reports (p. 29). If medical men could be made aware of the ridicule which they thus bring on their evidence, otherwise good, they would at once strive to dispense with such language. A witness is perhaps unconsciously led to speak as if he were addressing a medical debating club, instead of plain men like the members of a common jury, who are wholly ignorant of the meaning of medical terms, and barristers who are but imperfectly acquainted with them. There are few Assizes which do not afford many illustrations of the injury done to scientific evidence and the clear understanding of a case, by the technical language in which it is given. The court may be told that the “*integuments* were *reflected* from the thorax, and

the *costal* cartilages laid bare, when a wound was found which had penetrated through the anterior *mediastinum*," and had involved the arch of the aorta, etc. A simple cut in the skin is described as "an incision in the integuments." In a case of alleged child-murder, a medical witness being asked for a plain opinion of the cause of death, said that it was owing "to *atelectasis* and a general engorgement of the pulmonary tissue." On a trial for an assault which took place at the Assizes, some years since, a surgeon, in giving his evidence, informed the court that on examining the prosecutor, he found him suffering from a severe contusion of the integuments under the left orbit, with great extravasation of blood and ecchymosis in the surrounding cellular tissue, which was in a tumefied state. There was also considerable abrasion of the cuticle. "*Judge*: You mean, I suppose, that the man had a bad black eye? *Witness*: Yes. *Judge*: Then why not say so at once?" It would be easy to multiply examples of this kind.

This is not science but pedantry, and if such language is employed by a witness with a view of impressing the court with some idea of his learning, it wholly fails of its effect. Barristers and reporters put down their pens in despair, and the time of the court is wasted until the witness has condescended to translate his ideas into ordinary language. Lord Hatherley well observes that "a scientific witness in giving his evidence should avoid as much as possible the use of technical scientific language, if the case is before a jury. This is especially desirable when the evidence is medical, for really many technical words in medicine seem to be invented to cover ignorance. But be this as it may, a witness is always suspected of affectation, and the court and jury are but little instructed, when a vast amount of learned phraseology is poured forth instead of a clear statement of the witness's opinion." Lord Hatherley has also commented on the obstinacy with which some scientific witnesses will adhere to an opinion once expressed in spite of good reasons brought forward by counsel in cross-examination, which should induce the witness to change or modify it. This bias in evidence, which is generally obvious to all in court excepting the witness, drew on one occasion from a learned judge the remark that a distinction must be made between professional witnesses and witnesses by profession.

5. In giving evidence of *opinion* a medical witness must take care not to base it on any statements made by others, or on circumstances which may have come to his knowledge by public rumor. Again, his evidence should be confined only to subjects properly within the range of medical science, and on which, as a professional man, he is competent to speak. In a trial for murder by wounding, in which the identity of the prisoner was in question, a medical man stated that he compared certain footmarks with the boots taken from the prisoner, and he found that they corresponded. A comparison had also been made, but not at the same time, by a police-officer, more accustomed to matters of this kind. On cross-examination, there was such a want of agreement between the surgeon and the constable, respecting the number of nails in the boots and the number indicated by the footprints, that no reliance could be placed on this portion of the evidence. In reference to this discrepancy, the learned judge remarked that a medical man should confine

himself to matters belonging to his own profession, and not take upon himself the duties of a police-constable. There are some points in reference to gunshot wounds which can be better explained by a gun or shot manufacturer than by a medical witness.—*Cuique in sua arte credendum.*

Exaggerated language should be avoided. The observations elsewhere made (page 29), in reference to medico-legal reports, apply equally to the delivery of evidence in courts of law. The use of exaggerated language often leads to an apparent conflict in medical evidence. Thus one witness may speak of patches of ulceration in the intestines, while another may describe the same condition as “extensive ulceration.” On a trial for murder by poisoning, a witness, when asked by the court as to his experience of the effects of the poison on man and animals, said that he had seen “some dozens of cases.” These “dozens,” on cross-examination as to time, place, and circumstances, were reduced to the modest proportion of about six to eight cases. Such a mode of describing facts seriously affects the credit of a witness. Its tendency is to throw a doubt upon the whole of his evidence.

The statements made by a medical witness on a trial at the Assizes should be consistent with the depositions previously taken before a magistrate or a coroner. Any deviation is closely scrutinized, and, unless satisfactorily explained, may involve the witness in some trouble. In *Reg. v. Gibson* (Winchester Summer Assizes, 1877), a trial for felonious wounding, the medical witness deposed that the wound on prosecutrix had been produced by some blunt instrument like a man’s fist, *not* by the blade of a knife. In his deposition before the magistrates he had described it as a severe wound, very deep, and such as might have been produced by *a knife* found on the prisoner. He admitted that he had changed his opinion. He was ordered by the judge to leave the court.

CHAPTER III.

CAUSES OF DEATH.—SUDDEN DEATH.—SYNCOPE, ASPHYXIA, COMA.—SIGNS OR INDICATIONS OF DEATH.—CESSATION OF CIRCULATION AND RESPIRATION.—COOLING OF THE BODY.—CADAVERIC RIGIDITY.—PUTREFACTION.—CHANGES PRODUCED IN THE BODY.—PUTREFACTION MISTAKEN FOR GANGRENE.—CADAVERIC LIVIDITY.—ADIPOCERE.

MEDICAL Jurisprudence takes cognizance of all violent causes of death, and is only indirectly involved in those cases of natural death which simulate the effects of violence. Thus all causes which operate to produce death suddenly, as by *syncope*, *asphyxia*, or *coma*, especially demand the attention of a medical jurist. These may be either natural or violent; and the distinction between them is of importance, since the guilt or innocence of a party charged with crime may depend on a correct determination of the cause.

The continuance of life depends upon the proper and regulated action

of the heart, the lungs, and the brain; and the interdependence of these organs is such, that the arrest of the functions of one of them is speedily followed by the arrest of the functions of the others. Hence these three organs have been called the tripod of life. When the suspension of the motions of the heart is the primary cause of death, the person is said to die by syncope. The term asphyxia is applied to death which begins by the lungs; and coma to that which arises from a primary disturbance of the functions of the brain.

Syncope (*συνκόπτω*, signifying to strike down).—In order that the action of the heart should be maintained, it is necessary, first, that the blood supplied to it should be in sufficient *quantity*, and secondly, that this blood should be of proper *quality*. In death from hemorrhage we have an instance of deficiency, and in death from certain poisons as well as diseases, an illustration of defect of blood. In ordinary syncope (fainting or swooning) there is simply a deficiency in the quantity of blood which passes through the heart, although there is no actual loss of this fluid from the circulation. Certain diseases which affect the muscular structure of the heart, as well as its membranous valves and blood-vessels, may also lead to a sudden arrest of its functions. These morbid conditions produce a mechanical impediment to the motions of the organ by which the blood is propelled, and death by syncope is the necessary result. When death takes place by the heart, the right and left cavities of this organ are found to contain blood in the normal proportion in which that fluid is ordinarily circulated. This retention of blood in these cavities arises from the sudden stoppage of the heart's contractions. Blood is found in the large veins (*venæ cavæ*), as well as in the arterial trunks. There is no congestion or accumulation of blood in the lungs or the brain.

Asphyxia (*ἀ* priv. and *σφύξις* pulse, signifying pulselessness).—This state is induced by any cause which arrests the function of respiration. The term *apnœa* (from *ἀ* priv. and *πνέω* I respire) is more appropriate for the state of syncope might equally be called asphyxia. The various forms of death by suffocation, as in the obstruction of the air-passages from mechanical causes, in drowning, hanging, and strangulation, illustrate illustrations of death commencing by the lungs, or asphyxia. The effect of cutting off air from the lungs is that the blood is not aerated, and is therefore circulated in a state unfitted to support the nutrition of the heart and brain, without which life cannot continue beyond a few minutes. It is necessarily distributed with the impurities derived from the waste of tissue, and thus acts as a poison to all the organs capable of sustaining nerve-force or muscular irritability. The obstruction of the capillary vessels of the lungs, produces a languid circulation, and by its circulation through the muscular structure of the heart and brain, causes insensibility by its distribution through the nervous system. The brain, which then ceases to supply the proper stimulus to the heart. The lungs are essential to the circulation by purifying the blood. Death from asphyxia may be therefore regarded as death from the want of oxygen. The observations of the late Sir B. Brodie and others have clearly proved that in spite of the arrest of respiration the heart will continue to act and the circulation will continue for some time.

two or three minutes or longer after breathing has entirely ceased. This has been proved by hanging or suffocating an animal, and observing the condition of the heart during the stage of insensibility. As the action of this organ continues after the animal has ceased to breathe, life is not actually extinct; and under favorable circumstances, it may be restored, if no injury be done to the structure of the lungs, so long as this action continues. Supposing that the suspension of respiration is complete, the action of the heart gradually slackens and finally stops. It is at this period of the complete arrest of the motions of the heart that asphyxia passes into death. Apnoea is determined by the time at which breathing is completely arrested. The circulation of the unaërated blood through the brain, appears to annihilate sensibility, so that no consciousness or feeling exists; the person is, to all appearance, dead. There are many diseases which operate fatally by arresting the functions of the lungs, and these may be regarded as furnishing the natural causes of asphyxia. The violent causes, including not only the ordinary modes of suffocation, but the effects of certain poisons, are not difficult to appreciate, provided a true history of the case can be obtained.

In death by the lungs, as the circulation of the blood is primarily arrested in these organs, the pulmonary artery, the right cavities of the heart and the venæ cavæ are found gorged with blood. The pulmonary veins, the left cavities of the heart and the aorta, are either empty or contain but little blood. In certain cases of asphyxia, the right cavities of the heart, as well as the left, have been found empty. When the access of air to the lungs is suddenly and completely cut off, the circulation of the blood is very speedily arrested; but supposing the occlusion of the air-passages to be partial or gradual, the circulation of the blood may continue for a time, and thus cause congestion of certain organs. Hence the appearances in asphyxia differ greatly. A mixed condition under the name of syncopal asphyxia has been described by some pathologists. In this, the cavities of the heart are found empty.

Coma (from τὸ κῶμα, a deep sleep).—In addition to a due supply of properly aërated blood, the brain requires for the exercise of its functions a proper quantity of blood, so that either by the sudden withdrawal of this fluid, or by the distribution of impure blood, these are arrested. A person thus affected falls into a state of complete insensibility (coma), so that it is impossible to rouse him. The functions of the heart and lungs are not suddenly arrested under these circumstances. They appear to be less dependent on the brain than the brain is upon them; but this is rather a question of degree. A due supply of nerve-force is required for the action of the muscles, whether of the heart or of the chest; and when this is withdrawn, the heart ceases to pulsate, and the respiratory muscles cease to act; circulation and respiration are thus arrested by the absence of innervation. This is sometimes described as death by paralysis of the heart and lungs. The blood is neither aërated nor circulated. Sudden death from apoplexy is an illustration of death by the brain. Coma may also be a result of the introduction of certain poisons into the blood, and of fracture of the skull leading to compression of the brain or destruction of its substance. In death by the brain, the appearances observed consist chiefly in a congested state of the cerc-

bral membranes and substance of the brain. As, before death, the breathing is affected, the lungs are congested and blood accumulates in the cavities of the heart, more on the right than on the left side. The appearances described as characteristic of the different modes of death by the heart, lungs, and brain, are liable to variation by reason of the intimate relations of these organs. Thus, there may be a mixed condition of syncope and asphyxia, or of asphyxia with cerebral congestion.

With regard to the interruption of the functions of the brain as a result of pressure by the effusion of blood or serum, it is to be observed that a very small quantity effused at the base or in the substance of the medulla oblongata, is sufficient to cause death; while generally speaking a large quantity is required to be effused in the membranes, ventricles, or substance of the brain, in order to produce a fatal result. [In some cases of violent death by fracture of the skull, the supervention of coma is very gradual, in consequence of the slow effusion of blood into the brain from the ruptured vessel.—R.] In cases of chronic hydrocephalus, in which the brain has resisted the pressure of a large accumulation of serum for many years, a slight and sudden increase in the quantity at any period of life may lead to coma and death by apoplexy. This condition may be mistaken for narcotic poisoning.

All causes of death, whether from disease or violence, are referable to an effect produced primarily on the heart, the lungs, or the brain; but, as it has been elsewhere stated, death does not really take place until the action of the heart has entirely ceased. The arrest of the circulation produces an immediate impression upon the functions of the brain and lungs; while the lungs and brain are affected and can only affect each other indirectly through the medium of the circulation; hence, systemic death, or death of the body, is resolvable into death by syncope or a failure of the action of the heart, and this depends in all cases either upon defect or deficiency of blood.

The natural causes of *sudden death* may be generally traced to some injury or impediment to the action of the heart, lungs, or brain. It would be foreign to the objects of this manual to give a description of them. The violent causes are those which demand the especial attention of a medical jurist; they will be considered hereafter. In its relation to medicine and medical jurisprudence the subject of sudden death has been most fully treated by Herrich and Kopp (*“Der plötzliche Tod aus inneren Ursachen,”* Regensburg, 1848); as well as by M. Devergie (*“Ann. d’Hyg.,”* 1838, vol. 2, p. 145). To these works I must refer the reader for further information on the causes, as well as on the appearances met with in the bodies of persons dying suddenly from natural causes.

The *violent* causes of death, whether sudden or protracted, which chiefly require the skill of a medical jurist for their elucidation, are poisoning, wounds, and personal injuries, such as burns and scalds, as well as those forms of death which commence by the lungs, including drowning, hanging, strangulation, and suffocation. In nearly all cases, the body of the deceased is produced, and a medical opinion can be based upon a careful examination.

Signs or indications of death.—The verification of death is occasionally a duty thrown on the medical jurist. Certain signs or indications have been pointed out as proving that death is real, and not apparent. These are taken in the order of their importance.

1. *The cessation of circulation and respiration.*—The heart is considered to be the organ in which life begins and ends—the *primum vivens* and *ultimum moriens*—the first to live and the last to die. The proof of death is, therefore, the proof of the cessation of the heart's action for a certain person. The more visible indication of death is the cessation of breathing, and, in the opinion of the late Sir B. Brodie, the entire cessation of breathing alone may be regarded as a decisive test of the extinction of life. The movements of respiration cannot be overlooked by any one who does not choose to overlook them, and the heart never continues to act for more than four or five minutes after respiration has ceased. The proofs of the continued action of this organ are, however, less obvious to the unskilled observer than the movements of the chest; hence the visible cessation of these movements, *i. e.*, of breathing, for a period of five minutes furnishes a certain proof that the person is really dead. But the skilled observer would apply the test of auscultation, and before giving an opinion would satisfy himself of the permanent cessation of the heart's action. It is impossible to admit that the heart can remain for even half an hour in a state of inaction in a human being, and then spontaneously recover its activity.

[The case of Colonel Townshend, mentioned by Dr. Cheyne, is an apparent exception to this rule. He possessed the remarkable power of a seeming voluntary death, *i. e.*, of suspending the action of the heart and lungs for the period of half an hour. His condition most probably resembled that of an animal in a state of hybernation, during which the heart-beats are reduced to an extremely low figure; and it appears to be actually dead; but unquestionably the functions of both heart and lungs are going on, though in a very feeble degree.—R.]

The entire suspension of the circulation may be demonstrated by a simple experiment. A ligature tied tightly round the last joint of a finger will cause the part beyond to swell, as a result of obstructed circulation, if the person is living; but if dead, there will be no appearance of this kind; the parts will remain unchanged.

2. *Cooling of the body.*—The average temperature of the interior of the *living* body in health, varies from 98° to 106° , and this it retains so long as life continues, whether the temperature of the air is below zero or above 140° . It is liable to be increased in some diseases, and to be diminished in others. In a case of typhoid fever, the blood was found to have a temperature of 113° . When life is extinguished, the body gradually loses the heat which it possessed at the moment of death, just like so much inert organic matter artificially raised to the same temperature, and it cools down to the temperature of the air to which it is exposed. The time usually assigned for the cooling of the dead human body, is from *fifteen to twenty hours*, but it varies according to the condition of the body at the time of death, the mode of death, and the circumstances under which it has been placed. Thus, if exposed naked to a cold atmosphere, the cooling is very rapid. If the body is well covered,

the cooling takes place slowly. When death has taken place suddenly from accident, apoplexy, or acute disease, the body has been observed to retain its heat for a long period.

Can the warmth of the human body be retained in its normal state for any length of time after death? We might suppose, *à priori*, that this question should be at once answered in the negative; but there are numerous authentic observations which show that heat may be sometimes long retained by the dead body, both on the surface as well as in the cavities; and it has been noticed, in certain fatal diseases, that the temperature has actually risen in the body after death. This exceptional retention of heat has given rise to the erroneous suspicion that the person was still living. Doubts were entertained for several days respecting the death of the well-known Professor Dieffenbach, of Berlin. The unusual retention of heat, and the delay of the putrefactive process, led to the supposition that he was only in a state of apparent death.

It can scarcely be imagined that the production of heat should continue in a really dead body: and yet certain facts connected with the malignant cholera, yellow fever, and other diseases, appear to establish the possibility of this. In some cases of death from malignant cholera, when epidemic in this country, in 1832-3, the body, which had become moderately cold, was observed suddenly to resume its warmth, so that the temperature is stated to have risen some time after death as high as 87° , although circulation and respiration had entirely ceased. In another instance the temperature was observed to rise from 79° to 92° after death. This singular phenomenon, like numerous others connected with that disease, has received no adequate explanation. According to Valentin, the occurrence of post-mortem heat is common to all dead bodies, the difference being only in degree. It is said to be most rapidly developed after death from injuries to the nervous centres, especially the brain. In cerebro-spinal meningitis, the temperature has risen after death from 104° to 111° Fahrenheit, and in a fatal case of smallpox, attended with much delirium, Simon observed that the thermometer rose at death from 104° to 113° ("Lancet," 1870, vol. i. p. 21). This production of heat after the cessation of breathing must be taken as positive evidence of some latent vital power or chemical force still lingering about the circulating system; for in real death, the animal body, when it has once become cold, is no more capable of spontaneously generating heat within itself than any of the inert and lifeless solids by which it is surrounded.

In a case of death from Asiatic cholera, Mr. Rumsey observed that half an hour after the complete cessation of respiration and circulation, the muscles of the arm underwent spontaneously various motions of contraction and relaxation, continuing for upwards of an hour, and that although previously cold, they then became evidently warmer. The restoration of warmth after the body has become cold in such cases, can only be explained by supposing that there still remains about it some lingering trace of vital action; although this may not be indicated by the presence of the ordinary signs of active life. The facts connected with the production of heat in the dead body have not received much attention from physiologists.

Dr. John Davy met with some very high temperatures in the *dead* body. In a case of rheumatism, after the viscera had been exposed for nearly ten minutes, the mercury of a thermometer, placed under the left ventricle, rose to 113° , and when in contact with the lobulus Spigelii of the liver, to 112° . In a second subject, examined *six hours* after death, the thermometer under the left ventricle indicated a temperature of 108° , and when in contact with the lobulus Spigelii, 107° . In these cases, the patients were ill but a short time, and died suddenly; and the temperature of the apartment in which the observations were made was 86° . This increase of temperature after death has been referred to putrefaction; but Dr. Dowler has shown that it takes place soon after death, and before rigidity sets in. Some of the cases reported by Dr. Wilks and myself also show that it may take place independently of putrefaction. ("Guy's Hosp. Rep." Oct. 1863, cases 4, 26, 30, p. 184.) Dr. Dowler has called this condition *post-mortem calorificity*; he has noticed it as a common occurrence, in a warm climate, in the bodies of persons who have died from yellow fever. The heat of the body, according to him, continues to increase for several hours after death. The alleged effect of loss of blood in accelerating the cooling of the human body when death has occurred suddenly from hemorrhage, has no foundation in fact. The only physical difference which it would be likely to create would be by simply reducing the amount of fluids in the body to undergo the cooling process. In a well-marked case, the loss of four pounds made no appreciable difference in the rate of cooling.

3. *Cadaveric rigidity. Rigor mortis.*—In from five to six hours after death, and generally while the body is in the act of cooling, the muscles of the limbs are observed to become hard and contracted in the attitude in which the body is placed; the joints are stiff, and the trunk is firm and unyielding. This peculiar condition of the muscles is known under the name of cadaveric rigidity. The first effect of death from any cause is in most cases a general relaxation of the whole of the muscular system. The lower jaw drops, the eyelids lose their tension, the limbs are soft and flabby, and the joints are quite flexible. The muscular tissue may be considered as passing through three stages in a dead body. 1. It is, at first, flaccid, but contractile, although it may be remarked that muscles contracted by living force in the act of dying, do not necessarily become relaxed in death; 2. It becomes rigid and incapable of contraction; and 3. It is once more relaxed, and does not regain its power and contractility. The body now undergoes those chemical changes which are indicative of putrefaction. The first of these stages defines the duration of muscular irritability; the second, that of cadaveric rigidity; and the third, that of the commencement of putrefaction.

The *time* at which rigidity occurs after death, as well as its duration, is affected by various circumstances. It generally commences within *five* or *six* hours, and lasts from sixteen to twenty-four hours. Experiment shows that the *seat* of this phenomenon is in the muscular system, for the rigidity disappears immediately on the removal or division of the muscles. According to the experiments of Béclard and others, the rigid condition of the muscles is wholly independent of the integrity of the

nervous system: for a division of the nerves leading to the particular muscles, or even the entire removal of the brain, has not been found to prevent it, or to retard its occurrence. It has also been observed that when death has taken place from paralysis, hemiplegia, or apoplexy, the rigidity has been as strongly manifested by the muscles of the paralytic or hemiplegic, as by those on the healthy side, provided they are well nourished and retain some irritability. The muscles of shattered limbs, in death from comminuted fractures, do not take on this condition. It is probable that the rigidity is due to a vital action in the muscular fibre; and possibly, as John Hunter imagined, it may be the last effect of the vital force on the muscular system. According to Kussmaul, the living metamorphosis of the muscle has ceased; the muscle becoming rigid is a dying—the perfectly rigid is a dead muscle. Rigidity is in general observed to take place simultaneously with the coagulation of the blood throughout the body. Some have considered it to depend upon this; but not to mention that the alleged cause appears to be wholly inadequate to the effect produced, the rigidity sometimes occurs while the body is warm and the blood fluid, therefore this cannot be the true explanation: moreover, it closely resembles the rigidity of syncope and asphyxia, which can have no reference to the coagulation of the blood.

Cæteris paribus, rigidity is always more strongly manifested, and continues for a longer period, in those bodies in which the muscular system is healthy and fully developed. It has been observed that the time at which it appears after death in muscular subjects is longer than in other cases.

In a case of death from hemorrhage, in which four pounds of blood were suddenly lost from the axillary artery, it was observed that eight hours after death the arms and legs were pliant; and it was not until twelve hours after death, when the body was becoming cold, that rigidity manifested itself. Death from hemorrhage, therefore, does not accelerate this condition; it seems to have no more influence upon the period of its occurrence than it has upon the cooling of the body. So with regard to irritant poisoning in an acute form; no difference was observed in reference to the rate of cooling or the commencement of rigidity in a well-marked case of death from arsenic, in eleven hours. In a case of suffocation by charcoal vapor, Nysten observed that rigidity did not make its appearance until *sixteen* hours after death, and it is stated to have lasted for the long period of *seven* days. In other instances of suffocation, this protraction of cadaveric rigidity has not been noticed.

In these cases, the slow access of this depends less on the mode of death than on the irritability of the muscles at the time of death. This is always great when the nutrition of the muscles is perfect, a condition which exists in cases of violent death, as from decapitation, sudden hemorrhage, or some form of asphyxia. Dr. Symonds has seen a body in a state of rigidity eight days after death by hanging. Nysten found that there was muscular irritability in the body of a decapitated man twenty-six hours after the head had been severed from the body; and Brown-Séquard states as the general result of his experience, that in the bodies of healthy persons decapitated or asphyxiated, cadaveric rigidity did not appear sooner than ten or twelve hours after death, and that it lasts more

than a week, even when the weather was warm. He found in the muscles of the limbs of two decapitated men some degree of irritability, thirteen and fourteen hours after death.

According to Nysten, cadaveric rigidity first appears in the muscles of the trunk and neck; it then takes place in the muscles of the upper extremities, and lastly, in those of the lower. In regard to its disappearance, the muscles of the lower extremities will often be found rigid while those of the trunk and upper extremities are in a state of relaxation. In the particular limbs, it commonly proceeds from above downwards, and it generally passes off in the same order. It always sets in, increases, and decreases imperceptibly and gradually, in which respect it differs strikingly from the rigidity of muscles as a result of disease.

It will now be necessary to consider whether a *living* body ever assumes a condition analogous to that of cadaveric rigidity. Tetanus, apoplexy, catalepsy, hysteria, syncope, and asphyxia have been stated to present symptoms which might lead to doubt respecting the reality of death from this sign. There are, however, these striking differences: in rigidity from any of these diseases, the warmth of the body is commonly in great part preserved, if not on the surface, in the rectum and flexure of the joints; the rigidity of disease takes place simultaneously with the apparent suspension of life from the attack; and lastly, the whole of the body becomes equally rigid at the same moment, owing to the existence of a universal muscular spasm.

The observations of M. Brown-Séquard have furnished an explanation of many of the difficulties connected with the occurrence and disappearance of cadaveric rigidity. ("On the Relations between Muscular Irritability, Cadaveric Rigidity, and Putrefaction." "Proc. R. S.," May, 1861, p. 204.) This physiologist agrees with Nysten and others that the greater the degree of muscular irritability at the time of death, the later cadaveric rigidity sets in, and the longer it lasts; and the later also putrefaction appears, and the more slowly it progresses. Müller and Gierichs had already shown that rigidity does not occur until the muscles have lost their irritability, or their power of contracting on the application of ordinary stimuli; that in frogs, in which, as in other reptiles, muscular irritability is very persistent, rigidity is often not established until three or four days after death; that in birds, on the other hand, in which muscular irritability remains but a short time after death, rigidity ensues quickly. Further, all circumstances which cause a speedy exhaustion of muscular irritability during life, induce an early occurrence of cadaveric rigidity, while those conditions by which the appearance of irritability is delayed, retard its access. ("Baly and Kirke's Physiology," 1848, p. 9.) M. Brown-Séquard observed, as a result of his experiments on animals, that when the temperature of the muscles was diminished before death, their irritability lasted long after death; cadaveric rigidity set in late, and lasted long; and putrefaction appeared late, and proceeded slowly. Whatever exhausts muscular irritability, such as violent exercise and exertion, accelerates rigidity in the dead, and, in an equal degree, putrefaction; this applies to observations on man, as well as on animals. Rigidity takes place rapidly in the dead bodies of cattle that have been overdriven, or of animals that have been

lamed to death. The bodies of soldiers killed in the early part of a battle become rigid slowly, while the bodies of those who are killed at the close, after many hours of violent muscular exertion, become rigid almost immediately. This may explain the singular fact recorded by military men, that the dead bodies are sometimes found on the field of battle stiffened in the attitude of kneeling or sitting, with their weapons clutched firmly in their hands. There has been no relaxation in death, but the muscles appear to have at once passed from a living contraction into a rigid condition. This also throws light upon a fact to be presently noticed, that suicides are sometimes found with weapons grasped in their hands, and their bodies stiffened in the attitudes in which they have died. It may be inferred in these cases that from some cause operating during life, the muscular irritability was exhausted at the time of death. Hence the greatest differences are observed to exist in regard to the commencement of cadaveric rigidity and putrefaction, in consequence of the variable degree of muscular irritability at the time of death. Dr. Brinton, U. S., has recorded his experience in this curious subject during the American war. In many who had died instantaneously from brain and heart-wounds, the body was rigid throughout, and the position was that of the last moment of life. He has called this *instantaneous rigor*. After the battle of Antietam, in 1862, he counted within a small space forty dead bodies, mostly with chest wounds. There were some with their arms raised rigidly in the air, and others with their legs drawn up and fixed. In not a few the bodies were curved forward and fixed. These attitudes were not those of the relaxation of death, but were rather of a seemingly active character, and the muscles remaining rigid and inflexible as the result of spasmodic muscular action in the last moment of life. ("Amer. Jour. Med. Sci.," Jan. 1870, p. 87. Also "Lancet," 1870, 1, 276.) In reference to deaths from malignant cholera, Brown-Séquard observed that cadaveric rigidity appeared late and lasted long in those patients who died quickly, that is, before a prolonged alteration of nutrition, and that those muscles which had been attacked with violent and frequent cramps became rigid very soon after death, and remained so only for a short time. M. Ollivier found that the bodies of cholera patients were frequently rigid in from six to eight hours after death, while the muscles which were the seat of this rigidity were still warm, and on making an incision into them, the blood readily flowed out.

A similar error has arisen respecting the bodies of persons killed by lightning. John Hunter thought that cadaveric rigidity did not occur in his mode of violent death: but the late Sir B. Brodie found that the body of an animal killed by electricity became, as usual, rigid after death.

At a certain period after death, the heart is found rigid and firmly contracted. If examined at this time, it may appear to be in a state of spasm, and to have its walls thickened, while the cavity of the left ventricle may be described as being much smaller than in the normal state. Sir James Paget has pointed out that this natural condition of the heart after death has led to pathological mistakes, the walls being described as thickened, and the cavities diminished in size, and the heart being in a state of concentric hypertrophy from disease. On the other

hand, the perfect relaxation of the heart which follows at a later period after death, has been mistaken for, and described as a morbid flabbiness and flaccidity. Spasm and paralysis cannot be inferred to have existed when we discover these conditions of the heart in the recently dead body.

Under the action of poisons like strychnia, and those alkaloids which cause death by convulsions, the more violent and frequent the convulsions, the sooner cadaveric rigidity sets in.

4. *The Eyes*.—Shortly after death, the cornea becomes dull, its brightness and prominence disappear, the globe becomes collapsed, and, after a time, the surface of the membrane is wrinkled. Louis long since observed, that the eyes of the dead become flaccid and soft in a very few hours after dissolution, and that a film was formed over them; this condition he considered to be characteristic of death. It is necessary to observe, however, that while this appearance is not always met with in the dead body, it is sometimes found in the living. In those who have died from apoplexy, or from the inhalation of carbonic acid gas, the eyes have often preserved their brilliancy and prominence for a length of time. This has also been observed in those who have been poisoned by prussic acid, cyanide of potassium, or the essential oil of bitter almonds. Incipient putrefactive changes may, by forcing the blood towards the head, cause a prominence and brilliancy of these organs, in those bodies in which they were dull and collapsed soon after death. On the other hand, the film over the eye and the collapse of the globe have been observed in cases of malignant cholera several hours before death, and while the heart was still beating. (“Ann. d’Hygiène,” 1848, 1, 104.)

5. *The Skin*.—After dissolution, the skin is observed to become extremely pallid and waxy-looking, owing to the absence of all circulation. In some parts it becomes covered, as the body cools, by livid discolorations (cadaveric ecchymosis); this is especially the case in those instances where death has taken place by sudden violence. One of the most striking changes in the skin is its entire loss of elasticity. In the living body, if any part of the surface be compressed, the skin will readily return to its original form on removing the pressure. Thus, in a doubtful case, a flatness of those parts which have been allowed to lie upon an even surface may be regarded as a sign of real death, provided the other concomitant changes are observed.

6. *Coagulation of the blood* has been enumerated among the signs of death.

The blood coagulates in most cases after death, but at a variable time after the cessation of the heart’s action. When blood is removed from the living body, coagulation commences in from five to ten minutes. In the dead body, it probably does not commence until it begins to cool. Hence the fact of coagulation does not prove that the person is living. Dr. Wilks has observed that when a body is examined eight or ten hours after death, it is not unusual to find the blood which may have flowed from it as a liquid, forming a firm clot on the table; and that which is effused into the chest during the examination often forms after some time a very firm coagulum. (“Guy’s Hospital Reports,” Oct. 1863, p. 183.) It has been stated that the blood of persons killed by lightning does not coagulate, but this statement is erroneous. Certain diseases appear to

influence the coagulation of blood. Mr. Savory has observed that coagulation has been partial or imperfect in cases of death from delirium tremens; and it is well known that in rapid death from certain vegetable poisons the blood is found fluid and of a darker color than natural, even when the examination is made soon after death.

If we allow a proper interval to elapse after the supposed death of a person, there can be no difficulty in solving the question, whether the body is really dead, even before any of those changes which arise from putrefaction have manifested themselves. The circumstances on which we may rely as furnishing conclusive evidence of death, are the following: 1. The absence of circulation and respiration for at least *an hour*, the stethoscope being employed if necessary; 2. The gradual cooling of the body to the temperature of the air, the trunk remaining warm while the members are cold; and 3. As the body cools, a gradual supervention of a rigid state of the muscles, successively attacking the limbs and trunk, and ultimately spreading through the whole muscular system. When these conditions are observed, the proofs of death are conclusive; it is unnecessary to wait for any sign of putrefaction. These changes are as certainly the forerunners of putrefaction as the process of putrefaction is itself the forerunner of the entire destruction of the body. I believe it may be safely said that there has not been a single instance of resuscitation after rigidity had once commenced in a body. During the raging of epidemics, if additional evidence be required for early burial, it might be obtained a few hours after the supposed death, by exposing a superficial muscle to the galvanic stimulus. If the fibres do not contract, death is certain. If they do, this is no proof that the person can be restored to active life; but further time may be allowed before the body is committed to the grave.

Putrefaction.—By putrefaction we are to understand those chemical changes which spontaneously take place in dead animal matter, during which offensive gases are evolved. The ultimate effect of these changes is, after a longer or shorter period, to reduce the organic to the condition of inorganic compounds, consisting chiefly of water, ammonia, and carbonic acid. It is in the stage of transition that noxious effluvia are evolved from which the process derives its name. These consist of compounds of nitrogen, sulphur, phosphorus, and carbon with hydrogen.

This process does not begin to manifest itself in the dead body until after the cessation of cadaveric rigidity, and generally about the third day. It is then observed, if the body has been exposed to the atmosphere in an apartment of mean temperature (60°), that the limbs and trunk become supple and pliant, and yield a faint odor. The skin covering the abdomen becomes of a pale greenish color, which gradually deepens. A similar discoloration slowly makes its appearance in the chest, between the ribs, in the face, the neck, the legs, and lastly, in the arms. The color appears to depend on the decomposition and infiltration of the animal fluids, especially the blood, into the skin. In the neck and limbs it is observed to be more marked in the situation of the large venous trunks; and sometimes, indeed, the course of the superficial veins is accurately traced out by greenish-blue or dark lines, which have been mistaken for marks of violence. Gaseous products are formed, not

only in the hollow organs of the abdomen, but beneath the skin generally, so that on making an incision, the edges of the skin are rapidly forced apart or everted. The reaction of this confined gas accounts for the occasional escape of alimentary and fecal matters from the outlets; as also for the escape of blood some days after death from wounds involving any of the large veins.

The gases generated in the cavities of the head and face by putrefaction, appear to meet with the greatest resistance to their escape. The features become generally swollen or bloated, one or both eyes may be protruded, the eyelids swollen and dark colored, the lips swollen and the tongue protruded between them, gaseous matter with fluid escaping in bubbles from the mouth and nostrils. As the skin of the face is generally livid or even black, it is impossible, under these circumstances, to recognize a person. In death from drowning, when the body is afterwards exposed to a warm atmosphere, the gases of putrefaction are so copiously produced that the head appears much larger than natural, and the skin of the trunk and limbs is distended with gas, giving to the whole of the discolored body a bloated appearance. It is the accumulation of these gases in the chest and abdomen of a drowned body, which gives to it buoyancy and causes it to float.

Changes in the Viscera.—During putrefaction, various discolorations take place on the mucous surface of the stomach and bowels, which often closely simulate the effects of disease or poison. The mucous membrane of the stomach may be found of various tints—from a red-brown, becoming of a brighter red by exposure to the air, to a deep livid purple or slate color, and sometimes black from a decomposition of the blood. At the greater end, where the stomach is in contact with the spleen or liver, the lividity is often well marked and clearly defined through all the coats. The peritoneal or outer coat is of a greenish hue, and the course of the superficial vessels is marked by greenish-brown or black lines. These spontaneous changes, which are the result of putrefaction, may be easily mistaken for the effects of irritant poisoning. There are no rules that I am aware of which will always enable a medical jurist to distinguish such cases. Much must depend on the progress of putrefaction, and the period after death at which the body is examined; hence, each case must be judged by the circumstances which attend it. We may presume that the redness has taken place during life, and is not a result of *post-mortem* changes: 1. When it is seen soon after death. 2. When it is met with in parts not dependent, nor in contact with other organs gorged with blood. 3. When it is accompanied by a considerable effusion of coagulated blood, mucus, or flakes of membrane, the result of ulceration, corrosion, or destruction of the coats of the viscera. When the body is not inspected until a long period after death, it is difficult to distinguish these pseudo-morbid appearances from those depending on the action of irritant poison. In a really doubtful case, it is therefore better to withhold an opinion, than to express one which must be purely conjectural.

Putrefaction takes place with variable rapidity. It commonly shows itself about the second or third day in warm weather, and about the fifth or sixth day in cold weather. In some instances, however, the

body has been found in an advanced state of putrefaction in the short period of *sixteen hours* after death, and in others the process has been greatly protracted. The time of its appearance is dependent on the duration of cadaveric rigidity, and the condition of the body at the time of death.

It never begins until cadaveric rigidity has ceased, and therefore not until the muscles of the body have entirely lost their irritability. Whatever conditions of the body during life after death may operate to cause the disappearance of muscular rigidity, will *pari passu* accelerate rigidity and putrefaction, and *vice versa*.

There are three primary conditions which are indispensable to the establishment of this process in a dead body. These are: 1st, a certain temperature; 2d, the presence of moisture; and 3d, the free access of air.

Temperature.—The process is found to go on most favorably in a temperature varying from 70° to 100° . It will commence, other circumstances concurring, at any temperature above 50° ; but at 32° it appears to be wholly arrested. The dead body may thus be preserved a considerable time in snow, ice, or in a frozen soil; but if, after removal, it is exposed to a temperature between 70° and 100° , the ordinary putrefactive changes are stated to take place with more than their usual rapidity. At a high temperature, again, *i. e.*, about 212° , putrefaction is arrested. The soft animal solids lose their water, become hard and brittle masses, and may now be exposed to the atmosphere without undergoing any further change. A heat between 100° and 212° may also speedily put a stop to the process, by causing a rapid evaporation of the water contained within the solids. They become thereby dried and coagulated. Thus it is that bodies buried in the hot and arid sands of Egypt are dug up, many years after interment, in a state of desiccated mummies, putrefactive decomposition having been long since arrested. The effect of temperature on this process is strikingly seen in the influence of season. A dead body exposed to air during summer, when the thermometer is above 60° or 70° , may undergo more marked putrefactive changes in twenty-four hours, than a similar body exposed for a week or ten days in winter. This is a fact which demands consideration, when an opinion is required to be formed respecting the date of death of a body concerning which nothing is known.

The presence of moisture.—Unless the animal substance is impregnated with water or moisture, it is impossible that putrefaction can take place. The animal solids commonly contain sufficient water for the spontaneous establishment of the process. In a human body weighing 150 lbs., there are about 100 lbs. of water ("Brande and Taylor's Chemistry," p. 831). The soft organs differ much from each other in respect to the quantity of liquid contained in them, and therefore in the degree in which they are prone to putrefaction. Thus, the brain and the eye are in this respect contrasted with the teeth, bones, hair, and nails. The fluids of the eye are rapidly decomposed, while the teeth and hair may remain for centuries unchanged.

Influence of air.—Putrefaction may take place to a slight extent independently of air, but the process is soon arrested; and hence bodies

sealed permanently in leaden coffins are found perfect and may be identified after very long periods of time. The products in all cases in which the air is excluded, are chiefly of an ammoniacal nature. Air operates by its free oxygen combining with the animal elements, and forming gaseous and liquid products.

[Besides these external causes, there are others, subjective or inherent in the body, such as age, sex, state of the body, manner of death, influence of disease, etc. Aged bodies decompose slowly, probably on account of their comparative want of moisture; whilst the bodies of newborn children rapidly putrefy, for the opposite reason. Fat and flabby bodies undergo decomposition more rapidly than lean ones, because they contain more fluids; the same is said to be true of the bodies of women dying in childbed. In cases of very sudden death in persons of previously sound health, putrefaction is more rapid than when it has resulted from an exhausting disease. When the blood has been impoverished, as in typhus, and when the body has previously been much contused (provided it has not been protected from the influence of the air, as when buried under rubbish), the process of decomposition is accelerated. It is also rapid after death from suffocation by smoke, coal-gas, or sulphuretted hydrogen; also by strangulation, drowning, and asphyxia generally; also after narcotic poisoning; but it is slower after death from phosphorus, alcohol, sulphuric acid, and arsenic.

The order of decomposition of the internal organs, according to Prof. Casper, is as follows: Trachea and larynx, brain of young infants, stomach and intestines, spleen, omentum and mesentery, liver, brain of adults, heart and lungs, kidney, bladder and œsophagus, pancreas, diaphragm, large vessels (especially the arteries), and last of all, the uterus. R.]

Cadaveric lividity and ecchymosis.—There are certain external changes which take place in a dead body before the access of, or during putrefaction, to which it is necessary that a medical jurist should attend. There is what is called *cadaveric lividity*, which comes on during the act of cooling. At a still more advanced period, dark livid spots or patches are met with in the skin, to which the name of *suggillation* or post-mortem ecchymosis has been given (see "Henke Zeitschrift der S. A.," vol. i. p. 199). These appearances have often been mistaken for the effects of violence applied during life, and serious mistakes have thence arisen. Innocent persons have been accused of murder or manslaughter, and have been tried on charges afterwards proved to be groundless. Sir R. Christison refers to two cases, in one of which two persons were convicted, and in the other, three narrowly escaped conviction, upon a mistake of this kind.

These spontaneous changes in the dead body must, therefore, be attended to by the surgeon. They may be considered by dividing them into those which take place *before putrefaction*, and those which take place *afterwards*.

The first form (before putrefaction) is dependent on a stagnation of blood in the capillary vessels. So long as there is life, the capillary circulation continues. This may be ascertained by puncturing the skin or lip with a fine needle; if the capillary circulation is going on, a drop of blood will escape, otherwise not. When after death the capillaries

have lost their contractility, the blood appears to stagnate in them in an irregular manner, producing *lividity*. The skin of the body, although pale at the time of death, becomes covered during the act of cooling by extensive patches of a bluish or slate color, diffusing themselves over the greater part of the trunk and limbs. The color is sometimes of a deep purple, often mottled, but generally abruptly terminating in the white skin. This kind of ecchymosis is chiefly seen on the bodies of those who have died suddenly in full health, or by a violent death, as in apoplexy, hanging, drowning, suffocation from charcoal vapor, and other causes. In the latter case, it has been found in some instances to be especially developed. It is rarely seen in the bodies of those who have died from the loss of blood; the skin is in these cases commonly pallid. When the skin in which the lividity is seated is divided, it is seen that the color is confined to the upper layer of the true skin (*cutis*) or to the space between the cuticle and cutis, and never to extend through the latter. There is no sanguineous effusion, but apparently simple congestion in the minute capillary vessels.

Sometimes this lividity is disposed in a peculiar form over the body. If a stout and muscular person has died suddenly, and the body, wrapped closely in a sheet, is allowed to cool, the lividity may be sometimes disposed in the form of a number of stripes or bands over the whole surface—the congestion of the vessels taking place in the interstices of the folds, while the parts actually compressed remain white. The appearance of the body is such that we can hardly divest our minds of the idea that the person must have been flogged. The unbroken state of the cuticle, with the other characters just now mentioned, are, however, sufficient to distinguish this appearance from the effects of violence. This kind of lividity is known under the name of *vibices*. It is often seen on the backs of subjects that have been allowed to cool either in their clothes or on any rough and uneven surfaces. A few years since I saw a well-marked case of *vibices*, in which the suspicion was so strong that violence had been used to the deceased, that a coroner's inquest took place. The forepart of the body was covered with stripes, which were of a red and livid color: they appeared to correspond exactly to the folds of a sheet drawn tightly across the chest; and it was subsequently ascertained that the body of the deceased had been treated in this manner after death. The blood was superficially diffused, and the cuticle uninjured. The circumstance above mentioned at once satisfactorily explained the cause of the appearance. These *vibices* or weals, like the cadaveric lividity already described, are commonly seen in plethoric persons; they indicate great vigor of circulation at the moment of death. But lividity in the dead body occasionally presents itself under a more deceptive form than in either of the instances just mentioned. This is well shown in the case of a man who died November, 1837, on board of the Dreadnought hospital ship. The subject of this case, æt. 33, died suddenly from disease of the heart. Just before death the deceased had been auscultated, and no marks then existed on the skin. The body, after about eighteen hours, was examined, and then it was found to present in detached places, patches of discoloration or ecchymosis, varying in size from small spots to several inches in diameter. Although closely

simulating bruises or marks of violence during life, a slight examination showed that they were owing to simple lividity, because those parts of the back and limbs which were not compressed by the surface on which the body of the deceased was lying, were the only parts discolored. The calves of the legs, the loins, and the back, which bore the pressure were white. On cutting into these patches, the layers of the skin, as well as the tissues beneath, were throughout reddened by congested blood, and small rounded semi coagulated masses oozed out from the cellular membrane on slight pressure.

These characters somewhat resembled those produced by violence on the living body; but there was another, and, I believe, an unexampled circumstance, in which the resemblance to *vital* ecchymosis existed. Around many of the patches there was a wide border, or zone of a pale straw color, with various shades of green and blue, precisely similar to those which are seen in the gradual disappearance of an ecchymosis from the living body. By most medical jurists it has been hitherto considered that the zones of color are peculiar to *vital* ecchymosis, and are never seen in the ecchymosis produced after death. The occurrence of this case shows with what caution general rules should be framed for medico-legal practice. Had the body of this person been found lying dead and exposed on a high road, and had it been proved that another man had been seen quarrelling with him, what might have been the opinion expressed? We can scarcely hesitate to say, unfavorable to the accused person. This kind of ecchymosis could have been distinguished from that kind of violence during life only by the unruffled state of the skin, and the slight effusion of blood, compared with the extent of discolored surface. It is worthy of note, also, that the chief seat of ecchymosis was in those parts which were recumbent or depending. The formation of the colored zones around some of the patches of lividity was fully explained by the fact of the man having labored under general dropsy. The serum effused in the cells here acted upon and diluted the liquid blood, as it exuded from the vessels, and diffused it around, much in the same manner as the serous exhalation of the cellular membrane acts on the blood effused in the living body.

In reference to putrefaction of bodies buried in the earth, this depends greatly on the permeability of the soil to air. M. Hoffmann, of Vienna, gives the following table of the relative permeability of soils, from the researches of Fleck. Assuming that dry gravel exempt from clay, has its permeability by air represented by 100, then dry gravel with clay would be 34.50; sand dried in air 27.47; and argillaceous gravel saturated with moisture would be 18.13.

The changes caused by putrefaction in the dead body have in some cases been mistaken for those of *gangrene* in the living, and a person has in consequence been wrongly charged with manslaughter. Parts which are the seat of severe injury at the time of death, undergo putrefaction more rapidly than those which have not been affected by the accident. When a body has undergone putrefaction generally, the effects of *gangrene* in a wound may be merged in the changes caused by this process, and great care should be taken in assigning these changes to one or the other condition. *Gangrene* implies the death of a part in the living

body, and putrefactive changes take place in the dead part, as in the entire dead body. If changes resembling those of gangrene are found in a wounded limb, while the rest of the body is not in a putrescent state, there may be some reason for the opinion that there was gangrene during life. In this case, however, due allowance should be made for the more rapid decomposition of wounded parts. The best evidence will be that which shows the actual condition of the injured part in the living body. If putrefaction is advanced, the opinion of a person who has not seen the deceased while living, can be little more than a conjecture.

Adipocere.—The substance called *adipocere* was first observed and described by Fourcroy during the removal of vast numbers of bodies from the Cimetière des Innocens in Paris. He gave to it this name, owing to its properties being intermediate between those of wax and fat. He considered it to be constituted of fatty matter and ammonia. From an analysis by Chevreul, the substance described by Fourcroy was proved to be a real ammoniacal soap with some extraneous coloring matter, which gave it a yellowish or brown color. It contained, besides, a bitter substance not defined, and an odoriferous principle, to which it owed its smell. Chevreul also detected in some specimens, lime, potash, and salts. The composition of *adipocere* does not appear to be uniform: it is liable to vary according to the nature of the medium to which the body has been exposed. Thus, in hard or river water, the white substance so-called, discovered in the dead body, is formed of a base of lime; so, in bodies laid in graves or vaults which are traversed by springs of water containing sulphate or carbonate of lime, an *adipocere* of stearate and oleate of lime is found as a hard white solid. It is not improbable, as Orfila has suggested, that in the first instance an ammoniacal soap is produced, and that this is subsequently converted into a calcareous soap by contact with calcareous water.

Any part of the human body may undergo this change, but all parts are not equally susceptible of it. In order that the *adipocere* described by Fourcroy should be found, it is indispensable that the animal fat should be in contact with substances containing nitrogen. Experiment has clearly established that neither pure fat, nor pure fibrin, when kept apart, will become saponified. Orfila found by comparative experiments, that the skin deprived of all fat did not undergo this change; but when the fat was allowed to adhere to it, it became saponified. Upon the knowledge of these facts, the following theory of the production of *adipocere* was founded. The fat, containing no nitrogen, could not furnish ammonia; consequently it could not spontaneously change into this substance. The fibrin of the muscular system was therefore supposed to produce ammonia by giving off hydrogen and nitrogen; and this alkali combined with the fatty acids of the body to form a soap (see "Ure's Dictionary," art. *Adipocere*). As the fat of the body is contained in a cellular membrane (a nitrogenous compound), and is traversed by the blood and other nitrogenous fluids, the nitrogen is as readily furnished by these as by the fibrin of the muscles. So again, the skin and fat, separated from the muscles, will become converted into *adipocere*. The fibrin of muscles, therefore, although unquestionably it may be one source of the ammonia, is not the sole source. Oil or fat exists through-

out the soft organs and tissues of the whole body; hence every part may undergo this transformation. When the change is complete, the body maintains its condition for many years. Thus, in one instance, after seventeen years' burial in a grave, an exhumed body was found to be converted into this substance, and many of the organs could still be identified ("Phil. Med. Exam.," April, 1847, p. 247).

The period required for saponification to take place varies according to circumstances. Devergie states that the body of a newly-born child in the soil of water-closets may become entirely saponified in from six weeks to two months; while in a drowned subject in water, saponification may be partially met with in three or four months; and in one buried in a damp grave, from two to three years may sometimes elapse before saponification is complete. There is no doubt, however, that the process may take place partially in the dead body within much shorter periods than these. A body floating in water has been found converted into this adipocereous state in a little more than five weeks; and with regard to the period in an ordinary grave, I may refer to the case of a female, exhumed at Bristol, in 1835, after fourteen months' interment. The lower part of the body was here found adipocereous. It appears that the grave was very damp, and the line of adipocereous transformation in the deceased was bounded by the level to which the water had reached. These facts are of more importance than may at first sight appear, since a legal question of survivorship, in at least two cases, has turned upon the shortest period required for the production of true adipocere in the dead body.

Properties of adipocere.—Fourcroy and other French chemists described adipocere as an unctuous, soapy substance, varying in color from a pale white to various shades of yellow or brown. In the first instance it is soft, but becomes harder and lighter in color when dried. It melts at 200° , and when strongly heated in air gives off an ammoniacal odor, inflames, and burns. It is easily suspended in cold water, and forms an opaque mixture on boiling. Acids decompose the solution by combining with the bases, forming salts. When heated with lime, ammonia is evolved. It is only partly dissolved by boiling alcohol. Adipocere with a calcareous base is harder and whiter than that which contains ammonia. There is no trace of organic structure in either.

Inspections.—The necessity for appointing a skilled independent inspector of bodies in all suspected cases demanding inquiry, will be apparent from other considerations. Under the present system, a person who has destroyed the life of another by poison may be present at the post-mortem inspection of the body of his victim, and may use his efforts to defeat the objects of the inquiry. William Palmer, a medical man, was thus allowed to be present at the inspection of the body of Cook. He nominated the persons, one of them an inexperienced young man who had never before inspected a body in a case of death from poison, and he stood over them while they were engaged in the office. The stomach of the deceased when received for analysis was cut open throughout its length. The injury to this organ, by which at least a portion of the contents was lost, occurred during the inspection, and is said to have arisen from Palmer having accidentally (as it was alleged) pushed against

the youth who was making the inspection. After the viscera had been placed in a jar and secured with a bladder, Palmer found an opportunity of cutting the bladder with a knife and inverting the jar, and this probably led to a further loss of the contents. In a case of exhumation in which I was consulted, the viscera had been carefully removed and placed (as it was supposed) in separate jars, which were properly secured and labelled. When the jar labelled "Stomach and Contents" was opened by the analyst to whom it had been sent, it was found empty. From inquiries subsequently made, there was but little doubt that a person who was interested in preventing an analysis was permitted to be present at the inspection, that he had taken the opportunity, when the inspectors were otherwise occupied, of removing the stomach from the jar and again secretly returning it into the abdomen before the body was sewn up, or otherwise disposing of it. Acts of this kind should be impossible in the present day, and the best security against their occurrence would be the appointment of a skilled inspector in a district, to conduct all post-mortem examinations for coroner's inquests.

A charge of malapraxis is sometimes raised against a medical man, in consequence of the death of a patient. The examination of the body may, by order of a coroner, be unknowingly placed in the hands either of a professional rival, or of a friend of the person inculpated. This is not just, either to the practitioner or the public. There is nothing more easy, medically speaking, than to exaggerate appearances in a body, or to assign to the actions of medicines, or to the use of surgical instruments, post-mortem conditions to which an independent and experienced anatomical inspector would probably attach no importance. Supposing the question to be that a patient has died from an overdose of opium, said to have been found in the stomach—if the analysis has been intrusted by a coroner to any professional rival, or to an incompetent analyst selected by him, the injury done may be irreparable. These are not imaginary cases: they have occurred and must occur until special inspectors and analysts are appointed in place of men who are now taken by chance, by the fact of their living in the vicinity, or of their being called to see the person while dying.

[In cases involving the all-important issues of life and death, we cannot but regard it as a serious error to commit the responsible duty of the exhumation of a body, and its subsequent anatomical and chemical examination *exclusively* to the State's experts, where no opportunity is allowed to the experts for the defence to be present. To say the least, such a procedure has very much of an *ex parte* look, and must necessarily subject the persons thus professionally employed to a suspicion of prejudice. In the "Review" of the Wharton-Ketchum trial ("Amer. Journ. of Med. Sci.," April, 1872) we took occasion to condemn this practice as unfair both to the accused and to the cause of justice. In this case, the body of the deceased was thrice examined, and *exclusively* by the State's expert witnesses; and, on one of these occasions, secretly—without even the knowledge of the counsel for the defence!—R.]

POISONING.

CHAPTER IV.

DEFINITION OF THE TERM POISON.—DEADLY POISONS.—MECHANICAL IRRITANTS.—LAW IN RELATION TO THE ADMINISTERING OF POISONS.—INFLUENCE OF HABIT AND IDIOSYNCRASY.—CLASSIFICATION.—SPECIAL CHARACTERS OF IRRITANT, CORROSIVE AND NEUROTIC POISONS.

Definition.—A POISON is commonly defined to be a substance, which, when administered or taken *in small quantity*, is capable of acting deleteriously on the body; in popular language, this term is applied only to those substances which destroy life in small doses. This popular view of the nature of a poison is too restricted for the purposes of medical jurisprudence. It would obviously exclude numerous compounds, the poisonous properties of which cannot be disputed—as, for example, the salts of copper, tin, zinc, lead, and antimony; these, generally speaking, act as poisons only when administered in *large* doses. Some substances, such as nitre, have not been observed to have a noxious action except when taken in large quantity, while arsenic acts as a poison in a small dose; but in a medico-legal view, whether a man dies from the effects of an ounce of nitre, or two grains of arsenic, the responsibility of the person who criminally administers the substance, is the same. Each may be regarded as a poison, differing from the other only in its degree of activity, and in its mode of operation. The result is the same; death is caused by the substance taken, and the *quantity* required to destroy life, even if it could be always accurately determined, cannot enable us to distinguish a poisonous from a non-poisonous substance. If, then, a medical witness be asked “what is a poison?” he must beware of adopting this popular definition, or of confining the term poison to a substance which is capable of operating as such in a small dose taken at once.

In legal medicine, it is difficult to give such a definition of a poison as shall be entirely free from objection. Perhaps the most comprehensive which can be suggested is this: “A poison is a substance which, when absorbed into the blood, is capable of seriously affecting health, or of destroying life.” There are various channels by which poisons enter the blood; some are in the form of gases or vapors; these operate rapidly through the lungs; others are liquid or solid, and these may reach the blood either through the skin or through a wound; but more commonly through the lining membrane of the stomach or bowels, as when they are taken or administered in the ordinary manner. The latter chiefly give rise to medico-legal investigations. Some substances act as poisons

by any one of these channels; thus arsenic is a poison whether it enters the blood through the lungs, the skin, or the stomach and bowels; but such poisons as those of the viper, of rabies, and of glanders, appear to affect the body only through a wound in the skin. When introduced into the stomach, these animal poisons have been found to be inert. In adopting the above definition of a poison in a medical sense, it is proper to remark that there are some substances which are regarded as poisons, although absorption into the blood does not appear to be necessary to their action. The mineral acids and alkalies belong to this class of bodies. They are corrosive poisons; they operate injuriously by causing the destruction of living parts: and whether applied to the skin, the stomach or (in the form of vapor) to the air-cells of the lungs, they destroy life by the local changes to which they give rise, and the inflammation which is a consequence of their action.

It is not easy to define the boundary between a medicine and a poison. It is usually considered that a medicine in a large dose is a poison, and a poison in a small dose is a medicine; but a medicine such as tartarized antimony may be easily converted into a poison, by giving it in small doses at short intervals, either under states of the body not adapted to receive it, or in cases in which it exerts an injuriously depressing effect. Some deaths have been lately occasioned by this wilful misuse of antimony in doses which might be described as *medicinal*, although in the cases referred to, no other intention could have existed, in the secret administration of this substance, than that of destroying life. A person may die either from a large dose of a substance given at once, or from a number of small doses given at such intervals that the system cannot recover from the effects of one before another is administered. This remark applies to a great number of medicines which are not commonly included in a list of poisons.

In reference to the *medical* definition of a poison it is necessary to observe that the law does not regard the manner in which the substance administered acts. If it be capable of destroying life or of injuring health, it is of little importance, so far as the responsibility of a prisoner is concerned, whether its action on the body is of a mechanical or chemical nature, and whether it operates fatally by absorption into the blood or not. Thus a substance which simply acts mechanically on the stomach or bowels may, if wilfully administered with intent to injure, involve a person in a criminal charge, as much as if he had administered arsenic or any of the ordinary poisons. It is, then, necessary that we should consider what the law strictly means by the acts of poisoning. If the substance criminally administered destroys life, whatever may be its nature or mode of operation, the accused is tried on a charge of murder or manslaughter, and the duty of a medical witness consists in showing that the substance taken was the certain cause of death. If, however, death be not the consequence, then the accused may be tried for the attempt to murder by poison (24 and 25 Vict., c. 100, s. 11, Aug. 1861). The words of this statute are general, and embrace all kinds of substances whether they are popularly or professionally regarded as poisons or not. Thus it is laid down that—

“ Whosoever shall administer, or cause to be administered to or taken

by any person, any poison, or *other destructive thing*, with intent to commit murder, shall be guilty of felony."

Whether the administering be followed by any bodily injury or not, the act is still a felony, provided the *intent* has been to commit murder. The attempt to administer or the attempt to cause to be administered to, or to be taken by any person, any poison or *other destructive thing*, with the like intent, although no bodily injury be effected, is also a felony (s. 14). If any doubt formerly existed whether the *external* application of poisons, *e. g.*, by wounds or ulcerated surfaces, would be included in the words "administering or taking," they are now entirely removed by the Criminal Law Consolidation Act (Aug. 1861). The 22d section specially applies to such an offence, and the 15th section provides that "Whosoever shall, by any means other than those specified in any of the preceding sections of this act, attempt to commit murder, shall be guilty of felony." Mr. Greaves justly remarks, with regard to this important addition to the statute law, that "the malicious may now rest satisfied that every attempt to murder which their perverted ingenuity may devise, or their fiendish malignity suggest, will fall within some clause of this act, and may be visited with penal servitude for life." ("Notes on Crim. Law. Consolidation," p. 49.) Under section 22 of this statute, in reference to attempted poisoning, some offences are comprised, which formerly escaped punishment: "Whosoever shall unlawfully apply or administer to, or cause to be taken by, or attempt to apply or administer to, or attempt to cause to be administered to or taken by any person, any chloroform, laudanum, or other stupefying or overpowering drug, matter, or thing, with intent, in any of such cases, thereby to enable himself or any other person to commit, or with intent, etc., to assist any other person in committing any indictable offence, shall be guilty of felony."

[The Revised Criminal Code of Pennsylvania, passed March 31, 1860, contains various provisions upon the subject of the use of poisons, which are substantially the same as the provisions of the English statutes mentioned in the text. (See §§ 81-83.) Section 70 forbids the sale of morphia, strychnia, arsenic, prussic acid, or corrosive sublimate, except upon the prescription of a physician or on the personal application of some respectable inhabitant of full age. In all cases, the word "poison" to be legibly marked on the label of the vessel in which it is contained. A memorandum of all sales other than under prescription of a physician to be kept in a register, with name and residence of purchaser, quantity sold, and date. Penalty for breach, a fine not exceeding \$50.—P.]

Poison is not always administered with intent to murder. On many occasions it has been mixed with food, and thus administered with a view to injure or annoy a person. Cantharides have been thus frequently given, and in one instance (Nov. 1859) eight members of a family suffered from severe symptoms of poisoning by reason of the wanton administration of this drug. In April, 1860, several members of a family suffered from severe sickness, as a result of tobacco having been put into water contained in a tea-kettle; and tartar emetic has been in some cases dissolved in beer or other liquids as a mere frolic, without any proved or probable intention on the part of the offender to destroy life. The case

of *McMullen* (Liverpool Autumn Assizes, 1856) revealed an extensive system of poisoning in the northern counties, in which tartar emetic was the substance employed. This drug, mixed with cream of tartar, was openly sold by druggists under the name of "quietness powders," and the evidence established that women gave these powders to their husbands with a view to cure them of habits of drunkenness. Hitherto, when the intent of murder was not proved, the offender has escaped, although great bodily injury may have been done by his wanton or malicious act. Sections 23, 24, and 25 of Consolidation Act, c. 100, provide for this omission:—

"23. Whosoever shall unlawfully and maliciously administer to, or cause to be administered to or taken by any other person, any poison or *other destructive or noxious thing*, so as thereby to endanger the life of such a person, or so as thereby to inflict upon such person any grievous bodily harm, shall be guilty of felony."

"24. Whosoever shall unlawfully and maliciously administer to, or cause to be administered to or taken by any other person, any poison or other destructive or noxious thing, with intent to injure, aggrieve, or annoy such person, shall be guilty of a misdemeanor."

"25. If, upon the trial of any person charged with the felony above mentioned, the jury shall not be satisfied that such person is guilty thereof, but shall be satisfied that he is guilty of the misdemeanor above mentioned, then and in every other such case the jury may acquit the accused of such felony, and find him guilty of such misdemeanor."

It will be perceived that the words of the statute leave the question "What is a poison?" to depend upon the medical evidence adduced; and in order to include all substances of an injurious nature, although they may not be strictly speaking poisons, the words "*destructive or noxious thing*" are employed. Hence, on these occasions, a medical witness must be prepared to prove that the substance was either a poison or a destructive or noxious thing. In a trial which took place at the Essex Lent Assizes, 1850 (*Reg. v. Hayward*), a woman was charged with administering *white precipitate* to her husband with intent to kill. She was acquitted on the ground that there was no evidence to show that white precipitate was either a poison or a destructive thing. It is, however, placed beyond doubt that this substance is not only capable of producing all the effects of an irritant poison, but of destroying human life; hence, this acquittal was based on a pure mistake. *White hellebore*, *Lobelia inflata*, and *Oil of turpentine* have been erroneously pronounced not to be poisons under similar circumstances; in fact, when this question is raised, unless the medical evidence received by a court be very closely investigated, great mistakes may arise, owing, perhaps, to want of experience, or want of reflection on the part of those to whom the question is put. Learned judges have taken different views of the meaning of the word *noxious*, and it is well that a witness should be on his guard in dealing with this question, "What is a noxious substance?" From a case lately tried in Cornwall, before Cockburn, C. J., it would appear to depend, not on the well-known nature of the substance, but on the *quantity* of it attempted to be administered. In *Reg. v. Hennah* (Cornwall Lent Assizes, 1877), prisoner was charged with administering

to a young woman a poison called cantharides, with intent to injure, aggrieve and annoy—the real purpose being to excite erotic feelings. The poison was given in two figs, and a glistening appearance which they presented, owing to the shining particles of cantharides, prevented the girl from eating them. One fig was examined by a druggist, and he found it to contain from a grain to a grain and a half of cantharides in powder. This would be equivalent to from two to three grains in the two figs. The druggist, in giving evidence, said that this quantity of cantharides would be insufficient to produce any effect upon the human system, and further stated, by a misquotation of this work, that a fatal dose would amount to twenty-four grains. It was ingeniously contended in defence that if what was administered could produce no effect, it would not in law amount to administering a “noxious” thing as required by the statute. This view was accepted by the Lord Chief Justice, and he directed an acquittal. He ruled that, unless the thing is noxious in the *quantity* administered, it cannot be said that there has been a noxious thing administered. He said further, that there must be a distinction between a thing only noxious when given in excess, and a thing which is a recognized poison, and is known to be a thing noxious and pernicious in its effect. The fallacy of this reasoning will be apparent when it is stated that cantharides is a poison recognized by law as well as in medicine; that it finds a place in the schedule of the Act for regulating the sale of *poisons*, by the side of strychnia, prussic acid, and arsenic; and further, that these substances operate as poisons or are noxious only when given in excess, *i. e.*, beyond a medicinal dose!

The court was no doubt misled on this occasion by relying upon the opinion of a retail druggist. The quantity of cantharides attempted to be administered was quite sufficient to cause irritation of the bladder, strangury, and other unpleasant symptoms, and this would surely come under the head of annoyance or injury to health. Dr. Maclagan reports an instance in which one grain and a half of cantharides, in three pills, caused strangury, and the substance was necessarily withdrawn. (“Brit. Med. Journ.,” April, 1877, p. 466.) In future cases of a similar kind a medical witness must be prepared to give an opinion not merely that the substance was noxious or poisonous, but that the actual quantity administered or attempted to be administered was noxious and likely to injure health, or to aggrieve or annoy a person. (See CRIMINAL ABORTION.)

Mechanical Irritants.—The substance administered may not be a poison in the medical signification of the term, and it may not be popularly considered as such, yet, when taken, it may be noxious to health or destructive to life. We have examples of substances of this description in iron-filings, powdered glass, sponge, pins and needles, and such like bodies, which have been administered with the wilful design of injuring, and have on various occasions given rise to criminal charges. In cases of this kind, the legal guilt of a prisoner may often depend on the meaning assigned by a medical witness to the words *destructive thing*. Thus, to take an example, liquid mercury might be poured down the throat of an infant, with the deliberate intention to destroy it. A question of a purely medical nature will then arise whether mercury be a

“destructive thing” or not; and the conviction of a prisoner will probably depend on the answer. Should a difference of opinion exist, an occurrence by no means unusual in medical evidence, the prisoner will, according to the humane principle of our law, receive the benefit of the doubt. The injuries produced on cattle by mechanical irritants have occasionally given rise to civil actions for damages. In *Newton v. Woodhursts* (Nottingham Autumn Assizes, 1871), the plaintiff claimed damages for the loss of three horses by reason of their having been killed by rice-meal supplied by the defendants. The horses were fed on the meal; they were taken sick and died. In the stomachs of each a large quantity of stuff was found containing five per cent. of sand. This had acted as a mechanical irritant, and caused death. From the evidence it appeared that the so-called meal consisted of the dust and refuse from the sweepings of the floors. The jury was discharged without a verdict.

Influence of Habit on Poisons.—Habit, it is well known, diminishes the effects of certain poisons; thus it is that opium, when frequently taken by a person, loses its effects for a time, and requires to be administered in a much larger dose. Indeed, confirmed opium-eaters have been enabled to take at once a quantity of the drug which would have infallibly killed them, had they commenced with it in the first instance. Even infants and children, who are well known to be especially susceptible of the effects of opium, and are liable to be poisoned by small doses, may, by the influence of habit, be brought to take the drug in very large quantities. This is well illustrated by a statement made by Mr. Grainger, in the “Report of the Children’s Employment Commission.” It appears that the system of drugging children with opium in the factory districts, commences as soon after birth as possible; and the dose is gradually increased until the child takes from fifteen to twenty drops of laudanum at once! This has the effect of throwing it into a lethargic stupor. Healthy children of the same age would be killed by a dose of five drops. The same influence of habit is manifested more or less in the use of tobacco, alcohol, ether, chloroform, morphia, strychnia, and other alkaloids. Sir R. Christison has remarked that this influence is chiefly confined to poisons derived from the organic kingdom; it is so limited with regard to mineral substances that it can scarcely be said to exist. It is stated on respectable authority that certain peasants in Styria are addicted to the practice of arsenic-eating, and that they carry it on for many years without suffering from the usual effects of this poison. Dr. Roscoe has published a case in which, according to information supplied to him, a Styrian peasant took in one day four grains and a half, and on the day following five grains and a half of arsenic, crushing the mineral between his teeth and swallowing it. The day after he had swallowed the second dose, the man left the place in his usual health, and there is no further record of him. Dr. C. Maclagan states that he saw a Styrian peasant, æt. 26, swallow between four and five grains of white arsenic in powder. In two hours, some urine which he passed contained arsenic. This man suffered no ill-effects; he stated that he had taken arsenic for a year and a half without any injury to his health. He took at first rather less than a grain every fortnight. In another case, a man, æt. 46, swallowed six grains. In three-quarters of an hour,

it was found that arsenic was eliminated with the urine. ("Ed. Med. Journ.," Sept. 1864, p. 200.) Dr. Knapp informed Dr. MacLagan, that a man once took in his presence seven and a half grains of arsenic, and no injurious effects were produced. ("Ed. Med. Journ.," Jan. 1865, p. 669.) Such cases as these admit of no explanation on English experience. Habit appears to have so little influence on arsenic, under the most careful medicinal use of it in this country, that I believe no medical practitioner has ever succeeded in causing a patient to take *two grains* at a dose, the smallest quantity yet known to have destroyed life. Mr. Hunt, who has had a large experience in the use of this mineral, fixes the maximum dose to be given with safety, at one grain.

The following case, reported in the same journal (August, 1864, p. 116), by Dr. Parkes, of Halifax, shows the danger incurred by this practice. A man who had taken arsenic for a period of three or four years died under the usual symptoms of chronic poisoning. As far as it could be ascertained, the daily dose taken by deceased for the last five months of his life, was from two to three grains. From the beginning of the practice he had suffered from symptoms of poisoning with arsenic, which gradually assumed the form of arsenical cachexia; but he referred the symptoms to other causes, and concealed the practice from his friends. His system never became habituated to the poison. This is the result which may generally be expected. If the exceptional cases observed in Styria are supposed to prove that arsenic may be taken in large doses with impunity they would lead to error. Such cases have no practical bearing in legal medicine. If the practice of arsenic-eating produces no symptoms, then no question of poisoning can arise. If, as in the above case, it does produce symptoms, then it falls within the range of ordinary experience.

The alleged impunity of the Styrians, in the habitual use of arsenic, may be occasionally quoted to explain the detection of the poison in a dead body, or a motive for its purchase; but no scientific witness who has seen anything of the operation of arsenic in this country can allow these statements to influence his opinion of its effects on human beings. Those who profess to believe in this practice, would be among the last to make a trial of it, either on their own persons, or among their friends.

The only form in which I have known the question of habit to be seriously raised in medical jurisprudence is this: whether, while the more prominent effects of poison are thereby diminished, the insidious or latent effects on the constitution are at the same time counteracted. The answer is of some importance in relation to the subject of life insurance; for the concealment of the practice of opium-eating by a person whose life was insured, has already given rise to an action, in which medical evidence on this subject was rendered necessary. As a general principle, we must admit that habit cannot altogether counteract the insidious effects of poisons; and that the practice of taking them is liable to give rise to disease or to impair the constitution.

Influence of Idiosyncrasy.—Idiosyncrasy differs from habit; it does not, like habit, diminish the effect of a poison; for it is not commonly found that any particular state of body is a safeguard against the effects

of these powerful agents. Some constitutions are observed to be much more affected than others by certain poisons; thus opium, arsenic, mercury, lead, and antimony are substances of this description, and this difference in their effect is ascribed to idiosyncrasy. Sir R. Christison mentions a remarkable instance in which a gentleman unaccustomed to the use of opium, took nearly an ounce of laudanum without any effect. ("On Poisons," 33.) This form of idiosyncrasy is very rare. Certain substances generally reputed harmless, and indeed, used as articles of food, are observed to affect some persons like poisons. This is the case with pork, certain kinds of shell-fish, and mushrooms. There may be nothing poisonous in the food itself; but it acts as a poison in particular constitutions—whether from its being in these causes a poison *per se*, or rendered so by changes during the process of digestion, it is difficult to say. The subject of idiosyncrasy is of importance in a medico-legal view, when symptoms resembling those of poisoning follow a meal consisting of a particular kind of food. In such a case, without a knowledge of this peculiar condition, we might hastily attribute to poison, effects which were really due to another cause. It would appear that in some instances idiosyncrasy may be acquired—*i. e.*, a person who, at one period of his life, had been in the habit of partaking of a particular kind of food without injury, may find at another period that it will disagree with him. When pork has been disused as an article of diet for many years, it cannot always be resumed with impunity. In cases in which the powers of life have become enfeebled by age, the susceptibility of the system to poisons is increased; thus aged persons may be killed by comparatively small doses of arsenic and opium. Cases of acquired idiosyncrasy are very rare; it appears to be, if we may so apply the term, a congenital condition. There are, however, certain diseases which appear to confer a power of supporting large and even poisonous doses of some substances. Very large doses of opium have been taken without producing dangerous symptoms by persons laboring under tetanus and hydrophobia. This condition is called *tolerance*. It has been witnessed in diseases of the lungs, in reference to the use of antimonial medicines.

Classification of Poisons.—Poisons may be divided into two great classes, according to their mode of action on the system; namely, IRRITANTS and NEUROTICS. Irritant poisons manifest their action chiefly on the stomach and bowels, while the special action of Neurotic poisons is to affect directly one or more parts of the nervous system. The Neurotic poisons admit of a subdivision into Cerebral, Spinal, and Cerebro-spinal, according to whether the poisonous substance affects directly the brain, the spinal marrow, or both of these organs. By some poisons the heart appears to be primarily affected. These may form a subdivision of cerebro-cardiac poisons.

Irritants.—The irritants are possessed of these common characters: When taken in ordinary doses, they occasion speedily violent vomiting and purging. The symptoms are either accompanied or followed by pain in the throat, stomach and bowels. The peculiar effects of the poison are manifested chiefly on these organs, which, as their name implies, they irritate and inflame. Many substances belonging to this class of poisons

possess corrosive properties; such as the strong mineral acids, caustic alkalies, bromine, corrosive sublimate and others. These, in the act of swallowing, are commonly accompanied by an acrid or burning taste, extending from the mouth down the gullet to the stomach. Some irritants do not possess any corrosive action—of which we have examples in arsenic, the poisonous salts of baryta, carbonate of lead, and cantharides; these are often called pure irritants. They exert no destructive chemical action on the tissues with which they come in contact; they simply irritate and inflame them.

Difference between Corrosive and Irritant Poisons.—As a result of the action of *corrosive* poisons, symptoms are commonly manifested immediately, because mere contact produces the destruction of a part. In the action of the purely *irritant* poisons, the symptoms are generally more slowly manifested, rarely showing themselves until at least half an hour has elapsed from the time of swallowing the substance. Of course, there are exceptions to this remark; for sometimes irritants act speedily, though rarely with the rapidity of corrosive poisons. It is important in a practical view, to ascertain whether, in an unknown case, the poison which a person, requiring immediate treatment, may have swallowed, is irritant or corrosive. This may be commonly determined by a knowledge of the time at which the symptoms appeared after the suspected substance was taken. We may thus often easily distinguish between a case of poisoning from arsenic and one from corrosive sublimate. There is also another point which may be noticed. As the corrosive substance exerts a decidedly chemical action, an examination of the mouth and throat may enable us in some cases to solve the question.

It has already been stated that there are many irritant poisons which have no corrosive properties, but every corrosive may act as an irritant. Thus the action of corrosive sublimate is that of an irritant poison, as, while it destroys some parts of the coats of the stomach and intestines, it irritates and inflames others. So again most corrosive poisons may lose their corrosive properties by dilution with water, and then they act simply as irritants. This is the case with the mineral acids and bromine. In some instances, it is not easy to say whether an irritant poison possesses corrosive properties or not. Thus oxalic acid acts immediately, and blanches and softens the mucous membrane of the mouth and throat, but I have not met with any decided marks of chemical corrosion produced by it in the stomach or viscera. Irritant poisons, for the most part, belong to the mineral kingdom; and they may be divided into the *Non-metallic* and *Metallic* irritants. There are a few derived from the animal and vegetable kingdoms; but these, if we except cantharides, are not often employed criminally. Some of the gases likewise belong to the class of irritant poisons.

NEUROTICS.—Neurotic poisons act upon the nerve centres and upon the nervous system generally, and their operation is confined chiefly to the brain and spinal marrow. Either immediately or some time after the poison has been swallowed, the patient suffers from headache, giddiness, numbness, paralysis, stupor, and in some instances, convulsions. They have not an acrid burning taste like the corrosive irritants; and they rarely give rise to vomiting or purging. When these symptoms

follow the ingestion of the poison into the stomach, the effect may be generally ascribed either to the form or quantity in which it has been taken, and the mechanical effect on the stomach thereby produced, or to the poison being combined with some irritating substance, such as alcohol. The pure *Narcotics*, or *Cerebral poisons*, are not found to irritate or inflame the stomach and bowels.

Notwithstanding the well-defined boundary thus apparently existing between these two classes of poisons, it must not be supposed that the substances arranged in each class always act in the manner indicated. Some irritants have been observed to affect the brain or the spinal marrow, and this may be either a primary or a secondary consequence of their action. Arsenic and oxalic acid, although classed as irritants, have in some instances given rise to symptoms closely resembling those of narcotic poisoning—namely, coma, paralysis and tetanic convulsions. In a case of poisoning by arsenic, which occurred to Dr. Morehead, of Bombay, the symptoms of narcotism were so strongly marked, that it was believed at first the man had taken a narcotic. (“Med. Gaz.” vol. 43, p. 1055.) I have met with a case of poisoning by arsenic in which there was paralysis of the limbs, with an entire absence of purging, during the eight days that the deceased survived. On the other hand, in a case of poisoning by a large dose of opium, there was an absence of the usual symptoms of cerebral disturbance, and the presence of others resembling those of irritant poisoning—namely, pain and vomiting. Thus, then, we must not allow ourselves to be misled by the idea that the symptoms are always clearly indicative of the kind of poison taken. The narcotic or cerebral poisons are few in number, and belong to the vegetable kingdom. Some of the poisonous gases possess a narcotic action.

Narcotico-irritants. (Spinal and Cerebro-spinal Poisons.)—Poisons belonging to this class have, as the name implies, a compound action. They are chiefly derived from the vegetable kingdom. At variable periods after they have been swallowed, they give rise to vomiting and purging, like irritants, and sooner or later produce stupor, coma, paralysis and convulsions, owing to their effects on the brain and spinal marrow. In the state of vegetables, as leaves, seeds, or roots, they possess the property, like irritants, of irritating and inflaming the stomach and bowels. As familiar examples we may point to nux vomica, monkshood, hemlock, and poisonous mushrooms. This class of poisons is very numerous, embracing a large variety of well-known vegetable substances; but they rarely form a subject of difficulty to a medical practitioner. The fact of the symptoms occurring after a meal at which some suspicious vegetables may have been eaten, coupled with the nature of the symptoms themselves, will commonly indicate the class to which the poison belongs. Some of these poisons have a hot acrid taste; others, like aconite or monkshood, produce a sense of numbness or tingling, while others again have an intensely bitter taste, as nux vomica, strychnia, veratria, and picrotoxia. Strychnia may be regarded as a pure spinal poison.

CHAPTER V.

EVIDENCE OF POISONING IN THE LIVING BODY.—ACTION OF POISONS INCREASED OR DIMINISHED BY DISEASE.—SYMPTOMS CONNECTED WITH FOOD OR MEDICINE.—SEVERAL PERSONS ATTACKED SIMULTANEOUSLY.—EVIDENCE FROM THE DETECTION OF POISON IN THE FOOD, ETC.

WE now proceed to consider the evidence of poisoning in the *living* body. To the practitioner, the diagnosis of a case of poisoning is of great importance, as by mistaking the symptoms produced by a poison for those arising from natural disease, he may omit to employ the remedial measures which have been found efficacious in counteracting its effects, and thus lead to the certain death of the patient. To a medical jurist, a correct knowledge of the symptoms furnishes the chief evidence of poisoning, in those cases in which persons are charged with the malicious and unlawful administration of poison. The symptoms produced during life constitute also an important part of the evidence in those instances in which a poison proves fatal. At present, however, we will suppose the case to be, that poison has been taken, and the patient survives. Most toxicological writers have laid down certain characters whereby it is said symptoms of poisoning may be distinguished from those of disease.

1. *In poisoning, the symptoms appear suddenly, while the individual is in health.*—It is the common character of most poisons, when taken in the large doses in which they are usually administered with criminal intent, to produce serious symptoms, either immediately, or within a very short period after they have been swallowed. Their operation, under such circumstances, cannot be suspended, and then manifest itself after an indefinite interval; although this was formerly a matter of universal belief, and gave rise to many absurd accounts of what was termed *slow poisoning*.

The symptoms of poisoning by nicotina, prussic acid, oxalic acid, or the salts of strychnia, appear immediately, or generally within a very few minutes after the poison has been swallowed. In an exceptional case, in which the dose of prussic acid was small, and insufficient to produce death, the poison was supposed by the patient not to have begun to act until after the lapse of fifteen minutes. ("Ed. Med. and Surg. Journ.," vol. 59, p. 72.) The symptoms caused by arsenic and other irritants, and, indeed, by all poisons generally, are commonly manifested in from half an hour to an hour. It is rare that the appearance of symptoms is protracted for two hours, except under certain peculiar states of the system. It is said that some narcotic poisons, such as the poisonous mushrooms, may remain in the stomach twelve or twenty-four hours without giving rise to symptoms; and this is also affirmed to be the case with some animal irritants, such as decayed meat; but with regard to

the first point, it has been shown by Dr. Peddie that mushrooms have produced symptoms in half an hour; and a case has fallen under my own observation, in which the symptoms from noxious animal food came on within as short a time after the meal, as is commonly observed in irritant poisoning by mineral substances. In some cases of poisoning by phosphorus, no symptoms have occurred until after the lapse of several hours.

Influence of Disease.—A diseased state of the body may render a person comparatively unsusceptible of the action of certain poisons, while in other instances it may increase their action, and render them fatal in small doses. In dysentery and tetanus a person may take, without being materially affected, a quantity of opium sufficient to kill an adult in average health. In mania, cholera, hysteria, and delirium tremens, large doses of opium may be borne with comparative impunity (p. 85). In a case of hemiplegia, a woman *æt.* 29, took for six days, three grains of strychnia daily without injurious consequences—the dose having been gradually raised (“*Gaz. Méd.*” Mai, 1845);—while one grain of strychnia is commonly regarded as a fatal dose to a healthy adult. In a case of tetanus, Dupuytren gave as much as two ounces of opium at a dose (60 grammes), without serious consequences. (Flandin “*Traité des Poisons*,” vol. 1, p. 231.) It has also been remarked that persons affected with tetanus are not easily salivated by mercury. The morbid state appears to create the power of resisting the ordinary effects of poisons. (“*Colles’s Lectures*,” vol. 1, p. 77.) The effect of certain diseases of the nervous system, as well as of habit, either in retarding the appearance of symptoms, or in blunting the operations of a poison, it is not difficult to appreciate; there are cases which can present no practical difficulty to a medical jurist. On the other hand, in certain diseased states of the system, there may be an increased susceptibility of the action of poison. Thus, in those persons who have a disposition to apoplexy, a small dose of opium may act more quickly and prove fatal. In a person laboring under inflammation of the stomach or bowels, there would be an increased susceptibility of the effects of arsenic, antimony, or other irritants. In debility from any cause, these mineral substances would also act injuriously, even in ordinary doses. Antimony is a most powerful depressant, and might, by its effect on the heart, cause death by syncope.

The influence of disease in increasing the operation of poison, has been noticed in cases of diseased kidney (granular degeneration), in which small doses of mercury have produced severe salivation, leading to exhaustion and death. In diseases of the lungs affecting aged persons, opium in medicinal doses, has been observed to exert a poisonous action. The effect of the drug appears to be intensified by the disease. This observation applies equally to morphia. Chloroform vapor in ordinary quantity has been found to produce fatal effects, in cases in which there was latent disease of the heart, or of the coronary arteries of this organ. A fatty condition of the muscular tissue leading to great feebleness of the heart’s action, appears to be highly favorable to death by syncope, under the use of chloroform.

A knowledge of these facts is of importance in reference to charges of

malapraxia when death has arisen from ordinary, or extraordinary doses of medicines, administered to persons laboring under disease. In such cases, another mode of treatment should be substituted, or a smaller dose than usual given, and its effects carefully watched. In some instances, however, full and large doses of powerful drugs have been recklessly given, and when a fatal result has followed, there has been a strong disposition to refer death to the supposed disease, of which, however, sometimes no trace could be found in the body. An experienced physician, well acquainted with pathological anatomy, informs me that since the use of chloroform has become general, and deaths under its use are not unfrequent, a fattiness and flabbiness of the muscular structure of the heart has been sought for and almost universally found! The fatal result has not been attributed to its real cause—the imprudent or careless administration of chloroform, but to some minute structural changes revealed by the microscope in the substance of the organ.

Symptoms appear during a state of health.—Symptoms of poisoning may manifest themselves in a person while in a state of *perfect health*, without any apparent cause. This rule is, of course, open to numerous exceptions, because the person on whose life an attempt has been made, may be actually laboring under disease; and under these circumstances the symptoms may be so obscure as to disarm all suspicion. When poison is secretly exhibited in medicine, a practitioner is very liable to be deceived, especially if the disease under which the person is laboring is of an acute nature, and is attended by symptoms of disorder in the alimentary canal. Several cases of poisoning have occurred in which arsenic was criminally substituted for medicine, and given to the parties while laboring under a disorder of the bowels. We are, however, justified in saying, with respect to this character, that when in a previously healthy person, violent vomiting and purging occur suddenly and without any assignable cause, such as pregnancy, disease, or indiscretion of diet, to account for them, there is strong reason to suspect that irritant poison has been taken. When the person is already laboring under disease, we must be especially watchful on the occasion of any sudden change in the character or violence of the symptoms, unless such change can be easily accounted for on common, or well-known medical principles. In most cases of criminal poisoning, we meet with alarming symptoms without any obvious or sufficient natural causes to explain them. The practitioner will, of course, be aware that there are certain diseases which are liable to occur suddenly in healthy people, the exact cause of which may not at first sight be apparent; therefore this criterion is only one out of many on which a medical opinion should be founded.

2. *In poisoning the symptoms appear soon after a meal, or soon after some kind of food or medicine has been taken.*—This is by far the most important character of poisoning in the living body. It has been already stated that most poisons begin to operate within an hour after they have been swallowed; and although there are few exceptions to this remark, yet they occur under circumstances easily to be appreciated by a practitioner. Thus, then, it follows that, supposing the symptoms under which a person is laboring, to depend on poison, the substance has most probably been swallowed, either in food or medicine, from half

an hour to an hour previously. It must be observed, however, that causes may occur in which the poison has not been introduced by the mouth. Oil of vitriol and other corrosive liquids have been thrown up the rectum in injections, and have thus caused death; the external application of arsenic, corrosive sublimate and cantharides to ulcerated surfaces has destroyed life. In one case, arsenic was introduced into the vagina of a female, and she died in five days under all the symptoms of arsenical poisoning. (Schneider, "Ann. der. ges. Staatsarzneikunde," i. 299.) Such cases are rare, but, nevertheless, the certainty that they have occurred, where their occurrence could hardly have been anticipated, shows that in a suspicious case a practitioner should not deny the fact of poisoning, merely because it may be proved that the person could not have taken the poison in the usual way, by the mouth. Again, persons may be destroyed by vapors of ether, chloroform, prussic acid, or other powerful volatile poisons, introduced into the body through the lungs. Such a mode of suicide or murder might disarm suspicion, from the fact of no noxious material being found in the stomach.

Let us suppose, however, the circumstances to have been such that these secret means of destruction could not have been resorted to, and that the poison is one of those most commonly selected by a murderer, such as arsenic, tartar emetic, oxalic acid, or corrosive sublimate, then we may expect that this character of poisoning will be made evident to us, and that something must have been *swallowed* by the patient shortly before the alarming symptoms appeared. By observations attentively made, it may be in our power to connect the appearance of the symptoms with the use of a particular article of food, and thus indirectly lead to the detection of a criminal. Supposing that many hours have passed since food or medicine was taken by the patient, without any effect ensuing, it is probable that the symptoms are due to natural causes, and not to poison.

When symptoms resembling those of poisoning speedily follow the ingestion of food or medicine, there is, however, reasonable ground for suspicion; but caution should be observed in drawing inferences, since the most extraordinary coincidences sometimes present themselves. In the case of *Sir Theodosius Boughton*, who was poisoned by his brother-in-law Donellan, in 1781, the fact of alarming symptoms coming on in *two minutes* after the deceased had swallowed what was supposed to be a simple medical draught, was a most important part of the evidence against the prisoner. There is no doubt that laurel-water had been substituted for the medicine by the prisoner, and that this had caused the symptoms which preceded death. The practice of substituting poisonous mixtures for medical draughts or powders is by no means unusual, although it might be supposed to indicate a degree of refinement and knowledge not commonly to be found among criminals. Medical practitioners are thus apt to be imposed upon, and the following case, related by a deceased judge, will serve as a caution: An apothecary prepared a draught, into which another person put poison, intending thereby to destroy the life of the patient for whom the medicine was prescribed. The patient, not liking the taste of the draught, and thinking there was something suspicious about it, sent it back to the apothecary, who, know-

ing the ingredients of which he had composed it, and wishing to prove to his patient that he had done nothing wrong, drank it himself, and died from the effects. He was thus the unconscious agent of his own death; and although the draught was intended for another, the party who poisoned it was held guilty of murder. This case contains a warning to medical witnesses. It is not unusual, on trials for poisoning, when the poison is conveyed through medicine, to find a medical witness offering to swallow his own draught in a court of law, in order to furnish a convincing practical illustration of the innocence of the medicine! It need hardly be observed that an exhibition of this kind is never required of a medical witness. If any doubt be raised of the innocent properties of a draught or powder, a chemical analysis of its contents will be far more satisfactory, and attended with no kind of risk to the practitioner. In one instance within my knowledge, a medical man, who had unconsciously put forty grains of strychnia into a mixture in place of oxide of bismuth, nearly lost his life by taking a small quantity of it. The first dose of the mixture destroyed his patient in half an hour, but when called to her, he felt so confident that he had made no mistake, that in the presence of her relatives he removed the cork from the bottle and swallowed a small quantity. He suffered from symptoms of poisoning with strychnia, and recovered with difficulty. He thus furnished the best evidence of his mistake.

On the other hand, the occurrence of symptoms resembling those produced by poisoning, soon after food or medicine has been taken, may be a pure coincidence. In such a case poison is always suspected by the vulgar; and it will be the duty of a medical jurist to guard against the encouragement of such a suspicion, until he has strong grounds to believe it to be well founded. No public retraction or apology can ever make amends for the injury which may in this way be inflicted on the reputation of another; for those who hear the accusation may never hear the defence. In all such cases, a practitioner may entertain a suspicion, but, until confirmed by facts, he should avoid *expressing* it, or giving it publicity. When death is not a consequence, it is difficult to clear up such cases, except by the aid of a chemical analysis; but this, as we know, is not always applicable. If death ensue, the real cause is usually apparent, and a suspicion of poisoning is thus often removed by an examination of the body. (See Chapter on SUFFOCATION.)

3. *In poisoning, when several partake at the same time of the same food or medicine mixed with poison, all suffer from similar symptoms.*—This character of poisoning cannot always be procured: but it furnishes good evidence of the fact when it exists. Thus, supposing that after a meal made by several persons from the same dish, only one suffers, the suspicion of poisoning is considerably weakened. The poisoned article of food may be detected by observing whether they who suffer under any symptoms of poisoning have partaken of one particular solid or liquid in common. In a case of accidental poisoning at a dinner-party, a medical man who was present observed that those who suffered had taken port-wine only; the contents of the bottle were examined, and found to be a saturated solution of arsenic in wine. In general, considerable reliance may be placed upon this character, because it is improb-

able that any common cause of disease should suddenly attack with violent symptoms of a similar character, many healthy persons at the same time, and within a short period after having partaken of food together. We must beware of supposing that, when poison is really present, all will be attacked with precisely similar symptoms; because there are many circumstances which may modify their nature and progress. In general, that person who has partaken most freely of the poisoned dish will suffer most severely; but even this does not always follow. There is a well-known case, recorded by Bonnet, where, among several persons who partook of a dish poisoned with arsenic, they who had eaten little and *did not vomit*, speedily died; while others, who had partaken largely of the dish, and had in consequence vomited freely, recovered.

It was just now remarked, that there was no disease resembling poisoning which is likely to attack several healthy persons at the same time and in the same manner. This is undoubtedly true as a general principle, but the following case will show that mistakes may occasionally arise even under these circumstances. It occurred in London during the prevalence of the malignant cholera in 1832. Four of the members of a family, living in a state of great domestic unhappiness, sat down to dinner in apparently good health: some time after the meal, the father, mother, and daughter were suddenly seized with violent vomiting and purging. The evacuations were tinged with blood, while the blueness of the skin, observed in cases of malignant cholera, was absent. Two of these persons died. The son, who was known to have borne ill-will against his father and mother, and who suffered no symptoms on this occasion, was accused of having poisoned them. At the inquest, however, it was clearly shown by the medical attendant, that the diseased persons had really died of malignant cholera, and there was no reason to suspect that any poison had been administered to them. In this instance, it will be perceived that symptoms resembling those of irritant poison, appeared suddenly in several individuals in perfect health, and shortly after a meal. We hereby learn that the utility of any rules for investigating cases of poisoning depends entirely on the judgment and discretion with which they are applied to particular cases.

It is well to bear in mind, in conducting these inquiries, that symptoms resembling those produced by irritant poison, may be sometimes traced to *food* itself. Meat, rendered unwholesome by disease or decay, pork, bacon, sausages, cheese, and bread, as well as certain kinds of shell-fish, may give rise to symptoms of poisoning, and even cause death. Such cases may be regarded as poisoning by animal or vegetable irritants. All the characters above described as indicative of poisoning, may be observed, and the difficulty of forming an opinion is often increased by the fact that some of the persons attacked may have previously partaken of the same kind of food without inconvenience.

4. *The discovery of poison in the food taken, or in the matters vomited.*—One of the strongest proofs of poisoning in the living subject, is the detection of poison by chemical analysis, or, if of a vegetable nature, by a microscopical examination, either in the food taken by the person laboring under its effects, or in the matters vomited, or, after the lapse of a few hours, in the urine. The evidence is of course more satisfactory

when the poison is detected in the matters vomited, or in the urine, than in the food, because this will show that it has really been taken, and it will readily account for the symptoms. If the vomited matters have been thrown away, we must examine the food of which the patient may have partaken. Should the results in both cases be negative, and no trace of poison be found in the urine, it is probable that the symptoms were due to disease.

In investigating a case of poisoning in a living subject, a medical jurist must remember, that poisoning is sometimes *feigned*, and at others *imputed*. It is easy for an artful person to put poison into food, as well as to introduce it into the matters vomited or discharged from the bowels, and to accuse another of having administered it. There are few of these accusers who go so far as to swallow poison under such circumstances, as there is a great dread of poisonous substances among this class of criminals; and it will be at once apparent, that it would require a person well versed in toxicology, to feign a series of symptoms which would impose upon a practitioner at all acquainted with the subject. In short, the difficulty reduces itself to this: What inference can be drawn from a chemical detection of poison in food? All that a medical man can say is, whether poison is or is not present in a particular article of food; he must leave it to the authorities of the law to develop the alleged attempt at administration. If the poison has been actually administered or taken, then we should expect to find that the person had suffered from the usual symptoms. The absence of these symptoms would be a strong fact against the alleged administration. The detection of poison in the matters vomited, affords no decisive proof that it has been swallowed, except under two circumstances: 1. When the accuser has previously labored under the usual symptoms of poisoning, in which case there can be no feigning, and the question of imputation is a matter to be established by general evidence. 2. When the matters are actually vomited into a *clean vessel*, in the presence of the medical attendant himself, or of some person on whose testimony perfect reliance can be placed. The detection of absorbed poison in the *urine* furnishes a clear proof that poison has been taken, that it has passed into the blood, and has been subsequently eliminated.

When a medical man is called to a case of suspected poisoning, it is necessary that he should know to what points he ought to give his attention. It is very proper that every effort should be made by him to save life when the individual is living; but while engaged in one duty, it is also in his power to perform another (supposing the case to be one of suspected criminal poisoning), namely, to note down many circumstances which may tend to detect the perpetrator of a crime. There is no person so well fitted to observe these points as a medical man; but it unfortunately happens, that many facts important as evidence are often overlooked. The necessity for observing and recording them is not perhaps generally known. A medical man need not make himself officious on such occasions, but he would be unmindful of his duty as a member of society, if he did not aid the cause of justice by extending his scientific knowledge to the detection of crime. It is much to the credit of the medical profession, that the crime of murder by poisoning—a form of

death from which no caution or foresight can protect a person, is so frequently brought to light, by the announcement of suspicious facts of a medical nature to magistrates and coroners; and on several occasions the highest compliments have been passed by judges on medical men who have been thus indirectly the means of bringing atrocious criminals to the bar of justice.

The following appear to me to be the principal points which demand the attention of a medical jurist in all cases of suspected poisoning: 1. With respect to

Symptoms.—1. The time of their occurrence—their nature. 2. The exact period at which they were observed to take place after a meal, or after food or medicine had been taken. 3. The order of their occurrence. 4. Whether there was any remission or intermission in their progress or whether they continued to become more and more aggravated until death. 5. Whether the patient had labored under any previous illness. 6. Whether the symptoms were observed to recur more violently after a particular meal, or after any particular kind of food or medicine. 7. Whether the patient has vomited:—the vomited matters, if any (especially those *first* ejected), should be procured; their odor, color, and acid or alkaline reaction noted, as well as their quantity. 8. If none be procurable, and the vomiting has taken place on the dress, furniture, or floor of the room—then a portion of the clothing, sheet, or carpet may be cut out and reserved for analysis:—if the vomiting has occurred on a deal floor, a portion of the wood may be scraped or cut out:—or if on a stone pavement, then a clean sponge soaked in distilled water may be used to remove any traces of the substance. The vessel in which vomited matters have been contained will often furnish valuable evidence, since heavy mineral poisons fall to the bottom or adhere to the sides. 9. Endeavor to ascertain the probable nature of the food or medicine last taken, and the exact *time* at which it was taken. 10. Ascertain the nature of *all* the different articles of food used at a meal. 11. Any suspected articles of food, as well as the vomited matters, should be sealed up as soon as possible in clean glass vessels, labelled, and reserved for analysis. 12. Note down in their own words all explanations voluntarily made by persons present, or who are supposed to be concerned in the suspected poisoning. 13. Whether more than one person partook of the food or medicine:—if so, whether all these persons were affected, and how? 14. Whether the same kind of food or medicine had been taken before by the patient or other persons, without ill effects following.

[As has been shown by the author, it is not possible from the *symptoms alone* to do more than merely infer the probability of a poison, inasmuch as there is no poison that possesses absolutely characteristic symptoms; (if so, there would be no necessity for a chemical analysis). The great uncertainty on this point should suggest extreme caution to “experts” in testifying to the presence of poisons from the *symptoms alone*. In the late (second) trial of Mrs. Wharton, 1873, at Annapolis, on the charge of attempting to poison Eugene Van Ness, the State’s medical witnesses undertook to testify to the presence of tartar-emetic, among the various alleged poisons, merely from certain symptoms—

nausea, vomiting, and general debility—which were quite the reverse of the symptoms that these same “experts,” along with others, swore to in the former Wharton trial, as constituting a main ground for their opinion as to the presence of antimony in the stomach of Gen. Ketchum! In this second case, all the symptoms were shown by the defence to be logically ascribable to disease. Moreover, no antidotes were administered, and no means employed to get rid of the alleged poison; no examination was made of the suspected food or drinks, and no search for it either in the vomited matters, or in the urine!—R.]

CHAPTER VI.

EVIDENCE OF POISONING IN THE DEAD BODY.—PERIOD AT WHICH POISONS PROVE FATAL.—CHRONIC POISONING.—APPEARANCE PRODUCED BY THE DIFFERENT CLASSES OF POISONS.—REDNESS OF THE MUCOUS MEMBRANE MISTAKEN FOR INFLAMMATION.—ULCERATION AND CORROSION.—SOFTENING.—PERFORATION OF THE STOMACH FROM POISON AND DISEASE.

SUPPOSING that the person is dead, and we are required to determine whether the case is one of poisoning or not, we must, in the first instance, endeavor to ascertain all the particulars which have been considered in the last chapter, as indicative of poisoning in the living body. Should the deceased have died from poison, the circumstances of the attack, and the symptoms preceding death ought to correspond with the characters already described; and in these investigations, it is well to bear in mind the following rule: There is no one symptom or pathological condition which is peculiar to poisoning; but at the same time there is probably no disease which presents *all* those characters which are met with in a special case of poisoning. The additional evidence to be derived from the *death* of a person, may be considered under the following heads:—

1. *The time at which death takes place after the first occurrence of symptoms.*—This question requires examination, because the more common poisons, when taken in fatal doses, generally cause death within definite periods of time. By an attention to this point, we may, in some instances, be enabled to negative a charge of poisoning, and in others to form an opinion of the kind of poison which has been taken. In a court of law, a medical practitioner is often required to state the usual *period of time* within which poisons prove fatal. It is to be observed that, not only do poisons differ from each other in this respect, but the same substance, according to the form or quantity in which it has been taken, may differ in the rapidity of its action. A large dose of prussic acid, *i. e.*, from half an ounce to an ounce, may destroy life in less than two minutes. In ordinary cases of poisoning by this substance a person dies, *i. e.*, all signs of life have commonly ceased, in from ten to twenty minutes; if he survives half an hour, there is some hope of recovery. In

the cases of seven epileptics, accidentally poisoned by a similar dose of this acid in one of the Parisian hospitals, the first died in about twenty minutes, the seventh survived three-quarters of an hour. Oxalic acid, one of the most energetic of the common poisons, when taken in a dose of from half an ounce to an ounce, may destroy life in from ten minutes to an hour; if the poison is not perfectly dissolved when swallowed, it is a longer time in proving fatal. The strong mineral acids, in poisonous doses, destroy life in about eighteen or twenty-four hours. Arsenic, under the form of arsenious acid (white arsenic), operates fatally in from eighteen hours to three or four days. It has, however, in more than one instance, killed a person in two hours. Opium, either as a solid or under the form of laudanum, commonly proves fatal in from six to twelve hours; but it has been known, in several instances, to destroy life in less than three hours; they who survive the effects of this poison for twelve hours are considered to have a fair chance of recovery. This must be understood to be merely a statement of the average results, as nearly as we are warranted in giving an opinion; but the medical jurist will of course be aware that the fatal period may be protracted or shortened, according to all those circumstances which have been elsewhere stated to affect the actions of poisons.

There are various forms which this question may assume. It may be said that the death of a person, alleged to have taken poison, has occurred either too rapidly or too slowly to justify a suspicion of poisoning. The following case will serve as an illustration: A woman of the name of *Russell* was tried and convicted at the Lewes Summer Assizes, in 1826, for the murder of her husband, by poisoning him with arsenic. The poison was detected in the stomach; but the fact of poisoning was disputed by some medical witnesses, for this among other reasons, that the deceased had died *three* hours after the only meal at which the poison could have been administered to him. The authority of Sir A. Cooper and others was cited to show that according to their experience, they had never known a case of poisoning by arsenic to have proved fatal in less than seven hours. This may be admitted, but, at the same time, there was sufficient authority on the other side to establish that some cases had actually proved fatal in three or four hours. So far as this objection was concerned, the prisoner was properly convicted. In reference to the medical question raised at this trial, I may observe that two distinct cases have since occurred in which the individuals died certainly within *two hours* after taking arsenic; and several instances have been reported, in which death has taken place in from three to four hours after the administration of this poison. It seems extraordinary in the present day, that any attempt should have been made by a professional man to negative a charge of criminal poisoning upon so weak a ground as this; but this opinion was expressed many years ago, when the facts connected with poisoning were but little known. It is quite obvious that there is nothing, so far as we know, to prevent arsenic from destroying life in an hour, or even within a shorter period. A case will be hereafter related, in which death took place from arsenic probably within twenty minutes. These matters can be settled only by a careful observation of numerous

cases, and not by any *à priori* reasoning, or by a limited individual experience.

In all instances of sudden death there is generally a strong tendency on the part of the public to suspect poisoning. They never can be brought to consider that persons may die a natural death *suddenly*, as well as slowly; or, as we shall presently see, that death may really take place slowly, and yet be due to poison. This prejudice continually gives rise to the most unfounded suspicions of poisoning, and at the same time, leads to cases of chronic or slow poison being frequently mistaken for natural disease. One of the means recommended for distinguishing narcotic poisoning from apoplexy or disease of the heart, is the difference in the rapidity with which death takes place. Thus, apoplexy or disease of the heart may prove fatal either instantly, or within an hour. The only poisons likely to operate with such fatal rapidity are prussic acid or nicotina. Poisoning by opium is commonly protracted for five or six hours. This poison has never been known to destroy life instantaneously, or within a few minutes. Thus, then, it may happen that death will occur with such rapidity as to render it impossible, under the circumstances, to attribute it to narcotic poison.

Chronic poisoning.—When a poison destroys life rapidly, it is called a case of *acute* poisoning to distinguish it from the *chronic* form, *i. e.*, in which death takes place slowly. Chronic poisoning is a subject which has of late frequently required medico-legal investigation. Most poisons, when their effects are not rapidly manifested, owing either to the smallness of the dose, or to timely treatment, are capable of slowly undermining the powers of life, and killing the patient by producing emaciation and exhaustion. This is sometimes observed in the action of arsenic, corrosive sublimate, and tartarized antimony, but it has been remarked also in cases of poisoning by the mineral acids and caustic alkalies. Death is here an indirect consequence; in poisoning by the acid or alkalies, either stricture of the gullet is induced, or the lining membrane of the stomach is destroyed, and the process of digestion impaired, a condition which leads to exhaustion and death. The time at which these indirect effects may prove fatal, is of course liable to vary. A person has been known to die from a stricture of the gullet, brought on by sulphuric acid, *eleven months* after the poison was swallowed; and there is no reason to doubt that instances may occur of a still more protracted nature. In cases of *chronic poisoning* there is sometimes great difficulty in assigning death exclusively to the original action of the poison, since the habits of life of the person, a tendency to disease, and other circumstances, may have occurred either to accelerate or produce a fatal result. To connect a stricture of the gullet proving fatal, with the effects of poisoning by a mineral acid, it would be necessary to show that there was no tendency to this disease before the acid was administered; that the symptoms appeared soon after the first effects of the poison went off; that these symptoms continued to become aggravated until the time of death; and lastly, that there was no other cause to which death could with any probability be referred. These remarks apply equally to the secondary fatal effects of any poison, such, for instance, as the salivation occasionally induced by corrosive sublimate, and the exhaustion and de-

pression which are caused by tartarized antimony, when the acute symptoms of poisoning by these substances have passed away.

The characters of chronic poisoning have of late years acquired a special interest for the medical jurist. There is a difficulty about them which no accuracy of observation or judgment can surmount. The poison or poisons, if found in the dead body at all, must necessarily exist in fractional parts of a grain. This alone will be sufficient to create a doubt whether death has been caused by the poison, although it is quite consistent with medical experience that a person may die from chronic poisoning, and little or none of the poison be found in the body after death. In the case of Mrs. James (*Reg. v. Winslow*), not more than the tenth part of a grain was found in the whole of the tissues of the body; in the case of Isabella Banks (*Reg. v. Smethurst*), the quantity was greater than this, but less than a grain altogether; while in the case of Mrs. Peters, of Yeovil, examined by Mr. Herapath, *none* was found in the body, although this chemist had extracted a quantity of antimony as sulphide from the urine of deceased, in less than nine days before death. In this case Dr. Garland had also found antimony in the evacuations during life, and had referred the intermittent irritation of the stomach and bowels, from which deceased had suffered, to the secret use of this mineral. The jury returned a verdict that deceased had died from disease, and that death was accelerated by some irritant. ("Lancet," August 4th, 1860, p. 119.) On some recent trials for poisoning (*Reg. v. William Palmer*, C. C. C., 1856), it has been a contested scientific question, whether a person can die from poison, and no trace of the poison remain in the body. Mr. Herapath's evidence in Mrs. Peters's case not only now proves the affirmative, but goes to show that antimony may act fatally and be entirely eliminated from the system in about a week. ("Med. Times and Gaz.," Aug. 25, Sep. 12, and 29, 1860, pp. 190, 271, 317.)

His results have been lately confirmed by the researches of Dr. Morton, U. S. This physician has performed many experiments on the elimination of antimony when given in small doses so as to produce the effects of chronic poisoning. No traces of the metal were found in the urine four days after the last dose, and the quantity eliminated had been decreasing daily up to that time ("Am. Journ. Med. Sci.," January, 1879).

2. *Evidence from appearances in the body.*—One of the chief means of determining whether a person had died from poison is an examination of the body after death. In relation to *external* appearances, there are none indicative of poisoning upon which we can safely rely. It was formerly supposed that the bodies of persons who were poisoned, putrefied more rapidly than those of others who had died from natural disease; and evidence for or against poisoning was at one time derived from the external appearance of the body. This is now known to be an error; the bodies of persons poisoned are not more rapidly decomposed, *cæteris paribus*, than those of others who have died a sudden and violent death from any cause whatever.

Irritant poisons act chiefly upon the stomach and intestines, which they irritate, inflame, and corrode. We may likewise meet with all the

consequences of inflammation, such as softening, thickening, ulceration, perforation, or gangrene. Sometimes the coats of the viscera are thickened, at other times thinned and softened, by the action of an irritant.

Neurotic (Cerebral and Spinal) poisons do not commonly leave any well-marked appearances in the body. The stomach and intestines present no unnatural changes. There may be greater or less fulness of the vessels of the brain and spinal marrow, as well as of their membranes, but even this is often so slight as to escape notice, unless attention be particularly directed to those organs. Effusion of blood is rarely found.

It is important to bear in mind, that both Irritants and Neurotics may destroy life without leaving any appreciable changes in the body. To such cases as these the remarks about to be made do not apply. The proofs of poisoning must, in such exceptional cases, be procured entirely from other sources. Any evidence derivable from the appearances in the body of a person poisoned, will be imperfect unless we are able to distinguish them from those analogous changes often met with as the results of ordinary disease. These are confined to the mucous membrane of the stomach and bowels. They are redness, ulceration, softening and perforation. Each of these conditions may depend upon disease, as well as upon the action of the irritant poisons.

Redness.—It is a main character of the irritants to produce, as a result of inflammation, redness of the mucous or lining membrane of the stomach and small intestines. This redness, when first seen, is usually of a deep crimson color, becoming brighter by exposure to air. It may be diffused over the whole mucous membrane; at other times it is seen in patches, dots, or lines (*striæ*), spread irregularly over the surface of the stomach. It is sometimes met with at the smaller, but more commonly at the larger end of this organ, and again we occasionally find the folds or prominences only of the mucous membrane presenting this red or inflamed appearance. Redness of the mucous membrane may, however, be due to gastritis or gastroenteritis as a result of disease; and in order to assign the true cause of the inflammation, it will be necessary to have an account of the symptoms preceding death, or some chemical proofs of the existence of irritant poison in the contents of the stomach, or in the tissues of the body.

In the healthy state, the mucous membrane of the stomach is pale and white, or nearly so, except during digestion, when it is slightly reddened; and some observers have remarked that a slight redness has often remained in the stomachs of those who have died during the performance of the digestive process. When in contact with the spleen or liver, after death, the stomach is apt to require a deep livid color from the transudation of blood; and it is well known that the bowels acquire a somewhat similar color from the gravitation of blood which always takes place after death. None of these appearances are likely to be mistaken for the action of an irritant poison.

There is an important class of cases in which redness of the mucous membrane of the stomach is found after death, not dependent on the action of the poison, or an easily assignable cause. These cases, owing to their being so little known, and involved in much obscurity, deserve

the attention of the medical jurist, since the appearances closely resemble those produced by irritant poison. A person may die without suffering from any symptoms of disordered stomach; but on an inspection of the body, a general redness of the mucous membrane of this organ will be found, not distinguishable from the redness which is so commonly seen in arsenical poisoning. Several cases of this kind have occurred at Guy's Hospital: and drawings which have been made of the appearance presented by the stomach are preserved in the Museum collection.

The redness of the lining membrane of the stomach, in cases of poisoning, is so speedily altered by putrefaction, when circumstances are favorable to this process, as frequently to render it impossible for a witness to speak with any certainty upon its cause. Putrefactive infiltration from the blood contained in the adjacent viscera and muscles will give a reddish-colored appearance to a stomach otherwise in a healthy condition. Great dispute has arisen respecting the length of time during which redness of the stomach produced by an irritant will be recognizable, and easily distinguishable from putrefactive changes. It is sufficient to say, that no certain rules can be laid down on the subject: it must be left to the knowledge and discretion of the witness. I have distinctly seen the well-marked appearances of inflammation produced by arsenic in the stomach and duodenum in an exhumed body twenty-eight days after interment (*Reg. v. Jennings*, Berks Lent Ass., 1845); and in another instance, referred to me by Mr. Lewis, the coroner for Essex, in August, 1846, the reddened state of the mucous membrane, in a case of arsenical poisoning was plainly perceptible on removing a layer of arsenic, *nineteen months* after interment. (See, on this question, a case of suspected poisoning by Orfila, "*Annales d'Hyg.*," 1839, vol. 1, p. 127.) If, however, there should be a reasonable doubt respecting the cause of redness, and no poison is detected, it would be unsafe to rely upon this appearance alone as evidence of poisoning.

Ulceration.—In irritant poisoning, the stomach is occasionally found ulcerated; but this is, comparatively speaking, a rare occurrence. In such cases the mucous membrane is removed in small distinct circular patches, under the edges of which the poison (arsenic) may be found. Ulceration of the stomach is a more common result of disease, than of the action of poison. As a consequence of disease, it is very insidious, going on often for weeks together, without giving any indication of its existence, except perhaps slight gastric disturbance with occasional nausea, vomiting, and loss of appetite. In this case, the ulceration is commonly seen in small circumscribed patches. It is worthy of remark, as a means of distinction, that ulceration has never been known to take place from arsenic or any irritant poison, until symptoms indicative of irritant poisoning have occurred. In ulceration from disease, the mucous membrane is commonly only reddened in the neighborhood of the ulcer. In ulceration from poison, the redness is generally diffused from other parts of the stomach, as well as over the duodenum and small intestines. A case, however, occurred in Guy's Hospital, some years ago, in which, with a small circular patch of ulceration near the cardiac opening, the whole mucous membrane was red and injected; but this singular condition of the stomach, so closely resembling the effects of an irritant

poison, was unaccompanied by any marked symptoms of irritation during life. The history of a case previous to death will thus commonly enable us to determine to what cause the ulceration found, may be due.

Care must be taken to distinguish ulceration from *corrosion*. Ulceration is a vital process: the substance of a part is removed by the absorbents, as a simple result of inflammation. Corrosion, on the other hand, is a chemical action; the parts are removed by the immediate contact of the poison; they are decomposed; their vitality is destroyed, and they combine with the corrosive matter itself. Ulceration requires time for its establishment, while corrosion is either an instantaneous, or a very rapid effect.

Softening.—The coats of the stomach are not unfrequently found so soft as to yield and break down under very slight pressure; and this may be the result either of poisoning, of some spontaneous morbid change in its structure during life, or of the solvent action of the gastric juice after death. As this condition of the stomach, when caused by poison, is produced by those substances only which possess corrosive properties, it follows that in such cases, traces of their action will be perceived in the mouth, throat, and gullet. In softening from disease, the change will be confined to the stomach alone, and it is commonly found only at the cardiac or greater end of the organ. When softening is really caused by an irritant poison, it is generally attended by other striking and unambiguous marks of its operation. Softening is not to be regarded as a common character of poisoning; it is only an occasional appearance. I have met with an instance in which the coats of the stomach were considerably hardened by sulphuric acid. Softening can never be inferred to have proceeded from poison, unless other well-marked changes are present, or unless the poison is discovered in the softened parts. The stomachs of infants have been frequently found softened from natural causes: such cases could not be mistaken for poisoning, since the history of them during life, the want of other appearances indicative of poisoning, and the total absence of poison from the viscera would prevent such a suspicion from being entertained.

Perforation.—The stomach may become perforated, either as a result of poisoning, or disease.

Perforation from poisoning may arise: 1, from corrosion; 2, from ulceration. The perforation by *corrosion* is by far the most common variety of perforation from poisoning. It is occasionally witnessed when the strong mineral acids have been taken, especially sulphuric acid; the stomach, in such cases, is blackened and extensively destroyed, the aperture is large, the edges are rough and irregular, and the coats are easily lacerated. The acid escapes into the abdomen, and may be readily detected there by chemical analysis. The perforation from *ulceration*, caused by irritant poison (arsenic), is but little known. There are but few instances on record. In a great number of poisoned subjects examined during many years past at Guy's Hospital, not a single case has occurred. It must, then, be looked upon as a rare occurrence in cases of irritant poisoning.

Perforation from disease.—This is by no means an unusual condition. Many cases of this disease will be found reported elsewhere. (“Guy's

Hosp. Rep." No. 8.) It is invariably fatal when it proceeds so far that the contents of the stomach escape into the abdomen; but sometimes the stomach becomes glued to the pancreas or other organs during the ulcerative process, and the person may recover. Several instances of this kind of adhesion have been met with in inspections. The symptoms from perforation commonly attack a person suddenly, while apparently enjoying perfect health. Hence these cases may be easily mistaken for those of irritant poisoning. The principal facts observed with regard to this formidable disease are the following: 1. It often attacks young women from eighteen to twenty-three years of age. 2. The preceding illness is extremely slight; sometimes there is mere loss of appetite, or a capricious appetite, with uneasiness after eating. 3. The attack commences with a sudden and most severe pain in the abdomen, generally soon after a meal. In irritant poisoning the pain usually comes on gradually, and slowly increases in severity. 4. Vomiting, if it exists at all, is commonly slight, and is chiefly confined to what is swallowed. There is no purging; the bowels are generally constipated. In irritant poisoning the vomiting is usually severe, and purging seldom absent. 5. The person dies commonly in from eighteen to thirty-six hours; this is also the average period of death in the most common form of irritant poisoning, *i. e.* by arsenic; but in no case yet recorded has arsenic caused perforation of the stomach within twenty-four hours; and it appears probable that a considerable time must elapse before such an effect could be produced by this, or any irritant. 6. In perforation from disease, the symptoms and death are clearly referable to peritonitis. 7. In the perforation from disease the aperture is commonly of an oval or rounded form, about half an inch in diameter, situated in or near the lesser curvature of the stomach, and the edges are smooth. The outer margin of the aperture is often blackened, and the aperture itself is funnel-shaped from within outwards, *i. e.*, the mucous coat is the most removed, and the outer or peritoneal coat the least. The coats of the stomach, round the edge of the aperture, are usually thickened for some distance; and when cut they have almost a cartilaginous hardness. These characters of the aperture will not alone indicate whether it is the result of poisoning or disease; but the absence of poison from the stomach, with the want of other characteristic marks of irritant poisoning, would enable us to say that disease was the cause. Besides, the history of the case during life would materially assist us in our judgment. The great risk in all these cases is, that the effects of disease may be mistaken for those of poisoning; for we are not likely to mistake perforation caused by irritant poison for the result of disease. Notwithstanding the well-marked difference above described, it is common to meet with cases of imputed poisoning, where death has really occurred from peritonitis following perforation. I have been required to examine several cases of this kind; one of them will be found elsewhere recorded. ("Guy's Hosp. Reports," Oct. 1850, page 226.) In another the body was exhumed after several months' burial, and the stomach was found perforated from disease in the usual situation. [Intestinal perforation sometimes occurs from sudden strain or effort, or external violence.—II.]

Spontaneous or gelatinized perforation.—The stomach is occasionally subject to a spontaneous change, by which its coats are softened, and give way generally at the cardiac or greater end. As the effusion of the contents of the organ, in such a case, never gives rise to peritoneal inflammation, and no symptoms occur prior to death to indicate the existence of so extensive a destruction of parts, it is presumed to be a change in the dead body, and the coats of the stomach are supposed to undergo a process of solution or digestion. It is commonly attributed to the solvent action of the gastric-juice,—the spleen diaphragm, and other viscera being sometimes softened. Dr. Wilks, who has for many years conducted the inspections at Guy's Hospital, found this post-mortem or cadaveric perforation of the stomach so rare a condition, that he did not meet with it once in five hundred cases. In two cases in which it was observed, one patient had died from albuminuria and the other from head-affection; but in neither of these could there be found any peculiarities regarding their food, the time of the last meal, or the state of the bodies to account for the spontaneous destruction of the coats of the stomach. (For remarks on this subject by Dr. Budd, see "Med. Gaz.," vol. 39, p. 895.) In January, 1845, I met with an instance of this perforation in a child between two and three years of age. It was seized with convulsions, became insensible, and died twenty-three hours afterwards. After death, the greater end of the stomach was found destroyed to the extent of three inches; and the edges were softened and blackened. There was no food in the stomach, and nothing had passed into the organ for thirty-two hours before death! It was therefore impossible to ascribe death to the perforation, or the perforation to poison. (For a full account of this case, see "Med. Gaz.," vol. 36, p. 32.) An inspection of the body, with a general history of the case, will commonly suffice to remove any doubt in forming an opinion whether the extensive destruction so commonly met with, has or has not arisen from poison. Thus, in a cadaveric perforation, the aperture is generally situated in that part of the stomach which lies to the left of the cardia; it is very large, of an irregular form, and ragged and pulpy at the edges, which have the appearance of being scraped. The mucous membrane of the stomach is not found inflamed. There is occasionally slight redness, with dark brown or almost black lines (*striæ*) in and near the dissolved coats, which have an acid reaction. It can only be confounded with perforation by the action of corrosives; but the well-marked symptoms during life, and the detection of the poison after death, together with the changes in the throat and gullet, will at once indicate the perforation produced by corrosive poison.

[It is vitally important that the post-mortem examiner should be qualified by practical training and experience, as well as judgment, to understand fully and distinctly the appearances referred to in the foregoing chapter. We fear, however, that the responsibility is too often assumed in this country by practitioners who have no right or reason to pretend to the indispensable qualifications, and whose ignorance and indiscretion might easily be exposed by a well-directed cross-examination. The case of John Hendrickson, Jr., convicted, on altogether insufficient medical testimony, of poisoning his wife with aconite, affords a lamentable in-

stance of this kind of perversion of medico-legal investigation. (See "Am. Journ. Med. Sci.," October, 1855, p. 447, for an able and justly severe review of the medical evidence in this trial by Dr. C. Lee.) But it is not only in the observation of the anatomical appearances, even when fully competent to recognize their true characters, that we must exercise the greatest caution. The evidence afforded by the sight and smell of matters in the alimentary canal and other portions of the body, although sometimes very significant, should always be subjected to the closest scrutiny. Odor and color are proverbially uncertain; and although the recognition of peculiarities of form is less liable to error, yet when these are so minute as to require the employment of the microscope to determine them, the faculty of discriminating is at present restricted to an extremely limited circle of observers.—H.]

[For a full discussion of the importance and relative value of the *chemical analysis* for establishing the proof of poisoning, see "Taylor On Poisons," Chap. XI. From the foregoing remarks, it will easily be understood how dangerous it would be, in a case involving life and death to rely either upon *symptoms* or the *autopsic appearances*, or even upon both, as affording positive proof of poison. A leading American authority, uses the following judicious language upon this point: "These verifications (the symptoms and the autopsy) once established, and a harmony between the lesions shown by the physician or physiologist, and the substance discovered by chemical analysis being settled, then, *and only then*, can the conclusion be reached that death was due to poison." (Wharton and Stillé's "Med. Juris.," 1873, vol. ii. p. 287.) We would not, however, be understood to say that the chemical evidence is always *indispensable* for proving the administration of poison. In certain cases, for good reasons, this chemical detection is impossible; but in these exceptional instances, the other two factors—the symptoms and the anatomical lesions—as likewise the *moral* circumstances of the case, should be so positive and unequivocal, as to leave no shadow of doubt.—R.]

IRRITANT POISONS.

CHAPTER VII.

SULPHURIC ACID, OR OIL OF VITRIOL.—NITRIC ACID, OR AQUA FORTIS.—
HYDROCHLORIC ACID.—SYMPTOMS.—APPEARANCES AND ANALYSIS.

SULPHURIC ACID, OR OIL OF VITRIOL.

Symptoms.—When this poison is swallowed in a concentrated form, the symptoms produced come on either *immediately*, or during the act of swallowing. There is violent burning pain, extending through the throat and gullet to the stomach, and the pain is often so severe that the body is bent. There is an escape of gaseous and frothy matter, followed by retching and vomiting, the latter accompanied by the discharge of shreds of tough mucus, and of a liquid of a dark coffee-ground color, mixed with blood. The mouth is excoriated; the lining membrane and surface of the tongue white, or resembling soaked parchment; in one instance the appearance of the mouth was as if it had been smeared with white paint. After a time, the membrane acquires a gray or brownish color: the mouth is filled with a thick viscid substance consisting of saliva, mucus, and the corroded membrane; this renders speaking and swallowing difficult. If the poison has been administered by a spoon, or the phial containing it has been passed to the back of the throat, the mouth may escape the chemical action of the acid. A medical witness must bear this circumstance in mind, when he is called to examine an infant suspected to have been poisoned by sulphuric acid. Around the lips and on the neck may be found spots of a brown color from the spilling of the acid and its action on the skin. There is great difficulty of breathing, owing to the swelling and excoriation of the throat and larynx, and the countenance has from this cause a bluish or livid appearance; the least motion of the abdominal muscles is attended with increase of pain. The stomach is so irritable, that whatever is swallowed is immediately ejected, and the vomiting is commonly violent and incessant. The matters *first* vomited generally contain the poison; they are acid, and if they fall on a limestone pavement there is effervescence; if on colored articles of dress, the color is sometimes altered to a red or yellow, or it is entirely discharged, and the texture of the stuff destroyed; on a black cloth dress, the spots produced by the concentrated acid are reddish-brown, and remain moist for a considerable time. After a time there is exhaustion, accompanied by great weakness; the pulse becomes

quick, small, and feeble, the skin cold, mottled, and covered with clammy sweat. There is generally great thirst, with obstinate constipation of the bowels; should any evacuations take place, they are commonly either of a dark-brown or leaden color, in some instances almost black, arising from an admixture of altered blood. There are sometimes convulsive motions of the muscles, especially those of the face and lips. The countenance, if not livid from obstructed respiration, is pale, expressive of great anxiety and intense suffering. The intellectual faculties are quite clear, and death usually takes place very suddenly, in from eighteen to twenty-four hours after the poison has been taken. *Sulphate of indigo* produces similar symptoms. The vomited matters are, however, bluish-black.

Appearances after death.—The marked effects of this poison are not always observed in the stomach; they may be confined to the region of the throat and windpipe. In an inspection of the body, the whole course of the alimentary canal from the mouth downwards, should be examined; since in recent or acute cases it is in the throat and gullet that we generally obtain strong evidence of the action of a corrosive poison. The discovery of the usual marks of corrosion in these parts is always highly corroborative of the signs of poisoning found in the stomach. During the inspection, the examiner must not omit to notice any spots on the skin produced by the action of the acid: these are commonly of a dark-brown color, and are situated about the mouth, lips, and neck.

The appearances met with in the body of a person who has died from the effects of this acid vary, according to whether death has taken place rapidly or slowly. Supposing the case to have proved rapidly fatal, the membrane lining the mouth may be found white, softened, and corroded. The mucous membrane of the throat and gullet is commonly found corroded, having a brown-black, or ash-gray color, and blood is effused in patches beneath it. The corroded membrane of the gullet is occasionally disposed in longitudinal folds, portions of it being partly detached. The stomach, if not perforated, is collapsed and contracted. On laying it open, the contents are commonly of a dark-brown or black color and of a tarry consistency, being formed in great part of mucus and altered blood. The contents may or may not be acid, according to the time the patient has survived, and the treatment which has been adopted. On removing them, the stomach may be seen traversed by black lines, or the whole of the mucous membrane may be stained black, or of a dark-brown color. On stretching the coats, the red color indicative of inflammation may be sometimes seen in the parts beneath, or surrounding the blackened portions. When the stomach is perforated, the coats are softened, and the edge of the aperture is commonly black and irregular. In removing the stomach, the opening is liable to be made larger by the mere weight of the organ. The contents do not always escape; but when this happens, the surrounding parts are attacked by the poison. In a case which occurred at Guy's Hospital, the spleen, the liver, and the coats of the aorta were found blackened and corroded by the acid, which had escaped through the perforation. In some rare cases, the lining membrane of the aorta has been found strongly reddened. When a person has survived for eighteen or twenty hours, traces of corrosive and inflammatory action may be

found in the small intestines. In one case the mucous membrane of the ileum was corroded. The interior of the windpipe, as well as of the bronchial tubes, has also presented marks of the local action of the acid. The acid has thus destroyed life without reaching the stomach. A remarkable instance in which the poison penetrated into and destroyed both lungs has been reported by Sir William Gull. (See "Med. Gaz.," vol. 45, p. 1102.) It is important for a medical witness to bear in mind, that the mouth, throat, and gullet are not always found in the state above described. Dr. Ogle met with a case in which the membrane of the tongue was but slightly affected. The man had swallowed a large dose of the acid, and had died in nine hours. ("Med. Times and Gazette," April 21, 1860.)

Fatal dose.—The dangerous effects of sulphuric acid appear to arise rather from its degree of concentration, than from the absolute quantity taken. The quantity actually required to prove fatal, must depend on many circumstances. If the stomach is full when the poison is swallowed, the action of the acid may be spent on the food and not on the stomach; and a larger quantity might then be taken than would suffice to destroy life if the organ were empty. The smallest quantity which is described as having proved fatal was in the following case: Half a teaspoonful of concentrated sulphuric acid was given to a child about a year old by mistake for castor oil. The usual symptoms came on, with great disturbance of breathing; and the child died in twenty-four hours, the quantity here taken could not have exceeded *forty drops*. ("Med. Gaz.," vol. 29, p. 147.) It is, however, doubtful whether this small quantity would have proved fatal to an adult. The smallest fatal dose which Sir R. Christison states he has found recorded, is *one drachm*; it was taken in mistake by a young man, and killed him in seven days. (Op. cit., 162.) Even when diluted, the acid will destroy life rapidly. A man swallowed, on an empty stomach, six drachms of the strongest acid diluted with eighteen drachms of water. He suffered from the usual symptoms, and died in two hours and a half. ("Med. Times and Gaz.," 1863, vol. 1, p. 183.)

The average period at which death takes place in cases of acute poisoning by sulphuric acid is from eighteen to twenty-four hours. The shortest case recorded occurred to M. Rapp. A man, æt. 50, swallowed three ounces and a half of concentrated sulphuric acid; he died in *three-quarters of an hour*. ("Gazette Médicale," Dec. 28, 1850.) On the other hand, there are numerous instances reported in which the poison proved fatal from secondary causes, at periods varying from one week to several months.

Chemical analysis.—If the acid is in a pure state and *concentrated*, it possesses these properties: 1. Wood, sugar, or other organic matter plunged into it, is speedily carbonized or charred, either with or without the application of heat. 2. When boiled with wood, copper-cuttings, or mercury, it evolves fumes of sulphuric acid; this is immediately known by the odor, as well as by the acid vapor first rendering blue, and then bleaching, starch-paper dipped in a solution of iodic acid. 3. When mixed with an equal bulk of water, great heat is evolved—nearly 200° F., in a cold vessel.

Sulphuric acid when *diluted* does not carbonize organic substances.

One test only is required for its detection, namely, a solution of a salt of baryta—either the *nitrate*, or *chloride of barium*. Having ascertained by test-paper that the suspected liquid is acid, we add to a portion of it a few drops of nitric acid, and then a solution of nitrate of baryta. If sulphuric acid is present, a dense white precipitate of sulphate of baryta will fall down; this is insoluble in all acids and alkalies. If the precipitate is collected, dried, and heated to redness in a small platinum crucible, or in a folded piece of platinum foil, with five or six parts of charcoal powder, it will, if a sulphate, be converted into sulphide of barium. To prove this, we add to the calcined residue hydrochloric acid, at the same time suspending over it a slip of filtering paper moistened with a solution of acetate of lead. If the precipitate obtained is a sulphate, the gas evolved will be sulphuretted hydrogen, known by its odor and by its turning a salt of lead of a brown color. The cyanide or ferrocyanide of potassium may be used as a reducing agent in place of charcoal, in a proportion about equal to that of the sulphate of baryta. The experiment may then be performed in a reduction-tube in the flame of a spirit lamp. On breaking the glass and laying the incinerated residue on paper or card wetted with a salt of lead, a brown stain indicative of sulphide of lead is produced.

[A very delicate test for *dilute* sulphuric acid is *veratria*, which when introduced in small quantity, and evaporated to dryness, produces a beautiful purple color.—R.]

In liquids containing organic matters.—If sulphuric acid is mixed with such liquids as porter, coffee, or tea, the process for its detection is substantially the same, the liquid being first rendered clear by filtration. The precipitated sulphate of baryta, if mixed with organic matter, may be purified by boiling it in strong nitric acid; but this is not commonly necessary, as the reduction of the dried precipitate may be equally well performed with the impure as with the pure sulphate. Some liquids, such as vinegar, porter, and most wines, generally contain sulphuric acid or a sulphate, but the acid is in small proportion; therefore, if there is an abundant precipitation, there can be no doubt, *cæteris paribus*, that free sulphuric acid has been added to them. Should the liquid be thick and viscid, like gruel, it may be diluted with water, and then boiled with the addition of a little acetic acid. For the action of the barytic test, it is not necessary that the liquid should be absolutely clear, provided it is not so thick as to interfere mechanically with the precipitation of the sulphate of baryta. So far with regard to articles administered, or of which the administration has been attempted. This process may be applied to the examination of matters *vomited* and of the *contents of the stomach*,—care being taken to separate the insoluble parts by filtration, or by the process of *dialysis*, before adding the test. The coats of the stomach should be cut up, and then boiled in distilled water.

Dialysis.—When the acid is mixed with milk, decomposed blood, and mucus, or other substances, rendering it thick and viscid, it may be readily separated by dialysis; a process which is applicable to the other acid poisons, such as the nitric, hydrochloric, and oxalic. A portion of the acid viscid liquid should be placed in a test tube, about five inches long and one inch in diameter, open at both ends, the neck being securely covered with a layer of thin bladder. The tube is then immersed,

Fig. 1.

Beaker and tube for
the dialysis of liquid
poisons.

mouth downwards, in a beaker containing distilled water (Fig. 1). After some hours the acid will pass through the membrane, and may be detected in the water. This process may be employed as a trial test of the contents of the stomach when they have a strong acid reaction. In thus testing for sulphuric acid it must be remembered that a sulphate, like Epsom salts, may be present in the liquid, and an innocent acid, like vinegar or lemon-juice, may give the acid reaction. To remove any fallacy on this ground, a portion of the liquid tested should be evaporated, and the residue incinerated, when the alkaline sulphate, if present, will be obtained in the form of a dry solid.

Sulphuric acid may be detected on *articles of clothing* by a similar process. The concentrated acid produces brown stains on black cloth; the spots remain damp, and the fibre of the stuff is gradually softened and corroded. The stained portion of cloth should be boiled in water, and the solution filtered and tested with a salt of barium. If any free acid is present, the stained stuff and the solution obtained from it will redden litmus paper. It may thus be detected after the lapse of twenty-seven years.

It is a medico-legal fact of considerable importance, that the contents of a stomach, in a case of poisoning by sulphuric acid, are sometimes entirely free from any traces of this poison, even when it has been swallowed in large quantity. The acid is not commonly found when the person has been under treatment, when there has been considerable vomiting, aided by the drinking of water or other simple liquids, or when he has survived several days. If the case has been under treatment, the acid is either wholly absent, or neutralized by antidotes.

NITRIC ACID, OR AQUA FORTIS.

Symptoms.—When nitric acid is taken in a concentrated state, the symptoms bear a close resemblance to those produced by sulphuric acid. They come on *immediately*, and the swallowing of the acid is accompanied by intense burning pain in the throat and gullet, extending downwards to the stomach; there are gaseous eructations, from the chemical action of the poison, swelling of the abdomen, violent vomiting of liquid or solid matters, mixed with altered blood of a dark brown color, and shreds of yellowish-colored mucus, having a strong acid reaction. The abdomen is generally exquisitely tender; but in one well-marked case of poisoning by the acid, the pain was chiefly confined to the throat; probably the poison had not reached the stomach. The mucous membrane of the mouth is commonly soft and white, after a time becoming yellow, or even brown; the teeth are also white, and the enamel is partially destroyed by the chemical action of the acid. There is great difficulty of speaking and swallowing, the mouth being filled with viscid mucus; the power of swallowing is, indeed, sometimes entirely lost. On opening the mouth, the tongue may be found swollen, and of a citron color; the tonsils are also swollen and enlarged; the teeth are yellow

and corroded. As the symptoms progress, the pulse becomes small, frequent, and irregular, the surface of the body extremely cold, and there are frequent rigors (shivering). The swallowing of liquids increases the severity of the pain, and occasions vomiting. There is obstinate constipation. Death takes place in from eighteen to twenty-four hours, and is sometimes preceded by a kind of stupor, from which the patient is easily roused. The intellectual faculties commonly remain clear until the last.

The *vapor* of this acid is destructive to life. In March, 1854, *Mr. Haywood*, a chemist of Sheffield, lost his life under the following circumstances: He was pouring a mixture of nitric and sulphuric acids from a carboy containing about sixty pounds, when by some accident the vessel was broken. For a few minutes he inhaled the fumes of the mixed acids, but it does not appear that any of the liquid fell over him. Three hours after the accident, he was sitting up and appeared to be in moderately good health. He was then seen by a medical man, and complained merely of some cuts about his hands. He coughed violently. In three hours more there was difficulty of breathing, with increase of the cough. There was a sense of tightness at the lower part of the throat, and the pulse was hard. At times he said he could scarcely breathe. He died eleven hours after the accident. On inspection, there was congestion of the windpipe and bronchial tubes, with effusion of blood in the latter. The heart was flaccid, and contained but little blood; and the lining membrane of the heart and aorta was inflamed. The blood gave a slightly acid reaction with test-paper. The windpipe was not examined. It is very probable the seat of mischief was in this organ, and that the deceased died from inflammatory effusion and enlargement of the parts about the opening of the windpipe. ("Lancet," April 15, 1854, p. 430.) A similar accident occurred to *Mr. Stewart* and to one of the janitors of an educational institution in Edinburgh in March, 1863. They both died from the effects of the acid vapor.

Dr. Bley has recently published an account of three cases of poisoning by these vapors. The symptoms were similar to those above described, and they did not show themselves until some hours after the patients had been removed. One case proved fatal. ("Ann. d'Hyg.," 1879, 1, 276.)

Appearances after death.—Supposing death to have taken place rapidly from the liquid acid, the following appearances may be met with: The skin of the mouth and lips will present various shades of color, from an orange-yellow to a brown. Yellow spots produced by the spilling of the acid may be found about the hands and neck. The membrane lining the mouth is sometimes white, at others of a citron color; the teeth are white, but present sometimes a yellowish color. The throat and windpipe are much inflamed. The lining membrane of the gullet is softened, and of a yellow or brown color, easily detached, often in long shreds. The windpipe is more vascular than usual, and the lungs are congested. The most strongly marked changes are, however, seen in the stomach. When not perforated, this organ may be found distended with gas, its mucous membrane partially inflamed and covered by patches of a yellow, brown, or green color, or it may be even black. Its coats may be so

much softened, as to break down under the slightest pressure. In the duodenum similar changes are found; but in some cases the small intestines have presented no other appearance than that of slight redness. It might be supposed that the stomach would be in general perforated by this corrosive liquid; but perforation has not been often observed. In a case which proved fatal after the long period of six months, there was, at the intestinal end of the stomach, a distinct cicatrix with puckering and hardening of the surrounding mucous membrane, causing a slight contraction of the intestinal orifice. The only other appearance consisted in some dark longitudinal lines on the posterior surface of the lining membrane of the gullet. This had probably been caused by the acid. ("Lancet," Nov. 24, 1860, p. 510.)

The *smallest* quantity of this acid which I find reported to have destroyed life, is about *two drachms*. It was in the case of a boy, aged thirteen; he died in thirty-six hours. Death commonly takes place within twenty-four hours. Sobernheim relates a case of poisoning by nitric acid, which proved fatal in *one hour and three-quarters*. (Op. cit. 402.) This I believe to be the most rapidly fatal instance on record, where the acid acted as a poison. The usual well-marked effects were found in the gullet, stomach, and small intestines. In infants, life may be destroyed by this poison in a few minutes, should it happen to affect the larynx. Tartra records the case of a woman who died from the secondary effects of the acid, *eight months* after having swallowed it. In another case mentioned by Tardieu (op. cit. 220), a woman, aged thirty, died from exhaustion, as a result of stricture of the oesophagus, *two years* after taking the acid.

Chemical analysis. In the simple state.—This acid may be met with either concentrated or diluted. The *concentrated acid* varies in color from a deep orange-red to a light straw-yellow. It may be recognized, 1. By evolving acid fumes when exposed to the air, or when heated. 2. By its staining organic matter yellow or brown, the color being heightened and turned to a reddish tint by contact with caustic alkalies. 3. When mixed with a few copper cuttings, it is rapidly decomposed, a deep red acid vapor is given off, and a bluish colored solution of nitrate of copper is formed. Tin or mercury may be substituted for copper in this experiment. 4. The addition of gold-leaf and a few drops of hydrochloric acid: if nitric acid is present, the gold will be dissolved on warming the mixture. Common aqua fortis (nitric acid) sometimes contains, as impurity, a sufficiency of hydrochloric acid to dissolve gold-leaf by heat.

In the diluted state.—This acid is not precipitated like the sulphuric, by any common reagent, since all its alkaline combinations are soluble in water. 1. The liquid has a highly acid reaction, and (if not too diluted) on boiling it with some copper turnings, red fumes of nitrous acid vapor are given off, the liquid acquiring a blue color at the same time. 2. A streak made on white paper with the diluted acid does not carbonize it when heated; but a scarcely visible yellow stain is left. 3. The liquid is neither precipitated by nitrate of baryta, nor by nitrate of silver. These two last experiments give merely negative results: they serve to show that sulphuric and hydrochloric acids are absent.

In order to detect nitric acid when mixed with water or other liquids, the liquid should be carefully neutralized by potash, and then evaporated slowly to obtain crystals. If the liquid contain nitric acid, these crystals will possess the following characters: 1. They appear in the form of lengthened fluted prisms, which neither effloresce nor deliquesce on exposure. One drop of the solution, evaporated spontaneously on glass, will suffice to yield distinct and well-formed prismatic crystals. This character distinguishes the nitrate of potash from a large number of salts. 2. When moistened with strong sulphuric acid, the powdered crystals slowly evolve a colorless acid vapor. By this test the nitrate is known from every other deflagrating salt. 3. A portion of the powdered crystals should be placed in a small tube, and mixed with their bulk of fine *copper* filings. The mass is then to be moistened with water, and a few drops of strong *sulphuric acid* added. Either with or without the application of a gentle heat, a decomposition immediately ensues, by which red fumes of *nitrous acid* are evolved, recognizable by their color, odor, and acid reaction. In operating on a small quantity of nitrate free from chloride, the crystals may be placed in a watch-glass and mixed with one or two drops of concentrated sulphuric acid and a few copper filings. Invert over this another watch-glass containing a small slip of blue litmus-paper wetted, and a slip of starch-paper moistened with a solution of iodide of potassium. After a longer or shorter interval the litmus will be reddened, and the starch-paper will assume a blue-black color. If the nitrate should be mixed with much chloride, then the power of dissolving leaf-gold, on boiling the dry salt with strong hydrochloric acid, furnishes the best means of detection. 4. We add to the crystals a small portion of gold-leaf and hydrochloric acid; then boil for a few minutes. The gold will either wholly or entirely disappear, if nitric acid or a nitrate is present. Its partial solution will be indicated by a dark purple or brown color on the addition of chloride of tin to the liquid after boiling.

In liquids containing organic matter.—Nitric acid may be administered in such liquids as tea, vinegar, or porter. In this case, besides the acid reaction, there will be a peculiar smell produced by the strong acid when mixed with substances of an organic nature. The application of the usual tests may be here counteracted; thus, unless the quantity of nitric acid in the liquid is considerable, the orange-red fumes of nitrous acid are not evolved on boiling it with copper cuttings. If the liquid is viscid, this viscosity must be destroyed by dilution with water; and in all cases, if any solid or insoluble substances are present, as in the *matters vomited* or *contents of the stomach*, it must be filtered, in order to separate the insoluble portions. The process of *dialysis* may be resorted to. If we succeed in procuring a clear acid liquor, the color may be disregarded. After warming the acid, we should carefully neutralize it with a weak solution of carbonate of potash; it may then be concentrated by evaporation. Paper dipped into this liquid and dried, burns with deflagration, and a few drops on a glass slide will yield crystals possessing those properties which have been described as characteristic of the compound of potash with nitric acid. The crystals so obtained may be colored and impure; but this does not interfere with the

action of the most important test for nitric acid, namely, the mixture of copper filings and sulphuric acid. The crystals may, however, if necessary, be purified by washing them with ether or alcohol. These liquids do not dissolve the nitrate of potash, but will often serve to remove from it the organic matters by which it is colored. When either the nitric acid, or the nitrate into which it has been converted, is mixed with common salt, the copper test cannot be employed. In such a case the gold test will furnish the best evidence. Hydrochloric acid with a small portion of gold-leaf may be added to the dried residue, and the mixture boiled. If nitric acid or a nitrate is present, even in minute proportion, some portion of the gold will be dissolved, a fact demonstrable by the addition of chloride of tin.

Nitric acid may be detected in *stains on clothing*, if recent, by simply boiling the stained cloth in water. The carbonate of potassa must be used when an *acid* liquid is not obtained by boiling the stained cloth in distilled water. A simple method of detecting the acid is to boil at once a piece of the stained cloth with a fragment of leaf-gold and hydrochloric acid. If nitric acid is present in the stain, a portion of the gold will be dissolved.

HYDROCHLORIC ACID. MURIATIC ACID.

This acid, which is also called Muriatic Acid, and is popularly known under the name of Spirit of Salt, is but seldom taken as a poison. In four years, 1863–7, it was the cause of only eight deaths. In the few cases which have been hitherto observed, the *symptoms* and *appearances* have been similar to those caused by nitric acid. The following case will show the nature of the symptoms. A woman swallowed *half an ounce* of concentrated hydrochloric acid, and in three-quarters of an hour, the prominent symptoms were burning pain in the throat and stomach, feeble pulse, cold and clammy skin, retching and vomiting of a brown matter streaked with blood and containing shreds of membrane. There was great exhaustion. The throat became swollen, the patient lost the power of swallowing, and died in eighteen hours. She retained her senses until the last. The *appearances* in the body were as follows: The mucous membrane of the mouth and throat was white, softened, and destroyed in many places by the corrosive action of the acid. The membrane of the gullet was red and inflamed. The back part of the stomach near the pylorus was black, stripped of its mucous membrane (which was generally softened), and marked with black lines. It was not perforated. (“Lancet,” July 16, 1859, p. 59.)

In May, 1878, Dr. Kerby, of Augsburg, met with a case in which a man *æt.* 55 swallowed from a bottle a quantity of this acid somewhat diluted. He hurried away hastily, and some hours after was found lying in great pain. He drank a large quantity of cold water and was able to swallow a little soup. He died twenty-four hours after taking the poison.

On inspection, the mouth, fauces, and *œsophagus* presented no mark of corrosion; the mucous membrane of the *œsophagus* was reddened.

The stomach was neither softened nor perforated, but in a patch of three metres in diameter, the mucous membrane was of a brownish-red color, and blood was extravasated; in other parts it was abraded. The duodenum was intensely red and swollen, and the liver and other organs were congested with dark-colored fluid blood. No free hydrochloric acid was detected in the fluid contents of the stomach. They scarcely reddened litmus paper. There was no doubt that hydrochloric acid had been taken, not in a very concentrated state, and that it was the cause of death. ("Friedreichsblätter der ges. Med." Dec. 1878, p. 443.)

Chemical analysis.—In a *concentrated* state, hydrochloric acid evolves copious fumes. The pure acid is nearly colorless; the commercial acid is of a lemon-yellow color, and frequently contains iron, arsenic, antimony, common salt, and other impurities. When boiled with a small quantity of peroxide of manganese, chlorine is evolved. It does not dissolve gold-leaf until a few drops of nitric acid have been added to it, and the mixture heated. In the *diluted* state, these properties are lost. It may then be recognized by the dense white precipitate which it gives when a solution of nitrate of silver is added to it. This precipitate is insoluble in nitric acid, but soluble in ammonia; it acquires a purple and black color if exposed to light; and when heated, it melts without decomposition, forming a yellowish-colored solid on cooling.

In organic liquids—After proper dilution with distilled water, the liquid should be distilled at a low temperature, and the distillate tested as above. It may also be separated pure by *dialysis*.

Hydrochloric acid, as well as alkaline chlorides, is a natural constituent of the fluids of the alimentary canal. The presence of local chemical changes in the throat and stomach, would show whether the acid had been taken as a poison. If the acid is found only in small quantity, no inference of poisoning can be drawn unless there are distinct marks of its chemical action upon the throat and stomach. It darkens the blood like sulphuric acid, although it has not the same degree of carbonating action on organic matter.

The *stains* produced by this acid on black cloth are generally of a slight reddish color. As the acid is volatile, it may disappear from the stuff. If recent, the acid may be separated by boiling the stuff in water and applying the silver test to the liquid, or by boiling a portion of the stained cloth with leaf-gold and nitric acid. An unstained portion of cloth should be similarly tested for the sake of comparison.

[NITRO-HYDROCHLORIC ACID. AQUA REGIA.]

The general symptoms, effects and post-mortem appearances resemble those of the preceding acid. The test is its solvent power over gold. Its *chlorine* can be detected by the odor evolved, and also by nitrate of silver; its *nitric acid* by the action on copper in the cold.—R.]

CHAPTER VIII.

POISONING BY OXALIC ACID.—SYMPTOMS AND APPEARANCES.—CHEMICAL ANALYSIS.—ACID OXALATE OF POTASH OR SALT OF SORREL.—TARTARIC AND ACETIC ACIDS.

OXALIC ACID.

Symptoms.—If this poison is taken in a large dose, *i. e.* from half an ounce to an ounce of the crystals dissolved in water, a hot burning acid taste is experienced during the act of swallowing it. This is accompanied by a similar sensation extending through the gullet to the stomach. There is sometimes a sense of constriction or suffocation; the countenance is livid, and the surface of the skin soon becomes cold and clammy. Vomiting occurs either immediately or within a few minutes. Should the poison be diluted, there is merely a sensation of strong acidity, and vomiting may not occur until after a quarter of an hour or twenty minutes. In some cases there has been little or no vomiting; while in others, this symptom has been incessant until death. In one case, in which an ounce of the acid was swallowed, the vomiting with pain in the stomach continued until the fifth day, when the man died suddenly (“Lancet,” Nov. 24, 1860, p. 509), and in another in which the poison was much diluted, vomiting did not occur for seven hours. (“Christison,” 221.) The vomited matters are highly acid, and have a greenish-brown or almost black color; they consist chiefly of mucus and altered blood. The patient complains of great pain and tenderness in the abdomen, with a burning sensation in the stomach. There are cold clammy perspirations and convulsions. There is, in general, an entire prostration of strength, so that if the person is in the erect position, he falls; there is likewise unconsciousness of surrounding objects, and a kind of stupor from which, however, the patient may be without difficulty roused. Owing to the severity of the pain, the legs are sometimes drawn up towards the abdomen, or the patient rolls about on the floor or bed. The pulse is small, irregular, and scarcely perceptible; the skin cold and clammy; and there is a sensation of numbness in the limbs with spasmodic breathing. The inspirations are deep, and a long interval elapses between them. Should the patient survive the first effects of the poison, the following symptoms may appear: Soreness of the mouth, constriction, and burning pain in the throat with pain in swallowing, tenderness in the abdomen, and irritability of the stomach, so that there is frequent vomiting, accompanied by purging. The tongue is swollen, and there is great thirst.

The following case is exceptional, from the fact that the symptoms throughout were chiefly referable to the brain. A man took what was

supposed to be a black draught, but it contained oxalic acid instead of Epsom salts. Two hours afterwards he was found in a state of complete coma, but the symptoms set in in a quarter of an hour after he had taken the draught. The man died in five hours, without recovering his consciousness. The only marked appearance on inspection was intense congestion of the brain. ("Lancet," 1872, vol. 2, p. 41.)

Appearances after death.—The mucous membrane of the tongue, mouth, throat, and gullet is softened and commonly white, as if bleached, but it is sometimes coated with a portion of the brown mucous matter discharged from the stomach. This latter organ contains a dark-brown mucous liquid, often acid, and having almost a gelatinous consistency. On removing the contents, the mucous membrane will be seen pale and softened, without always presenting marks of inflammation or abrasion, if death has taken place rapidly. This membrane is white, soft, and brittle, easily raised by the scalpel, and presents the appearance which we might suppose it would assume after having been for some time boiled in water. The small vessels are seen ramifying over the surface, filled with dark-colored blood, apparently solidified within them. The lining membrane of the gullet presents the same characters. It is pale, and appears as if it had been boiled in water, or digested in alcohol; it has been found strongly raised in longitudinal folds, interrupted by patches where the membrane has become abraded. In a case which was fatal in eight hours, the tongue was covered with white specks; the gullet was not inflamed, but the stomach was extensively destroyed, and had a gangrenous appearance. Portions of the mucous membrane were detached, exposing the muscular coat. With respect to the intestines, the upper portion may be found inflamed; but, unless the case is protracted, the appearances in the bowels are not strongly marked.

In a well-marked instance of poisoning by this acid, which is recorded by Dr. Hildebrand, the mucous or lining membrane of the stomach and duodenum was much reddened, although the patient, a girl of eighteen, died in three-quarters of an hour after taking one ounce of the acid, by mistake for Epsom salts. (Casper's "Vierteljahrsschrift," 1853, 3 B. 2 H. page 256.) In a case of poisoning in which two ounces of the acid had been taken, and death was rapid, the coats of the stomach presented almost the blackened appearance produced by sulphuric acid, owing to the color of the altered blood spread over them. In protracted cases, the gullet, stomach, and intestines have been found more or less congested or inflamed. In a case in which an ounce was swallowed, and death occurred on the fifth day, the stomach was slightly congested, and contained a bloody fluid, but the mucous membrane was entire. ("Lancet," Nov. 24, 1860, p. 509.)

I am indebted to Mr. Welch for the following case: A woman, aged 28, swallowed *three drachms* of the crystallized acid. She was found quite dead in *one hour* afterwards. On examining the body, both lungs were observed to be extensively congested, and the heart and large vessels were full of a dark-colored blood. The stomach contained about three-quarters of a pint of a dark-brown fluid, and its lining membrane was generally reddened. The other organs, except the brain, were healthy, and this presented appearances indicative of long-standing dis-

ease. This case is remarkable from the smallness of the dose, the rapidity of death, and the early production of a well-marked redness of the mucous membrane of the stomach. The diseased state of the body may have tended to accelerate death from the poison. In one instance the larynx was found filled with frothy mucus, and the left side of the heart and the lungs were gorged with dark-colored fluid blood. In another, the appearances of sanguineous apoplexy were found in the brain. A person fell dead after retching violently. Apoplexy was supposed to be the cause of death. On an inspection of the body, it was found that a large clot of blood was effused on the brain, and this appeared to account for death satisfactorily. But when the stomach was examined, oxalic acid was detected in it. This poison had been taken, and had produced its usual effects. The deceased had taken it with suicidal intention, and the violent vomiting which it caused had led to death by apoplexy from effusion of blood. ("Lancet," 1863, 1, p. 47.) Without a proper chemical investigation, it is obvious that the real cause of death would have been in this instance overlooked. In a few cases there have been scarcely any morbid appearances produced by this poison.

It is worthy of observation that the glairy contents of the stomach do not always indicate strong acidity until after they have been boiled in water. Oxalic acid does not appear to have a strongly corrosive action of the stomach, like that possessed by the mineral acids. It is, therefore, rare to hear of the coats of the organ being perforated by it. The acid, when in a contracted state, renders the mucous coat soft and brittle, and perforation of the coats may occur either during life or after death as a result of its chemical action. Dr. Wood has recorded the case of a female, æt. 27, found dead, whose death had been obviously caused by oxalic acid, but the quantity taken, and the duration of the case, were unknown. The stomach presented, at its upper and fore part near the cardiac opening, an irregular aperture of a size to admit the point of a finger.

The smallest quantity of this poison which has been known to destroy life is *one drachm* (sixty grains). The boy, æt. 16, took the poison in the solid form, and was found in about an hour insensible, pulseless, and his jaws spasmodically closed. He had vomited some bloody matter; his tongue and lips were unusually pale, but there was no excoriation. He died in eight hours. ("Lancet," Dec. 1, 1855.) Two cases occurred at Guy's Hospital, in each of which half an ounce of oxalic acid had been swallowed. Active treatment was adopted, and both patients recovered. When the dose of oxalic acid is half an ounce and upwards, death commonly takes place within an hour; but there are numerous exceptions to this rapidity of action. Sir R. Christison mentions an instance in which an ounce of oxalic acid killed a girl in thirty minutes; and another in which the same quantity destroyed life in *ten minutes*; but in a third case did not occur until the fifth day. The late Dr. Ogilvy, of Coventry, has reported a case of poisoning by oxalic acid, in which it is probable that death took place within *three minutes* after the poison had been swallowed. The quantity of the acid taken could not be determined.

Chemical analysis. *In the simple state.*—This acid may be met with, either as a solid, or in solution in water. *Solid oxalic acid* crystallizes in long slender prisms, which, when perfect, are four-sided. In this respect, it differs from other common acids, mineral and vegetable. The crystals are unchangeable in air; they are soluble in water and alcohol, forming strongly acid solutions. When heated on platinum foil they melt, and are entirely dissipated in vapor without combustion and without being carbonized. Heated in a close tube, they melt, and the vapor is condensed in a white crystalline sublimate in a cold part of the tube. There should be no residue whatever if the acid is pure; but the commercial acid generally leaves a slight residue of fixed impurity. By this effect of heat, oxalic acid is easily distinguished from those crystalline salts for which it has been sometimes fatally mistaken, namely, the sulphates of magnesia and zinc. These leave white residues in the form of anhydrous salts.

Fig. 2.
Crystals of oxalic acid, magnified
30 diameters.

Tests. 1. *Nitrate of silver.*—When added to a solution of oxalic acid, it produces an abundant white precipitate of oxalate of silver. A solution containing so small a quantity of oxalic acid as not to redden litmus-paper, is affected by this test; but when the quantity of poison is small, it would be always advisable to concentrate the liquid by evaporation before applying it. The *oxalate* of silver is identified by the following properties: It is completely dissolved by cold nitric acid; if collected on a filter, thoroughly dried, and heated on thin platinum foil, it is entirely dissipated in a white vapor with a slight detonation. When the oxalate is in small quantity, this detonation may be observed in detached particles, on burning the filter previously well dried. 2. *Sulphate of lime.*—A solution of oxalic acid is precipitated white by lime-water and all the salts of lime. Lime-water is itself objectionable as a test, because it is precipitated white by several other acids. The salt of lime, which, as a test, is open to the least objection, is the *sulphate*. As this is not a very soluble salt, its solution must be added in rather large quantity to the suspected acid poisonous liquid previously concentrated. A white precipitate of oxalate of lime is slowly formed. This precipitate should possess the following properties: It ought to be immediately dissolved by nitric or hydrochloric acid; and it ought not to be dissolved by the tartaric, acetic, or any vegetable acid.

In organic liquids.—The process is the same, whether it is applied to liquids in which the poison is administered, or to the *matters vomited*, or, lastly, to the *contents of the stomach*. Should the liquid be very acid, we must filter it to separate any insoluble matters; should it not be very acid, the whole may be boiled, if necessary, with distilled water filtered, and concentrated by evaporation. As a trial test we may employ sulphate of copper, or lime-water.

From milk, gruel, coffee, blood, mucus, and other viscid liquids, oxalic

acid is readily separated by the process of *dialysis*. The liquid should be first boiled—the coats of the stomach (cut up) being included, if necessary. The distilled water placed in the outside of the tube will receive the acid. This may be concentrated by evaporation. Prismatic crystals may then be procured, and the silver and lime tests may be applied. Oxalic acid may be completely separated from the boiled and filtered organic liquid by the following process: To the filtered liquid, acidulated with acetic acid, *acetate of lead* should be added until there is no further precipitation; and the white precipitate formed, collected, and washed. If any oxalic acid was present in the liquid, it would exist in this precipitate under the form of *oxalate* of lead. Diffuse the precipitate in water, and pass into the liquid, for about half an hour, a current of sulphuretted hydrogen gas, taking care that the gas comes in contact with every portion of the precipitate. Black sulphide of lead will be thrown down; and with it commonly the greater part of the organic matter mixed with the oxalate of lead. Filter, to separate the sulphide of lead; the filtered liquid may be clear and slightly acid. Concentrate by evaporation; the sulphuretted hydrogen dissolved in the liquid is thereby expelled, and oxalic acid may be ultimately obtained crystallized by slow evaporation in a watch-glass or on a glass-slide, for microscopical observation. If there was no oxalic acid in the precipitate, no crystals will be procured by evaporation. If crystals are obtained they must be dissolved in water, and tested in the manner above directed. Should the organic liquid contain sulphuric acid or sulphates, these should be separated before precipitation by lead is resorted to.

The presence of oxalic acid in an organic liquid may be detected by another method: Place a portion of the liquid containing the poison

Fig. 3.

Crystals of oxalate of lime obtained by dialysis of coffee, containing oxalic acid. Magnified 350 diameters.

in a beaker, and insert in this a tube secured with skin, containing a solution of sulphate of lime. By osmosis, the oxalic acid will penetrate the membrane, and will form inside the mouth of the latter a deposit of crystals of oxalate of lime, known by their octahedral form. (Fig. 3.)

Sometimes the chemical evidence may depend on *stains* on articles of *clothing*. Oxalic acid discharges the color of some dyes, and slowly reddens others; but unless the stuff has been washed, the acid remains in the fabric and may there be detected. It does not corrode or destroy the stuff like mineral acids. In *Reg. v. Morris* (C. C. December, 1866) it was proved that the prisoner had attempted to administer a

liquid poison forcibly to her daughter, a girl aged six years. It was sour in taste, made her lips smart, and caused vomiting. There was dryness of the lips, and inflammation of the lining membrane of the mouth. No portion of the substance administered could be procured, but a crystalline deposit of oxalic acid was obtained from some stains on the dress of the child. The woman was convicted.

As oxalic acid is very soluble in alcohol, this liquid may be occasionally employed for separating it from the contents of the stomach and from many organic compounds. Crystals may be obtained from the alcoholic solution, and these may be purified and tested by the methods already described.

[Oxalic acid cannot be detected in the blood; and if injected into a vessel, it is so readily decomposed that it cannot be recognized even after a few minutes. (Wharton & Stillé's "Med. Juris.," 1873, vol. ii. p. 329.)—R.]

ACID OXALATE OF POTASH, OR SALT OF SORREL.

Symptoms and effects.—The poisonous effects of this salt entirely depend on the oxalic acid which it contains. It is much used for the purpose of bleaching straw and removing ink-stains, and is sold for this purpose under the name of *essential salt of lemons*. Its poisonous properties are not generally known, or no doubt it would be frequently substituted for oxalic acid. Out of three cases of poisoning by this substance, two proved fatal, while in the other the patient recovered. In the case of recovery, a young lady, aged twenty, swallowed an ounce of the salt dissolved in warm water. She was not seen by any one for an hour and a half; she was then found on the floor, faint and exhausted, having previously vomited considerably. There was great depression, the skin cold and clammy, the pulse feeble, and there was a scalding sensation in the throat and stomach. There was also continued shivering. Proper medical treatment was adopted, and she recovered in two days, still suffering from debility and great irritation of the stomach. During the state of depression, it was remarked that the membranes of the eyes were much injected, and the pupils dilated. There was also great dimness of vision. ("Med. Gaz." vol. 27, p. 480.)

This salt destroys life almost as rapidly as oxalic acid itself; and in the symptoms which it produces, it closely resembles that poison. In one case, half an ounce killed an adult in so short a time as *eight minutes*; but probably the fatal effects were in this instance accelerated by the debilitated state of the person who took it. In another case, reported by M. Chevallier, death took place in ten minutes. ("Ann. d'Hyg." 1850, vol. 1, p. 162.) In some instances this poisonous substance has been supplied by mistake for cream of tartar, and has thus caused death.

Chemical analysis.—It is not very soluble in cold water, but its solution may be readily mistaken for that of oxalic acid. 1st, it has an acid reaction; and 2d, it is precipitated by nitrate of silver and sulphate of lime, like oxalic acid; but with the latter test the precipitation is much more copious. It is distinguished from oxalic acid: 1, by its crystals, which, when slowly produced on a glass slide, assume the shape of small rhombic prisms, sometimes grouped in a plumose form; and 2, by heating a portion on platinum foil; while oxalic acid is volatile, the binoxalate leaves an ash, which, when sufficiently heated, is white and alkaline; it may be proved to contain carbonate of potash by its dissolving with effervescence in diluted nitric acid, and forming nitrate of potash.

Tartaric and *Acetic acids* have in some rare cases produced noxious effects on the system. A woman, æt. 58, died at Sheffield in 1877, from taking a quantity of aromatic vinegar.

CHAPTER IX.

POISONING BY ALKALIES AND ALKALINE SALTS.—POTASH, SODA, AND AMMONIA.—NITRATE AND SULPHATE OF POTASH.—CHLORIDE OF BARIUM.

POTASH AND SODA.

Symptoms.—The symptoms produced by potash and soda, when taken in large doses, are similar, so that one description will serve for both. The most common form in which these poisons are met with, is in the state of pearlash (carbonate of potash) and soap-lees (carbonate of soda). The person experiences, during the act of swallowing, an acrid caustic taste, owing to the alkaline liquid, if sufficiently concentrated, excoriating the mucous membrane. There is a persistent sensation of burning heat in the throat, extending down the gullet to the stomach. Vomiting is not always observed; but when it does occur, the vomited matters are sometimes mixed with blood of a dark-brown color, and with detached portions or flakes of mucous membrane; this effect depending on the degree of causticity in the liquid swallowed. The surface is cold and clammy; there is purging, with severe pain in the abdomen, resembling colic. The pulse is quick and feeble. In the course of a short time, the lips, tongue, and throat become swollen, soft, and red. Other symptoms of a more serious kind sometimes show themselves. In April, 1877, a cook in a boarding-school for young ladies put four ounces of washing soda (crude carbonate) into the tea supplied to the pupils. They suffered from severe colicky pains and purging, continuing for several days, with griping pains, loss of appetite, and general feeling of weakness. One young lady, æt. 16, who had partaken freely of the tea, in addition to these symptoms, suffered severely on the fifth day from purpura. There was hæmatemesis, with profuse bleeding from every mucous surface, and spots of ecchymosis on all parts of the skin. She had a tedious and very difficult recovery. It was calculated that she had taken about two drachms of soda.

Period of death.—The most rapidly fatal case of poisoning by alkalies which I have found reported is that of a boy, who died in *three hours* after swallowing three ounces of a strong solution of carbonate of potash. In this respect, the caustic alkalies may destroy life rapidly, like the mineral acids. But death may be also a slow result of these poisons. Thus, in an instance which was communicated to me, a lady swallowed, by mistake, one ounce and a half of the common solution of potash of the shops, which contains about five per cent. of caustic alkali. She recovered from the first symptoms of irritation, but died seven weeks

afterwards, from pure exhaustion, becoming greatly emaciated before her death. The alkali had probably destroyed the lining membrane of the stomach, and had thus impaired digestion.

Appearances after death.—In recent cases there are marks of the local action of the poison on the mucous membrane of the mouth, throat, and gullet. This membrane has been found softened, detached, and inflamed in patches of a deep chocolate color, sometimes almost black. A similar appearance has also been met with in the mucous membrane of the larynx and windpipe. The stomach has had its mucous surface destroyed in patches, and there has been partial inflammation. In one instance, as a result of the action of soda, I found it puckered and blackened. The *quantity* of these alkaline poisons required to destroy life is unknown. The fatal effects depend rather on the degree of concentration of the liquid, than on the absolute quantity of alkali present.

Chemical analysis.—Solutions of POTASH and SODA have a strongly alkaline reaction; they are distinguished from those of their respective carbonates by giving brown precipitates with a solution of nitrate of silver. The CARBONATES, on the other hand, yield a whitish-yellow precipitate. POTASH is known from SODA by the following characters: 1. Its solution, when not too much diluted with water, is precipitated of a canary-yellow color by perchloride of platinum. 2. It is precipitated in granular white crystals, on adding the alkaline liquid gradually to a strong solution of tartaric acid, containing a small quantity of alcohol, and occasionally stirring the mixture. SODA is not precipitated by either of these tests, which will serve equally to distinguish the *salts of potash* from those of soda, if we except the acid oxalate and acid tartrate of potash; these, from being but little soluble in water, are not precipitated. 3. If we neutralize the two alkalies by diluted nitric acid, and crystallize the liquid on a slip of glass, should the alkali be potash, the crystals will have the form of long slender fluted prisms; if soda, of rhombic plates. (Fig. 4.) 4. Potash and its salts are known by their giving a reddish-violet color, while soda and its salts give a bright yellow color to the colorless flame of alcohol.

In liquids containing organic matter.—Such liquids are frothy; they possess an alkaline reaction, a peculiar alkaline odor, and are soapy to the feel. The organic liquid may be evaporated to dryness, and the residue then incinerated in a silver or porcelain capsule; the alkali will be recovered from it in a state of carbonate, by digesting the residuary ash in distilled water.

Fig. 4.

Crystals of nitrate of soda, magnified 30 diameters.

AMMONIA. SPIRIT OF HARTSHORN.

The *vapor* of strong ammonia is poisonous. It may destroy life by producing violent inflammation of the larynx, or of the lungs and air-pass-

ages. It is often injudiciously employed to rouse persons from a fit. A case is on record of an epileptic having died under all the symptoms of croup, two days after the application of strong ammonia to the nostrils. This had been employed to rouse him from a fit.

Symptoms and appearances.—The strong *solution* of ammonia produces symptoms similar to those described in speaking of potash, but as it is much more irritating, it produces a choking sensation, followed by intense heat and burning pain in the throat, gullet, and stomach. Serious injury to the organs of respiration is one of the results of the action of this poison. A gentleman liable to attacks of fainting died in three days, after swallowing a quantity of a liquid administered to him by his son. This liquid, which was at the time believed to be sal volatile, was, in fact, a strong solution of ammonia. The deceased complained immediately of a sensation of choking and strangling in the act of vomiting. Symptoms of difficulty of breathing set in, with other signs of irritation in the throat and stomach. The mucous membrane of the mouth and throat was corroded and dissolved, and it was evident that the liquid had caused great local irritation. The difficulty of breathing was such as to threaten suffocation, and at one time it was thought that an operation must be resorted to. The state of the patient, however, precluded its performance, and he died on the third day. On *inspection*, the viscera presented strong marks of corrosion. The covering of the tongue was softened, and had peeled off; the lining membrane of the air-passages was softened and covered with layers of false membrane, the result of inflammation; and the larger bronchial tubes were completely obstructed by casts or cylinders of this membrane. The lining membrane of the gullet was softened, and at the lower part, near its junction with the stomach, the tube was completely dissolved and destroyed. There was an aperture in the stomach in its anterior wall, about one inch and a half in diameter; the edges were soft, ragged, and blackened, presenting an appearance of solution. The contents of the stomach had escaped. On the inside, the vessels were injected with dark-colored blood, and there were numerous small effusions of blood in various parts of the mucous membrane. The coats were thinned and softened at the seat of the aperture. The blackened and congested appearance of the lining membrane somewhat resembled that which is seen in poisoning by sulphuric or oxalic acid. The mucous matter on the coats of the stomach was feebly *acid*. No poison of any kind was found in the layer of mucus or in the coats. There was not in any part the slightest trace of ammonia, the poison which had caused the mischief. The deceased had lived three days; remedies had been used, and every trace of ammonia had disappeared. The immediate cause of death was an obstruction of the air-tubes, as a result of inflammation, caused by the local irritant action of the liquid; it was quite obvious that a quantity had entered the windpipe. The perforation of the stomach had probably taken place shortly before death, or there would have been marks of peritonitis. The injury to the stomach and gullet would have been sufficient to cause death, even supposing that the liquid had not penetrated into the lungs.

A child, about two years old, swallowed a teaspoonful of strong solution of ammonia. It fell to the floor breathing hurriedly, and became blue

in the face. An hour afterwards, there were white patches on the tongue and cheeks, with congestion of the tonsils and pharynx. There was frequent vomiting, but no blood. Pulse, 164; temperature, 102.8°. The child died the next day. It was unconscious, and there were convulsions at intervals. ("Med. Times and Gaz.," Jan. 1878, p. 35.)

Solution of ammonia applied to the skin acts as a corrosive, and may inflame, blister, or cause the destruction of the parts which it touches. At the Stafford Summer Assizes, 1873 (*Reg. v. Gavan*), a man was convicted of throwing an ammoniacal liquid over the prosecutrix with intent to injure her. It was a liniment containing a strong solution of ammonia. The liquid was thrown in her face, and some portion reached the eyes; but she recovered from the effects. A weak solution acts as an irritant to the skin, while a strong solution causes vesication and a destruction of the part.

Carbonate of ammonia.—The concentrated solution of this salt (sal volatile) is probably more active as a poison than is commonly supposed. A man in a fit of passion, swallowed about five fluidrachms of a solution of sal volatile. In ten minutes, he was seized with stupor and insensibility; but upon the application of stimulant remedies he recovered. He suffered for some time afterwards, from severe irritation about the throat and gullet.

A female, æt. 19, while in a state of unconsciousness, was made to swallow a quantity of hartshorn. She felt a severe pain in the stomach immediately, and in about an hour afterwards she vomited some blood. This vomiting of blood continued for several days. These symptoms were followed by great irritability of the stomach, and the constant rejection of food. There was obstinate constipation of the bowels, with emaciation and loss of strength. She died in about three months from the time at which she had swallowed the alkaline poison. On inspection, the gullet was found healthy; the orifice, at its junction with the stomach, was slightly contracted. The intestinal opening (pylorus) was contracted to the size of a crowquill, and the coats were thickened. On the posterior wall of the stomach there was a dense cicatrix of the size of half a crown, and from this point fibrous bands ramified in various directions. The duodenum and other parts of the intestinal canal were healthy. ("Med. Times and Gazette," Nov. 26, 1853, p. 554.)

Chemical analysis.—Ammonia is distinguished from potash and soda by its pungent odor and entire volatility. The *carbonate of ammonia* may be known from other salts by its alkaline reaction, its odor, and its volatility as a solid; and from pure ammonia by its effervescing on the addition of an acid.

NITRATE OF POTASH. NITRE. SALTPETRE.

There appears to be some uncertainty in the action of this salt, both as to the symptoms and fatal effects on the body. In December, 1863, a man swallowed an ounce of nitre, mixed with water, by mistake for Epsom salts, about nine o'clock in the morning. It produced vomiting with severe pain, but no purging. There was coldness of the surface and lividity of the face. Death took place in three hours. On inspec-

tion, the mucous membrane of the stomach was found highly inflamed, especially towards the middle of the greater curvature, where for several inches it resembled scarlet cloth. The pylorus and duodenum were of a deep crimson color. The peritoneal surface was very vascular, especially over the stomach, the vessels having a vermilion red color, as if they had been injected. The heart and lungs were healthy, the blood was fluid and more florid than natural. The other organs presented no unusual appearance. No analysis was made of the contents of the stomach, but that the nitre was the cause of death no doubt could be entertained, and a verdict was returned accordingly at the coroner's inquest.

Analysis.—For the chemical properties and method of detecting this salt, see page 113.

CHLORATE OF POTASH.

Of late years this compound has been much used in medicine, and it has given rise to several accidents. A child of two and a half years took at once about half an ounce of the chlorate. Severe vomiting followed, which lasted for seven hours, when, in spite of treatment, she died of gastritis. There was profound lethargy, which probably prevented the patient from showing any symptoms of pain. A young man who took the drug in small doses medicinally vomited after each dose. The symptoms from which he suffered were those of gastritis. They ceased on his discontinuing the chlorate. (“Brit. Med. Journ.,” Dec. 28, 1878, p. 966.) In another case, seven drachms were taken at a dose by an adult patient, and caused death. (“Lancet,” Feb. 4, 1879, p. 207.)

SULPHATE OF POTASH.

Symptoms and appearances.—The question whether this should be regarded as an irritant poisonous salt or not, was much debated among members of the profession, in reference to a case which was tried at the Central Criminal Court in October, 1843. (The *Queen v. Haynes*.) The accused had given to the deceased, the night before her death, two ounces of sulphate of potash, dissolved in water; and it was alleged that a fortnight previously to this, she had taken in divided doses, as much as a quarter of a pound of the salt. The woman thought that she was pregnant, but this was disproved by an examination of the body; and it was charged that the prisoner had given her the salt with the intention of causing a miscarriage. After the last dose, she was seized with sickness, and died within a very short time. The stomach was found empty, but highly inflamed; and there was blood effused on the brain. One medical witness referred death to the action of the sulphate as an irritant poison; the other to apoplexy, as an indirect result of the violent vomiting caused by it. The prisoner was acquitted of the charge of murder, but subsequently found guilty of administering the substance with intent to procure abortion. Both of the witnesses admitted that, in small doses, the salt was innocent; but that in the dose of two ounces,

it might produce dangerous effects. Several other fatal cases are recorded. (See "Ann. d'Hygiène," Avril, 1842.)

According to Mr. Mowbray ("Medical Gazette," vol. 33, p. 54), sulphate of potash is much employed in France as a popular abortive. He quotes several instances in which, in large doses, it produced severe symptoms, resembling those of irritant poisoning, and even death. In one case, two drachms acted powerfully; and in another that fell under his own observation, four drachms of the salt administered to a lady after her confinement, had all the effects of an irritant poison.

There is no doubt that the most simple purgative salts may, under certain circumstances, and when given in large doses, destroy life. A case is elsewhere related, in which sulphate of magnesia caused death, and gave rise to a criminal charge in this country. ("ON POISONS," 2d ed. p. 4.) It is said that sulphate of potash has in some cases caused vomiting and other serious symptoms, from its containing as impurity sulphate of zinc. This, if present, would be easily discovered by the appropriate tests.

A more serious impurity has been lately detected by Mr. Bußsy, namely, the arseniate of potash. He found this poison in a sample of sulphate, supplied by a wholesale house in Paris. ("Pharm. Journ." May, 1872, p. 954.) This impurity may be derived from arsenical sulphuric acid used in its manufacture. It would be proper to test for arsenic any sample of sulphate which has caused irritation. (See ARSENIC.) Arsenic may thus find its way into all medicines in which sulphate of potash is used, *e. g.*, the compound colocynth pill and the compound powder of ipecacuanha.

Sulphate of potash may be easily identified. It is in hard dry crystals, soluble in water, forming a neutral solution in which potash and sulphuric acid may be discovered by the appropriate tests.

SALTS OF BARYTA.

Chloride of barium. Symptoms.—A woman, æt. 23, took by mistake for Epsom salts less than a teaspoonful (100 grains) of the chloride. This was at 12.30, 1st October, 1858. In half an hour there was a feeling of deadly sickness, with sharp burning pains in the stomach and bowels. Vomiting and purging set in violently, the purging being attended with straining. An hour and a half after she had taken the poison, the following symptoms were observed by Mr. Walsh: Face pale and anxious, eyes deeply sunk, surface cold, heart's action feeble, pulse scarcely perceptible, tongue natural and warm, loss of muscular power, sensation and intelligence not affected, pupils natural. Fluids taken were instantly rejected with a ropy mucus. There was pain in the stomach, singing in the ears, twitching of the face, and twisting of the legs and arms. At 9 P. M. the symptoms had abated, but at 2 A. M. (*i. e.* in about fourteen hours) the purging had returned, and the symptoms were much worse. There was a loss of voluntary muscular power. The breathing was slow and labored, and indicated effusion in the bronchial tubes, but the woman was sensible. Soon after 3 A. M. she was convulsed, and these convulsions continued in paroxysms for two hours,

when she died, seventeen hours after taking the poison. During the she had several watery evacuations, and consciousness was lost. There was no post-mortem examination. ("Lancet," 1859, vol. 1, p. 211.)

Another fatal case from the chloride of barium is reported in "Pharmaceutical Journal" (Aug. 10, 1872, p. 117); but no account is given of the dose taken, or of the symptoms and appearances. M. Kennedy states that in using this compound as a medicine, he has found that few persons are able to bear the eighth of a grain; that it is analogous to corrosive sublimate, and that an overdose will produce similar effects. He has used it for many years, and he finds the proper dose from the twelfth to the sixteenth part of a grain; but he cites no instance of its acting as a poison in a dose of one or two grains. ("Lancet," July 5, 1873, p. 28.)

M. Chevallier met with a case in which *acetate of barium* had been supplied in a medicine in place of the sulphovinate of sodium. It caused the death of the patient, and produced serious symptoms in the druggist himself, who had swallowed a portion of the medicine, in order to show that there had been no mistake in its preparation. ("Ann. d'Hyg.," 1873, 1, p. 395.)

The *Carbonate of barium* has destroyed life on several occasions. A drachm of it has sufficed to prove fatal. A woman, æt. 28, took a mixture of carbonate and sugar in repeated doses, but in unknown quantities. She died on the second day, having suffered from vomiting, purging, pain, and other symptoms of irritation. On inspection, the mucous membrane of the stomach and intestines was inflamed. The carbonate was found in the stomach. ("Brit. Med. Journ.," Dec. 1877, p. 888.) In another case which occurred to Dr. Wilson, a young woman swallowed half a teaspoonful of the powdered carbonate, mixed with water, at a time when she had been fasting twenty-four hours. There was no particular taste. In two hours, she experienced dimness of sight, double vision, singing in the ears, pain in the head, and throbbing in the temples, with a sensation of distension and weight at the pit of the stomach. There was also palpitation of the heart. After a time she complained of pain in the legs and knees, and cramps in the calves. She vomited twice, a fluid like chalk and water. The skin was hot and dry, the pulse frequent, full, and hard. These symptoms gradually abated, and she recovered, although the pain in the head and stomach continued for a long time. ("Med. Gaz.," 14, p. 448.) The carbonate is used as a poison for rats and mice.

Analysis.—*Chloride of barium* crystallizes in plates: it is soluble in water. 1. The solution yields an insoluble white precipitate of alkaline sulphate with sulphuric acid. This precipitate is nearly soluble in nitric acid. 2. The powdered salt, burnt on platinum wire in a smokeless flame, imparts to it a greenish yellow color. 3. Chlorine may be detected in it by a solution of nitrate of silver.

Carbonate of barium is a white insoluble powder. It is entirely dissolved with effervescence (carbonic acid) by diluted hydrochloric acid. On evaporation, it yields crystalline plates of the chloride, which may be tested by the processes above mentioned.

CHAPTER X.

PHOSPHORUS.—SYMPTOMS AND APPEARANCES.—CHRONIC POISONING.—
CHEMICAL ANALYSIS.—RED OR ALLOTROPIC PHOSPHORUS.

PHOSPHORUS is not often used in attempts at murder. The smell and taste as well as its luminosity commonly reveal its presence. At the Norwich Autumn Assizes, 1871 (*Reg. v. Fisher*), a girl of eighteen was convicted of an attempt to poison a family. She put a vermin compound containing phosphorus into a teapot containing tea. When hot water was poured on it, the smell at once led to suspicion. Phosphorus was found in the tea, taken from a pot carelessly left about the house. The girl was convicted, and sentenced to penal servitude for life. The late Professor Casper, of Berlin, describes a case in which the luminous appearance of the poisoned food led to a suspicion of poisoning with phosphorus, and this was subsequently proved. A woman put a preparation of phosphorus into some soup, and gave it to her husband. He ate it in a dark room in the presence of some friends, and they noticed that the liquid as he stirred it was luminous. (*Vierteljahrsschrift*, July, 1864.) In this way a person may be warned and a life saved. (See "*Ann. d'Hyg.*," 1870, 2, 203.)

Symptoms.—Phosphorus acts as an irritant poison, but its operation is attended with some uncertainty, according to the state in which it is taken. The symptoms are frequently slow in appearing: it is only after some hours, and sometimes even one or two days, that signs of irritation with convulsions and spasms appear; but when these once come on, the case proceeds rapidly to a fatal termination. In the first instance the patient experiences a disagreeable taste resembling that of garlic, which is peculiar to this poison. An alliaceous or garlic odor may be perceived in the breath. There is an acrid burning sensation in the throat, with intense thirst, nausea, severe pain and heat, with tenderness and a pricking sensation in the stomach, followed by distension of the abdomen and frequent vomiting. The vomited matters are black, or of a dark green or coffee-ground color, and have the odor of garlic; white vapors may be seen to proceed from them, and in the dark they may even appear phosphorescent. Purging has been noticed among the symptoms, and the motions have been observed to be luminous in the dark. The pulse is small, frequent, and scarcely perceptible. There is great prostration of strength and coldness of the skin, with other symptoms of collapse. The patient may die quietly in a comatose state, or be convulsed before death. Jaundice has been observed among the symptoms.

A woman, æt. 26, swallowed a decoction of lucifer-matches in coffee. In an hour an emetic was given to her, and she vomited half a pint of clear glairy fluid, having the smell of phosphorus, and containing par-

ticles of blue coloring matter (Prussian blue) derived from the matches. She had no pain in the stomach, and no purging. In four days she appeared to have recovered; but about this time there was bleeding from the nose; she was jaundiced, and blood appeared in the matter vomited. Febrile symptoms set in with purpura, and she died in about a week after taking the poison. ("Ed. Monthly Journal," Oct. 1860.) On April 20, 1861, a girl swallowed a quantity of phosphorus-paste. When seen soon afterwards by Mr. Parsons, of Bridgewater, her lips as well as parts of her dress were smeared with this substance, and there was a strong odor of phosphorus in her breath. Her countenance was tranquil: her pulse regular: there was no sickness or nausea, and she complained of nothing but slight thirst. Her symptoms were so slight that they excited no suspicion that the girl had swallowed the poison. She passed a restless night, and the next day she complained of heat in the mouth and throat, and of a slight sensation of nausea and retching. There was no pain or tenderness in the region of the stomach, the pulse was regular but weak. On the 22d she dressed herself and was able to walk about the ward: she left the hospital and went home, having walked a mile: she had her tea as usual at night, and went to bed. On the following day, the 23d, she complained of pain in her bowels, with sickness and purging. These symptoms became worse. On the 25th there was pain in the bowels, which were tender on pressure and slightly tympanic. The pulse was intermittent, and the girl was fast sinking. She died on the 26th, having survived the effects of the poison nearly a week, and no well-marked symptoms having set in until *the fifth day*. An inspection of the body was not permitted, and the only fact observed after death was a tendency to rapid putrefaction. The whole of the body became speedily livid, and the finger-nails were blue—a condition noticed by a witness to have existed before death. (For other cases, see "Ann. d'Hyg.," 1869, 2, 397.)

It will be perceived that, in reference to the delay in the appearance of symptoms, their slightness taken as a whole, and the time at which death occurred, this case is similar to the one previously related. If it were not for the peculiar character of the circumstantial evidence, these cases might easily throw a practitioner off his guard in forming an opinion.

Chronic poisoning.—Chronic poisoning by phosphorus is accompanied by nauseous eructation, frequent vomiting, a sense of heat in the stomach, purging, straining, pains in the joints, wasting, hectic fever, and disease of the stomach, under which the patient slowly sinks. Some interest is attached to the chronic form of poisoning by phosphorus from the researches of Dr. Strohl and others, on the effects of the *vapor* upon persons engaged in the manufacture of phosphorus or lucifer matches. It has been remarked that such persons have suffered from necrosis of the jaw, carious teeth, and abscesses. There has been also great irritation of the respiratory organs, and bronchitis has frequently shown itself among them. (See "On Poisons," 2d edit. p. 345.)

Appearances.—Among the appearances produced by phosphorus are marks of irritation and inflammation in the stomach and intestines. The stomach has been found much contracted, and its mucous membrane

inflamed, occasionally softened and presenting purple or violet-colored spots. Mr. Worbe found the stomach perforated in three places in a dog which had been poisoned by a solution of phosphorus in oil. In one fatal case the body was found in a state of great muscular rigidity. The membranes of the brain were congested, and there was serous effusion between them. The substance of the brain was also congested. The heart was flaccid and nearly empty. The mucous membrane of the stomach, gullet, and small intestines was very red, and there were patches in which the membrane was destroyed. When the stomach was opened, a white vapor escaped, accompanied by a strong smell of phosphorus. This organ contained a tablespoonful of a viscid greenish matter, from which particles of phosphorus with some Prussian blue (used as a coloring for the phosphorus-paste), subsiding on standing. ("Lancet," June 13, 1857, p. 600.) The mucous membrane has been found raised in small bladders or vesications, but this appearance was probably owing to putrefaction, as the body was not examined until twenty-three days after death. Schuchardt describes the blood as dark and fluid, and it does not become red on exposure to the air. Ecchymoses are sometimes found on the skin and on the surfaces of various organs. ("Brit. and For. Med. Rev.," 1857, vol. 19, p. 506. "Journal de Chimie Médicale," 1857, p. 84.) Among the appearances met with in the acute form of poisoning is a fatty degeneration of the voluntary muscles as well as of the liver, heart, and kidneys. (See a paper on this subject by Dr. Moore, "Dublin Medical Press," Nov. 15, 1865.)

In one case which I examined in 1867, that of a girl, æt. 13, who died on the sixth day after taking phosphorus-paste beaten up with egg, there were the usual symptoms, with severe paroxysms of vomiting and pain. The matters first vomited were observed to be luminous in the dark. There were numerous ecchymosed patches in the cellular tissue of the skin of the abdomen over the rectus muscle; these were also seen on the chest and on the diaphragm. The stomach contained a dark-colored thick fluid like altered blood; the coats were not inflamed; the surface of the inner coat was covered with a brownish-colored mucus which had no odor of phosphorus. At the greater curvature the surface was dotted over with numerous small dark particles, consisting of coagula of altered blood adhering to the membrane, but easily removed from it. They had the appearance of effused coagula of blood in petechial spots. The contents of the stomach owed its color to these little masses of blood being diffused through them. The duodenum contained a similar liquid. The intestines presented no abnormal appearance. The liver was in an advanced state of fatty degeneration. This condition of the liver has occurred so frequently in cases of phosphorus-poisoning, that it is now regarded as one of the characteristic appearances. ("Guy's Hospital Reports," 1868, p. 242.) M. Tardieu has met with fatty degeneration in poisoning with phosphorus, not only in the liver, but in the heart and kidneys. ("Étude Méd.-Lég. sur l'Empoisonnement," 1867, p. 441.) In his work the reader will find a complete history of this form of poisoning.

In a case recorded by Dr. Habershon ("Med. Chir. Trans.," 1867, vol. 50), in which a woman died on the fifth day, the symptoms and appearances were similar to those above described. The phosphorus

was taken in the form of paste, and it is supposed in a dose of from three to four grains. There was much ecchymosis in patches, in and about the cellular tissue of the abdomen and chest. There was fatty degeneration of the liver and kidneys. The stomach contained a large quantity of fluid like soot and water, and was covered with a tenacious bloody mucus. There was some congestion in the mucous membrane, and there was much redness with ecchymosis in the small intestines.

The viscera, and even the flesh of animals recently poisoned by phosphorus, have the peculiar odor of this substance, and they are frequently luminous in the dark. (Galtier, "Toxicologie," vol. 1, p. 184.) Mr. Clowes informed me, that in examining some fowls which had been poisoned with phosphorus, he was struck with the strong odor of this substance on opening the gizzards, and with the appearance of a fine white fume, which was luminous when observed in a dark room. In the case of a woman who died while taking phosphorus medicinally, it was remarked that the whole of the viscera were luminous—thus indicating the universal diffusion of this poison by absorption. (Casper's "Wochen-schrift," 21 and 28 Feb. 1846, 115, 135.)

Fatal dose.—That phosphorus is a powerful poison, is proved by two cases quoted by Sir R. Christison. In one, death was caused by a grain and a half in twelve days; in the other, by two grains in about eight days. It has been supposed to operate as a poison only by becoming converted into phosphorous acid; but although this conversion takes place, it is probable that phosphorus passes directly into the blood, since the urine voided during life has been observed to be luminous: hence it is itself probably a blood-poison.

Period at which death takes place.—This has varied greatly, in the cases hitherto observed, from a few hours to a week. In a case related by Orfila, death took place in four hours. In another also related by him, death occurred only after seventeen days. Dr. Habershon quotes a case which is said to have proved fatal in half an hour. ("Med. Chir. Trans.," 1867, vol. 50.) This is the shortest period recorded. In general, several days elapse before a fatal result occurs, and during this time the patient undergoes much suffering. This was observed in a young woman who swallowed a quantity of phosphorus-paste intended for poisoning rats. She did not die until the fifth day. ("Journal de Chimie Méd.," 1845, p. 508.) In two cases of acute poisoning with phosphorus communicated to me by the late Dr. W. D. Moore, one proved fatal in seventy-two, and the other in eighty-eight hours. The symptoms and appearances were similar to those already described. Fatty degeneration of the liver and other organs was especially marked. ("The Medical Press," Nov. 15, 1865, p. 434.) In a case which occurred to Dr. Anderson, a child aged one year and eight months had sucked the heads off about twenty phosphorus-matches before it was detected. No symptoms appeared until the second day, when the child was drowsy and slept for twenty hours. Castor oil and oil of turpentine were given. On the fourth day, it vomited; the skin was hot, tongue dry, there was great thirst with a quick pulse and cold extremities. On the sixth day, there was much vomiting of a matter like coffee-grounds (altered blood). There was great pain in the stomach; the child became unconscious, and

gradually sunk, dying on the seventh day after taking the poison. There was no purging, but the motions were passed involuntarily, containing coagulated blood. An alliaceous odor was perceived in the breath during the progress of the case, and the body had a yellowish (icteric) tint. There was no odor of phosphorus noticed on post-mortem inspection, nor were the viscera luminous in the dark. Phosphorus could not be detected by Mitscherlich's process. ("Lancet," 1871-2, 189.) In February, 1880, a death took place in London from an overdose of the *oleum phosphoratum*, which had been given by mistake for phosphorized cod-liver oil. Two teaspoonfuls were taken, but the exact strength of the preparation is not stated. The woman died suddenly, and the poison in this case caused perforation of the stomach.

Chemical analysis.—Phosphorus is a solid, of waxy consistency, having a peculiar odor and taste resembling garlic. It is the odor and taste which prevent it from being criminally employed as a poison, and render it easy of detection in articles of food. It evolves a white vapor in daylight and a faint bluish luminosity in the dark. It melts and takes fire at a temperature of 113° , burning with a bright yellow flame, and producing thick white acid vapors by combustion. It is not soluble in water, although water in which it has been kept acquires poisonous properties by reason of the phosphorous acid formed. It is dissolved by alcohol, ether, chloroform and the oils. Its most perfect solvent is the sulphide of carbon.

Organic mixtures.—The smell which phosphorus imparts to solids and liquids is remarkably characteristic. When it has been taken in a solid form, the particles may be separated as a sediment, by washing the contents of the stomach in water. These may be melted under water into one mass, either by plunging the tube containing them into hot water, or by pouring hot water upon them in a glass. If a portion of the organic liquid is exposed in the dark, the particles of phosphorus will be easily recognized by their luminosity, as well as by their combustion, when the surface on which the material is spread is heated. Owing to its great solubility in sulphide of carbon, phosphorus may be separated from many organic matters by digestion with this liquid. It is thus procured from flour and phosphorus-paste, or from the residue of the contents of the stomach after washing and decantation. On the spontaneous evaporation of the sulphide, decanted from the organic liquid or solid, the phosphorus may be procured in small globules or beads. These are ignited when touched with a hot wire, and burn with the bright flame of phosphorus.

If the phosphorus is in a state of solution, or is in too small quantity to be dissolved out of the material by sulphide of carbon, its presence may be indicated by distilling the liquid containing it in the dark—the boiling point being raised by the addition of sulphuric acid. The vapor appears luminous as it is condensed in the glass condensing-tube. So delicate is the process of distillation, which was first suggested by Mitscherlich, that in one experiment with the head of a single lucifer-match the luminosity appeared for half an hour in the condensing-tube. The most absolute darkness is required for the success of this experiment.

[It should be remembered that the presence of the vapor of alcohol, chloroform, etc. (substances in which the viscera of the body may have been preserved), may entirely prevent the luminosity in the above experiment.—R.]

If the person has survived several days, it is not likely that any free phosphorus will be found in the stomach or contents. None was found in the stomach contents or fatty liver of the girl on the sixth day (page 131), but the distillation process succeeded with the broken top of the pot which had held the phosphorus-paste, although this was empty and had been thrown into a tub of water. In Dr. Habershon's case of death on the fifth day, none was found by Dr. Stevenson in the stomach or contents. The phosphorus in these cases is oxidized rapidly, and thus, like other poisons, it may disappear from the body. Under these circumstances, it may, according to some authorities, be still discovered as phosphoric acid, combined with some base probably ammonia: but as the phosphates are found in the secretions, which are generally acid, it would be difficult to satisfy the court that their presence proved poisoning by phosphorus, unless the symptoms, appearances, and circumstantial evidence were so strong that chemical evidence was scarcely necessary.

The remarkable substance, known under the name of *allotropic phosphorus*, is not possessed of poisonous properties. This fact, long since announced by Liebig ("Letters on Chemistry," 1855), has been since confirmed by experiment. It has been given to animals in doses of thirty grains, without causing symptoms of poisoning. In October, 1860, a woman, æt. 26, swallowed the composition scraped from a number of Lucifer matches made with allotropic phosphorus. She suffered no inconvenience. She procured other matches of common phosphorus, took a decoction of them in coffee, and died from the effects.

Analysis.—Allotropic phosphorus is easily recognized by its red color and infusibility. When a mixture containing it is heated to about 500° , it burns like common phosphorus, and yields similar products. It is insoluble in all liquids, and by its insolubility in sulphide of carbon it is distinguished and separated from common phosphorus. It has no odor or taste, and is not luminous in the dark.

IODINE.

Symptoms.—From experiments on animals, as well as from observation of its effects on man, iodine has a strong local action as an irritant on the stomach and bowels. In large doses, it occasions a burning heat in the throat, severe pain in the abdomen, with vomiting and purging; the vomited matters having the peculiar odor of iodine, and being of a yellow color, except when any farinaceous food has been taken, in which case they are blue, or even black. The fecal matters may also contain iodine, if the poison has been taken in the solid state. Besides these symptoms, there is great thirst, with anxiety, headache, giddiness, trembling and convulsive movements of the limbs, and fainting,—these last symptoms indicating that the poison has become absorbed. When taken for some time in small doses, it gives rise to salivation, vomiting

and purging, pain in the stomach, and cramps; the pulse becomes small and frequent; there is a general wasting of the body; and it has been observed that, in this form of chronic poisoning, certain glands are liable to become affected and diminished by absorption—the breasts in the female, and the testicles in the male. Iodine produces these secondary effects (iodism), whether it is taken internally or applied externally.

Iodine is rarely used as a poison. In May, 1864, an attempt was made by a woman to poison a fellow-servant by mixing tincture of iodine with food in a plate. The remarkable discoloration of the farinaceous food which it produced led to suspicion, and prevented any ill effects from following. Iodine gives a blue, green, or dark color to most organic liquids, and imparts to them a peculiar odor. It stains the skin and other organic substances yellow, the color being removed by an alkali. When in strong solution it is corrosive, and destroys the parts which it touches; in this state it has been maliciously employed for throwing on the person.

Appearances after death.—As this is an irritant as well as a corrosive poison, the lining membrane of the gullet, stomach, and intestines is found inflamed and excoriated. In one instance the mucous membrane near the pylorus was corroded, and detached in a space of two or three inches.

Analysis.—The odor is sufficient to identify it. This may be concealed by alkalies or alkaline substances. When heated, it sublimes in a purple vapor. The addition of a cold solution of starch produces a blue color, but many substances prevent this reaction. It is very soluble in sulphide of carbon, forming a rich pink solution. The sulphide has the property of removing it from water and other liquids in which it is dissolved. It may thus be separated for chemical examination, by decanting the watery liquid from the sulphide, which, on evaporation, leaves the iodine in crystals.

METALLIC IRRITANTS.

CHAPTER XI.

ARSENIC.—ARSENIOUS ACID.—SYMPTOMS.—CHRONIC POISONING.—APPEARANCES AFTER DEATH.—FATAL DOSE.—CHEMICAL ANALYSIS.—ARSENITES.—ARSENIC ACID.—ORPIMENT AND OTHER COMPOUNDS.

White arsenic. Arsenious acid.—It occurs under the form of a white powder, visibly crystalline in a strong light, or when viewed with a lens. It is also met with, but more rarely, in opaque brittle masses resembling enamel. It possesses a feeble acid reaction when dissolved in water. It is often incorrectly described as having an *acrid taste*; a small quantity of it has certainly no appreciable taste. It would appear from numerous cases on record, that it has been unconsciously taken in fatal quantities in all descriptions of food, without exciting the least sensation on the tongue. Water boiled for an hour on the poison and allowed to cool, holds dissolved the 40th part of its weight, or about twelve grains in one ounce. If boiled for a shorter time, not more than the 80th part will be dissolved. Cold water allowed to stand for many hours on the poison does not dissolve more than from the 1000th to the 500th part of its weight; *i. e.*, one half grain of arsenic to nearly one fluidounce of water. When arsenic in powder is mixed with cold liquids, a portion of the powder floats and adheres to the sides of the vessel. This appearance has sometimes led to a suspicion of poisoning.

Symptoms.—These vary according to the form and dose in which it has been administered. The time at which they usually come on is generally in from half an hour to an hour after the poison has been swallowed. They may appear earlier or much later. In a case in which one drachm of white arsenic had been taken on an empty stomach, no symptoms appeared for two hours; in another that occurred to Dr. Laclède, in which a large dose was taken, there were no symptoms for seven hours. (“*Ann. d’Hyg.*,” 1837, vol. 1, p. 344. See also “*Med.-Chir. Rev.*,” Jan. 1854, p. 294.) And in a third their appearance was protracted for *ten* hours, the maximum period yet known. [A case is mentioned by Dr. Wood (“*U. S. Dispensatory*,” 1865, p. 26), where a drachm had been swallowed, and the symptoms of poisoning were delayed for *sixteen* hours.—R.] In all cases in which arsenic enters the system from without, as by its application to the skin, or to ulcerated or diseased surfaces, the symptoms are rarely manifested until after the lapse of some hours or even days.

The person first experiences a feeling of sinking or faintness, depression, nausea, followed by sickness, with an intense burning pain in the region of the stomach, increased by pressure. The pain in the abdomen becomes more and more severe, and there is violent vomiting of a brown turbid matter, mixed with mucus, and sometimes streaked with blood. These symptoms are followed by purging, which is more or less violent, and this is accompanied by severe cramps in the calves of the legs. The matters discharged from the stomach and bowels have had in some instances a yellowish color, as it was supposed, from a partial conversion of the poison of sulphuret, but more probably from an admixture of bile. The vomited matters are in some cases colored with blood, and the mixture of blood with bile has often given to them a green or brown color. In other cases, they may consist of a large quantity of mucus ejected in a flaky state and having a milky-white appearance, as if from admixture with the poison. The *color* of the vomited matters may be blue or black when colored arsenic has been taken, or the admixture of bile may render them of a deep green color. The vomiting is in general violent and incessant, and is excited by any liquid or solid taken into the stomach. There is tenesmus (straining), and the discharges by the bowels are frequently tinged with blood. There is a sense of constriction, with a feeling of burning heat in the throat, commonly accompanied by the most intense thirst. The pulse is small, very frequent, and irregular; sometimes wholly imperceptible. The skin is cold and clammy in the stage of collapse; at other times it is very hot. The respiration is painful from the tender state of the stomach. There is great restlessness, but before death, stupor sometimes supervenes, with paralysis, tetanic convulsions, or spasms in the muscles of the extremities. In one instances trismus (lock-jaw) appeared in three-quarters of an hour. ("Orfila," vol. 1, p. 449.) Although pain is in general among the early and well-marked symptoms, arsenic appears in some cases to destroy sensibility. In a case in which the stomach was found intensely inflamed after death, the patient complained of no pain during the time she survived. Tamassia has found that the temperature of the body in animals under the influence of arsenic is much lowered.

[Cases of poisoning by arsenic present the greatest possible variety in the character, combination, and severity of the symptoms. Most frequently the symptoms are those just described. In a second class, they are those of collapse—there being extreme prostration of strength, a cold clammy skin, a frequent, almost imperceptible pulse, or one as low as thirty or forty beats in a minute. A third class is marked by the patient falling into a profound sleep, which terminates in a fatal coma.—R.]

Chronic poisoning.—Should the person recover from the first effects, and the case be protracted, or should the dose have been small and administered at intervals, there will be inflammation of the conjunctivæ, with suffusion of the eyes and intolerance of light conditions which are, however, often present among the early symptoms above described. ("Med. Times," Aug. 30, 1851, p. 229.) There is also irritation of the skin accompanied by a vesicular eruption, which has been called *eczema arsenicale*. Sometimes this has assumed the form of nettle-rash, or of the

eruption attending scarlet fever. Local paralysis, preceded by numbness or tingling in the fingers and toes, and other symptoms of nervous disorder, are also common consequences. Exfoliation of the cuticle and skin of the tongue, with the falling off of the hair, has likewise been witnessed. (Case of the *Turners*, 1815, Marshall, 119.) Salivation has been observed to follow, especially when small doses of the poison have been given for a length of time. ("Med. Gaz." vol. 16, p. 790.) Strangury and jaundice have been noticed among the secondary symptoms. ("Marshall on Arsenic," 44, 111.)

Arsenic is not an accumulative poison; it is temporarily deposited in the organs after absorption, but is rapidly eliminated by the urine; and in from two to three weeks, if the person survives, the whole of that which has been absorbed may be removed from the body. Dr. C. Maclagan states that it begins to pass out of the body by the urine as early as three-quarters of an hour after it has been taken. ("Ed. Med. Jour.," Sept. 1861, p. 260.)

Appearances after death.—The principal changes produced by arsenic are generally confined to the stomach and bowels. They are commonly well marked in proportion to the largeness of the dose, and the length of time which the person has survived after taking the poison. Our attention must be first directed to the *stomach*. Arsenic seems to have a specific effect on this organ; for, by whatever channel the poison may have entered into the system, whether through a wounded, diseased, or ulcerated surface, or by the act of swallowing, the stomach has been found inflamed. The mucous membrane of the stomach is sometimes partly detached and is covered with a layer of mucus, mixed with blood or bile, and with a thick white pasty-looking substance containing arsenic. It is commonly found red and inflamed in dotted or striated patches, extending between the two apertures; the color, which is of a dull or brownish-red, becomes brighter on exposure to the air: at other times it is of a deep crimson hue, interspersed with black-looking lines, or patches of altered blood. The redness is usually most strongly marked at the greater end; in one case it may be found spread over the whole mucous surface, giving to it the appearance of red velvet; in another it will be chiefly seen on the prominences or folds of the membrane. In one instance the coats were thickened and of a gelatinous consistency, without any marked inflammatory redness.

The stomach has been found highly inflamed in a case which proved fatal in *two hours*. Thus it would appear that intense inflammation of the mucous membrane may be observed within a very short period. This organ usually contains a mucous liquid of a dark color tinged with blood. The coats are sometimes thickened in patches, being raised up into a sort of tumor, with arsenic imbedded in them; at other times they have been found thinned. The mucous membrane is rarely found ulcerated, and still more rarely gangrenous. Ulceration of the membrane, as the result of the action of arsenic, has been found as early as ten hours after the poison had been taken. Perforation of the coats is not a common result of arsenical poisoning; there are but few instances on record. Various appearances are said to have been met with in the lungs, heart, brain and urinary organs; but they are not so characteristic of arsenical poi-

soning as to admit of medico-legal use in enabling a medical man to distinguish poisoning from disease. It is to the stomach and intestines that he must look as the basis of reliable evidence in regard to appearances after death. Dr. Wilks met with an ecchymosed condition of the lining membrane of the left ventricle of the heart in a case in which a man died in twelve hours, from acute poisoning by arsenic. In a few instances, the mouth, throat and gullet have been found inflamed, but in general there are no changes in these parts to attract particular attention.

The mucous membrane of the *small intestines* may be inflamed throughout, but commonly the inflammatory redness is confined to the upper part, *i. e.*, the duodenum, especially to that portion of it which joins the stomach. Of the large intestines, the rectum appears to be the most prone to inflammation. The liver, spleen, and kidneys present no appearances which can be connected with the action of arsenic, although these, like the other soft organs, may become receptacles of the absorbed poison. It is worthy of observation in relation to the known antiseptic properties of arsenic, that the parts especially affected by this substance (the stomach and intestines) occasionally retain the well-marked character of irritant poisoning for a long time after death. Absorbed arsenic does not, however, appear to prevent the decomposition of the soft organs in which it is deposited.

Action of Arsenic through the Skin.—Arsenic may destroy life as the result of external application to the skin, to any diseased or ulcerated surface, or to a wound. (See "Guy's Hospital Reports," Oct. 1864, p. 220.) Some importance is attached to this form of arsenical poisoning from the fact that the lives of many infants have been recently (June, 1878), destroyed by the use of a powder sold under the name of *rislet powder*. Instead of employing pure starch in the manufacture of this powder, some makers, in order to increase their profits, have recommended as a substitute terra alba, or powdered gypsum (sulphate of lime). As in the Bradford lozenge case ("Poisons," 3d ed., p. 354), arsenic has been ignorantly substituted for sulphate of lime, and has caused the deaths of many infants by external application. In twenty-eight cases in which this powder had been used to infants, there were twelve or thirteen deaths. ("Brit. Med. Journ.," June 1, 1878, p. 795.) It set up inflammation and irritation in the skin, and was then absorbed. In a case which occurred to Dr. Tidy, the child was born on the 29th May. It was washed and then dusted over with this poisoned powder; this was also applied to its genital organs. On the second day after birth the powder was applied four times. There was at this time an unnatural redness of the skin. On the third day the skin was intensely red, and appeared unhealthy about the navel and vagina. The powder was then withdrawn, but the eruption became worse, and in some parts the skin had a sloughy appearance. On June 7th, the tenth day of the child's life, and on the sixth day from the last application of the powder, the child died from the effects of the absorbed poison. On a post-mortem examination there was nothing remarkable in the condition of the viscera. The body was buried, but exhumed on the 28th June for examination. Dr. Tidy found in the liver 1.5 grains of arsenic, in the stomach and

intestines one grain, and in the kidneys, traces. The powder used, which should have consisted of starch and magnesia, with orris-root, contained 38.5 per cent. of arsenic, with starch and magnesia. ("Lancet," Aug. 24, 1878, p. 250.) For one of the deaths thus caused, the vendor of the powder was tried on a charge of manslaughter (*Reg. v. King*, C. C. C. 1878), but acquitted, and it was thus decided that there was no criminal neglect or culpable ignorance in a druggist not being able to distinguish arsenic from plaster of Paris. It was simply a case of *caveat emptor*. ("Pharm. Journ.," Aug. 1878, p. 119.)

Articles of dress may be sometimes the means of conveying the poison into the system. Arsenic is largely used in the manufacture of magenta and other coal-tar dyes, and it is not always removed by washing from the dyed article. MM. Bourquelot and Galippe examined a sample of red flannel which had caused an eruption on the skin of a weaver. Analysis showed that it contained a notable quantity of arsenic, sufficient to account for the eruption. ("Ann. d'Hygiène," March, 1880, p. 254.) Arsenic is very extensively diffused. It has been found in baking powder as a result of its having been used by mistake for carbonate of soda; also in commercial grape-sugar, in which case it is probably derived from the use of impure sulphuric acid. It is much used by confectioners, brewers, and others. It has been found in soot as a product of the combustion of the arsenical pyrites contained in coal. It is largely contained in green and other colored papers.

The smallest *fatal dose* of arsenic hitherto recorded is *two grains*. ("Provincial Med. Journal," June 28, 1848, p. 347; also, "Medical Gazette," vol. 39, p. 116.) Under circumstances favorable to the operation of this poison, the fatal dose in an adult may be assigned at from *two to three grains*. Large doses of arsenic commonly destroy life in from eighteen hours to three days. The average time at which death takes place is twenty-four hours; but the poison may destroy life in a much shorter period. In a case which occurred in April, 1849, death took place in two and a half hours. ("Guy's Hospital Reports," Oct. 1850, 183. See, also, "Ann. d'Hyg." 1837, vol. 1, p. 339.) Mr. Foster, of Huntingdon, met with the case of a child under three years of age, who died within *two hours* from the effects of arsenic. One (a doubtful) case is said to have proved fatal in twenty minutes. On the other hand life is occasionally protracted for many days. In October, 1847, a man who had swallowed 220 grains of arsenic was admitted into Guy's Hospital, and died on the *seventh* day. In the case of *Dr. Alexander*, death took place on the *sixteenth* day; and although a large quantity of arsenic had been taken, no traces were found in the body. ("Med. Times and Gazette," April 18, 1857, p. 389.) In an instance in which arsenic was applied externally to the head, the person did not die until the *twentieth* day.

The longest duration of a case of poisoning by arsenic is probably that reported by Belloc. A woman, æt. 56, employed a solution of arsenic in water to cure the itch, which had resisted the usual remedies. The skin became covered with an erysipelatous eruption, and the itch was cured, but she experienced severe suffering. Her health gradually failed, and she died after the lapse of *two years*, having suffered during

the whole of this period from a general tremor of the limbs. ("Cours. de Méd. Lég.," 121.)

In cases of arsenical poisoning, it is frequently difficult to trace the source of the poison. Wrought or sheet iron is sometimes enamelled with a white composition containing arsenic, and the vessels thus glazed have been used for culinary purposes. Such a practice is highly dangerous, as the poison may thus find its way into food.

Chemical analysis. Arsenic as a solid.—In the simple state, *white arsenic* may be identified by the following properties: 1. A small quantity of the powder, placed on platinum foil, is entirely volatilized at a moderate heat (370°) in a white vapor. If a small portion of the white powder is very slowly heated in a glass tube of narrow bore, it will be sublimed without melting, and form a ring of minute octahedral crystals, remarkable for their lustre and brilliancy. Under a microscope of good magnifying power (250 diameters), the appearance of these crys-

Fig. 5.
Crystals of arsenious acid by sublimation, magnified 30 diameters.

tals is highly characteristic (Fig. 5). 2. On boiling a small quantity of the powder in distilled water, it is not readily dissolved, but it partly floats as a white film, while another part becomes aggregated in small lumps at the bottom of the liquid. It requires long boiling in order that it should become perfectly dissolved and equally diffused through water.

3. When a small portion of the white powder, *i. e.*, from one-fourth to one-twentieth part of a grain, is heated with two parts of *soda flux* (obtained by incinerating acetate or tartrate of soda in a close vessel) [or with an excess of perfectly dried *ferrocyanide of potassium*.—R.] in a glass tube about three inches long, and from one-eighth to a quarter of an inch in diameter, it is decomposed; a ring of metallic arsenic of an iron-gray color is sublimed and deposited in a cool part of the tube. During the reduction there is a perceptible odor, resembling that of garlic, which is possessed by metallic arsenic only, while passing from a state of vapor to arsenious acid. In this experiment of *reduction*, there are frequently two rings deposited in the tube (Fig. 6); the upper and

Fig. 6.

Ordinary reduction tube, with two sublimate; the upper, brownish-black; the lower, the pure metal in an annular deposit.

larger ring has a brown color, and appears to be a mixture of finely divided metallic arsenic and arsenious acid; the lower ring is small and consists of the pure metal. The appearance presented by these sublimate is indicated in the annexed illustration. By heating gently the tube containing the sublimate (reduced to powder) in another tube of larger diameter, the metallic arsenic during volatilization, forms octahedral crystals of arsenious acid, which, after examination by the microscope, may be dissolved in a few drops of water, and tested by one or more of the liquid reagents.

The metallic sublimate, or the crystals produced from them, may be further subjected to the following process: Break the glass on which the sublimate is deposited into fragments, and digest these in a few drops of the strongest nitric acid containing nitrous acid, previously proved to be free from arsenic. The sublimate is thereby converted into arsenic acid. The acid solution should be evaporated to dryness; the white uncrystalline residue obtained should be dissolved in a few drops of distilled water, and a strong solution of nitrate, or of ammonio-nitrate, of silver added in small quantity to the residue. A brick-red coloration indicates arsenic acid, and thus proves incontestably that the sublimate was of an arsenical nature. Ozonic ether also oxidizes the metallic deposit and slowly converts it into arsenic acid which is left in a pure state on evaporation. The upper or brownish looking sublimate may be readily converted into one of the pure metal, by gently heating it in the flame of a spirit lamp. Arsenious acid is then volatilized, and an iron-gray deposit of metallic arsenic appears. If the heat is continued, the whole of the metallic sublimate is volatilized and deposited in a cool part of the tube, in transparent and colorless octahedra of arsenious acid. This is the special character of an arsenical sublimate: it may be thus distinguished from sublimate of all metals, or metalloids. The lower metallic sublimate procured by reduction sometimes presents itself, not in an annual form, but in detached particles of a somewhat globular shape. These are of an iron-gray color, quite unlike sublimed mercury and when examined by the microscope, it may be seen that they consist of crystalline masses nucleated, and that they are not strictly spherical. This sublimate is frequently produced in the last stage, when the residue in the tube is strongly heated. *The process of reduction*, with the corroborative results above mentioned, is, when thus applied, conclusive of the arsenical nature of the substance under examination.

Bettendorff has suggested a method for the reduction of arsenic in the wet way. A saturated solution of chloride of tin is mixed with its volume of fuming hydrochloric acid and brought to the boiling point. If the hydrochloric acid is pure, it should remain colorless, but if it contains a trace of arsenic, the liquid will acquire a light brown color. On adding a minute quantity of solid arsenious acid to such a mixture, it is dissolved and instantly decomposed, metallic arsenic being deposited in the form of a brown or brownish-black precipitate. A salt of antimony is not thus affected.

Arsenic in solution in water. Liquid tests.—The solution of arsenious acid is clear, colorless, possesses scarcely any perceptible taste, and

has but a feebly acid reaction. In this state, we should first evaporate slowly a few drops on a glass slide, when a crystalline deposit will be obtained. On examining this with a microscope, it will be found to consist of numerous minute octahedral crystals, presenting triangular surfaces by reflected light. (See Fig. 7.)

1. *Silver test*.—On adding to the solution of white arsenic *ammonio-nitrate of silver*, a pale yellow precipitate of arsenite of silver falls down; changing, under exposure to daylight, to an olive-green color. The test is made by adding to a strong solution of nitrate of silver, a weak solution of ammonia, and continuing to add the latter, until the brown oxide of silver, at first thrown down, is almost redissolved. The yellow precipitate is soluble in nitric, tartaric, citric, and acetic acids, as well as in ammonia. It is not dissolved by potash or soda.

2. *Copper test*.—On adding to another portion of the solution *ammonio-sulphate of copper*, a light-green precipitate (arsenite of copper) is formed, the tint of which varies according to the proportion of arsenic present, and the quantity of the test added; hence, if the arsenic is in small proportion, no green precipitate at first appears; the liquid simply acquires a blue color from the test. In less than an hour, if arsenic is present, a bright green deposit is formed, which may be easily separated from the blue liquid by decantation. This test is made by adding ammonia to a weak solution of sulphate of copper, until the bluish-white precipitate, at first produced, is nearly redissolved; it should not be used in large quantity if concentrated, as the deep blue color tends to obscure or conceal the green precipitate formed. The *dried* precipitate of arsenite of copper, when slowly and moderately heated in a well-dried reduction-tube, will yield a ring of octahedral crystals of arsenious acid—oxide of copper being left as a residue.

3. *Sulphuretted hydrogen test*.—The gas may be procured by adding to sulphide of iron in a proper apparatus, a mixture of one part of strong sulphuric acid and three parts of water. The arsenical liquid should be slightly acidulated with pure diluted hydrochloric acid, *before* the gas is passed into it; at least, care should be taken that it is not alkaline. A yellow precipitate (orpiment) is immediately produced if arsenic is present, and it may be collected after boiling the liquid sufficiently to drive off any surplus gas. It is known to be sulphide of *arsenic* by the following properties: 1. It is insoluble in water, alcohol, and ether, as well as in diluted hydrochloric acid, and vegetable acids; but it is decomposed by strong nitric and nitro-hydrochloric acids. 2. It is immediately dissolved by potash, soda, or ammonia; forming, if no organic matter is present, a colorless solution. 3. When dried and heated with three parts of soda-flux, or an equal part of dry cyanide of potassium [or with dried ferrocyanide of potassium.—R.], it yields a sublimate of metallic arsenic.

Fig. 7.

Crystals of arsenious acid from a solution, magnified 124 diameters.

Marsh's process. Hydrogen test.—The action of this test depends on the decomposition of arsenious acid and its soluble compounds by nascent hydrogen evolved from the action of diluted sulphuric or hydrochloric acid on zinc. The materials should be first proved to be free from arsenic. The apparatus is of the most simple kind, and is so well known as to need no description or illustration. The arsenic may be introduced into the short leg of the tube in the state of powder; but it is far better to dissolve it in water, by boiling, either with or without the addition of a few drops of hydrochloric acid. The metallic arsenic combines with the hydrogen, forming arsenuretted hydrogen gas, which possesses the following properties: 1. Filtering paper wetted with a solution of nitrate of silver is immediately blackened by the gas—the silver being reduced to the metallic state. Lead-paper is not changed in color unless sulphuretted hydrogen is also present. 2. It burns with a pale bluish-white flame, and thick white smoke (arsenious acid). 3. A slip of glass or white porcelain held in the flame near the point (for not too long a time) acquires a dark stain from the deposit of metallic arsenic upon it. This deposit presents a metallic lustre in the centre

Fig. 8.

Deposit obtained by Marsh's Apparatus

A Metal. B Mixed deposit.
C Arsenious acid

of sulphide of arsenic. To a third, add a few drops of the strongest nitric containing some nitrous acid. The deposit is dissolved; evaporate the acid solution gently to dryness; carefully neutralize the residue, and add one or two drops of a strong solution of nitrate of silver. A brick-red stain, or a dark red precipitate of arsenate of silver will be produced.

Reinsch's process.—In the application of this process, the liquid suspected to contain arsenic, or the solid dissolved in distilled water, is boiled with from one-sixth to one-eighth part of pure hydrochloric acid (proved to be free from arsenic), and a small slip of copper is then introduced. A slip of polished copper foil (electric copper) about a quarter of an inch square, attached to the end of a thin platinum wire, may be employed for the experiment. The copper must be first proved to be free from arsenic, as this is a very common contamination of commercial copper in the form of foil, gauze, or wire. If arsenic is present in the liquid, even in small quantity, the polished copper acquires either immediately, or within a few minutes, a dark iron-gray coating from the deposit

of this metal. This is apt to scale off, if the arsenic is in large quantity, or if the liquid is very acid, or long boiled. We remove the slip of copper, wash it in water, dry it, and gently heat it in a small reduction-tube, when arsenious acid will be sublimated in minute octahedral crystals; if these should not be apparent from one piece of copper, several may be successively introduced. When the quantity of arsenic is small, the polished copper merely acquires a faint bluish tint. The deposit is in all cases materially affected by the quantity of water present, or, in other words, the degree of dilution; and sometimes it will appear only after the liquid has been much concentrated by evaporation. The presence of arsenic as an impurity in copper may be detected by the following method suggested by Mr. Abel: Add to pure hydrochloric acid, diluted with six parts of water, one or two drops of a weak solution of persulphate or perchloride of iron. Boil the acid liquid, and introduce the copper, well cleaned and polished, into the boiling liquid. Arsenicated copper soon acquires a dark tarnish, while the non-arsenicated (electric) copper retains its color under these circumstances.

Arsenic in liquids containing organic matter.—Arsenic may exist in an insoluble form—i. e., as a crystalline powder—in the contents of the stomach, or any liquid article of food. If coarsely powdered it may be separated as a heavy sediment, by careful washing with distilled water, and then dried and tested by the reduction process (p. 141). Any liquid for analysis should be strained through muslin, or filtered through paper in order to separate all insoluble matters: these should be well pressed and drained. Should the liquid be colored, this is of little moment, provided it is clear. If viscid, it should be diluted in water, and boiled with a small quantity of hydrochloric acid; on standing, a deposit may take place, and this should be separated by a filter. As a trial test, we may now boil in a portion of the liquid, acidulated with pure hydrochloric acid, a slip of pure copper highly polished, and examine any deposit on the metal by the method above described. If the copper comes out unchanged, there is no detectable quantity of arsenic present.

Let us assume that the organic liquid is milk or beer; it will be necessary to determine whether any arsenic is dissolved in it. Filter a portion; place it in a dialysing tube, and immerse the mouth of the tube in distilled water. In a few hours the arsenic will have traversed the animal membrane, and will be found in a clear and nearly colorless solution in water. The fluid tests may then be applied to this liquid for the detection of arsenic. They should never be applied directly to colored organic liquids. Viscid mucous and farinaceous liquids containing arsenic may be thus treated, and the arsenic speedily detected.

When arsenic is present in an organic liquid in large quantity, it may be precipitated as sulphide by a current of washed *sulphuretted hydrogen*. The liquid should be boiled, filtered, and acidulated with hydrochloric acid before passing the gas into it. When precipitation has ceased, the liquid should be again filtered, the precipitate collected, dried, and weighed. By operating on a measured portion of the solution, the amount of white arsenic present may be determined by the weight of the sulphide obtained: five parts by weight of sulphide being

equal to four parts of white arsenic. The properties of the yellow precipitate should be verified according to the rules mentioned at page 143.

Distillation process.—When the poison is in so small a quantity that it does not admit of precipitation by sulphuretted hydrogen, and no solid particles of arsenic are found in the stomach, in its contents, or in any article of food, another method may be resorted to for detecting its presence. This method equally applies to the detection of arsenic deposited as a result of absorption in the soft organs of the body, as in the liver, kidney, or heart, and to arsenic in all its forms, except the pure insoluble sulphide or orpiment. The substance, whether food, blood, mucus, the liver, or other organ, should be first thoroughly dried, either by exposure to a current of air or by a water-bath. The dried solid should then be broken into small portions and placed in a flask or retort of proper capacity, with a sufficient quantity of the strongest hydrochloric acid (free from arsenic) to drench it completely. After some hours' digestion in the cold, the retort or flask (*a*) containing the mixture

Fig. 9.

Apparatus for distilling organic and mineral substances containing arsenic.

—which should be of such a size that the materials should not fill it to more than one-third or one-half of its capacity—should be fitted with a long condensing tube (*c*), and then gradually heated by a sand-bath until the acid liquid begins to pass over. A metallic head, formed of a cone of tin plate, should be placed over the retort or flask so as to concentrate the heat and prevent condensation in the upper part of the vessel. A small flask receiver (*d*) with a loosely-fitting cork may be employed to collect the product. This should contain a small quantity of distilled water so as to fix and condense any vapors that may pass over. The receiver, as well as the condensing-tube, should be kept cool by wetting its surface with cold water diffused on a layer of blotting-paper placed over it. A perfect condensation of the distilled liquid is insured by this arrangement. This distillation may be carried to dryness on a sand-bath, or nearly so; and it may be sometimes advisable, in order to insure the separation of the whole of the arsenic as chloride, to add to the residue on the retort when cold, another portion of pure and concentrated hydrochloric acid, and distil to dryness. I have, however, found that portions of dried liver and stomach gave up every trace of arsenic by one distillation,

when a sufficient quantity of hydrochloric acid had been used, and the process was slowly conducted by a regulated sand-bath heat. By this process arsenic is at once separated from every metal excepting antimony, and these metals may be easily distinguished by tests applied to the distillate.

The liquid product may be colored, turbid, and highly offensive if distilled from decomposed animal matter. Exposure to the air for a few hours sometimes removes the offensiveness, and there is a precipitation of sulphur, or of some sulphide of arsenic. The distillate may be separated from any deposit by filtration, and if still turbid, it may be again distilled at a lower heat to separate it from any organic matter that may have come over. If there is a yellow deposit, it should be examined for sulphide of arsenic.

If arsenic is present in the substance submitted to distillation, the distillate will contain arsenic in the form of soluble chloride; this does not escape from a diluted solution at common temperatures. The quantity of dry organic substance used in the experiment must depend on the quantity of arsenic present, as revealed by a preliminary trial with Reinsch's process. If large, two or three drachms of the dried substance, or even less, will yield sufficient chloride of arsenic for further proceedings. For the absorbed and deposited poison, half an ounce of the dried organ, corresponding to two ounces of the soft organ, will frequently suffice; but a negative conclusion of the absence of arsenic should not be drawn from a smaller quantity than two to four ounces of the dried substance, whether liver, kidney, or heart. These tissues, it must be remembered, contain about 76 per cent. of water. If oily matters should be distilled over, this may be separated by passing the distillate through a paper filter wetted with water.

The distilled liquid, containing *chloride of arsenic*, should if clear be submitted to a further stage of analysis. For this purpose one-third of it should be diluted with three or four parts of water, and boiled in a clean flask. When boiling, a piece of bright copper-foil (free from arsenic), of about the size of the sixteenth of a square inch, should be introduced. If there is chloride of arsenic in the liquid, even up to the $\frac{1}{1000}$ th of a grain, its presence will be indicated by a change of color, and by the deposit of a dark metallic film on the copper. If the quantity of arsenic present is believed to be very small, the surface of copper introduced should be proportionately small. Bettendorff's process may be also employed for the detection of small quantities of arsenic in the distillate: Add to a solution of chloride of tin its bulk of fuming hydrochloric acid. Warm this mixture, and then add to it a few drops of the distillate. The presence and proportion of arsenic are indicated by a dark-brown precipitate consisting of reduced arsenic. (For an account of this test see Wigger's "Jahresbericht," 1871, p. 528.) The remaining two-thirds of the distilled liquid, sufficiently diluted, should now be introduced into a Marsh's tube, or into an evolution flask provided with a funnel-tube, the capacity of which must be regulated by the quantity of acid liquid to be examined. The kind of apparatus employed in this stage is represented in the engraving, Fig. 10. A the flask with funnel-tube B, and containing-piece c; the funnel-tube should be long enough

just to dip below the surface of the acid liquid. The short connecting piece is bent at a right angle, and, like B, is carried through a closely fitting cork in the neck of the flask. This tube should be only long enough to go through the cork, and its open end should be bevelled off to a fine point, so that any vapor which is condensed on it may fall back as liquid into the flask. D is the drying tube containing fragments of

Fig. 10.

Apparatus for testing chloride of arsenic obtained by distillation.

Fig. 11.

Portion of tube separated with a deposit of metallic arsenic in the contracted portion.

chloride of calcium, secured by cotton at both ends. At the flask end of this tube should be placed some well-dried bibulous paper, saturated with acetate of lead. This has the advantage of stopping any gaseous sulphur compound, which may escape from the zinc or acid liquid. E E, a hard and not easily fusible glass tube, free from lead, contracted in two situations K K', to about the diameter of the tenth of an inch or less, the tube itself having a diameter of from a quarter to three-eighths of an inch. F F are supports made of a stout wire, to prevent the tube from falling when heated to redness. G is a test glass to hold one or two drachms of a strong solution of nitrate of silver. H is a Bunsen's air gas jet, which gives a stronger heat than a spirit-lamp, although the latter may be used.

The arrangement being thus made, the zinc and hydrochloric acid are first tested as to their freedom from arsenic. Portions of pure zinc are placed in the flask A, the parts of the apparatus are then connected, and pure hydrochloric acid, diluted with three or four parts of water, is poured into the flask by the funnel B, which operates as a safety valve. Bubbles of air and gas speedily appear in the liquid in G, if the corks fit well and the whole of the arrangements are air-tight. Pure zinc is sometimes but imperfectly acted on by the acid. In this case some clean platinum wire or foil may be wound round the bars of the zinc, and the evolution of hydrogen will be thus accelerated. It is, however, better that the hydrogen should come off rather slowly. If the materials are pure, the solution of nitrate of silver should undergo no change of color. The glass G should be placed on a sheet of white paper, whereby the

slightest tinge of brown or black is made perceptible. When all the air is expelled from the tube, the smokeless flame H may be applied to it at about one inch in front of a contraction of the tube, as indicated in the engraving, and the glass heated to redness. No metallic deposit should take place at K. If the materials are quite pure, the transparency of the glass tube at K will be unchanged. From a quarter to half an hour will be sufficient for this experiment.

We may now add to the acid liquid in the flask A, a portion of the liquid obtained by distillation. The presence of arsenic in this will be immediately revealed by the silver solution in the glass G acquiring a brown or black color, according to the quantity of arsenic present, and at the same time deposits of metallic arsenic may be obtained by heating the glass tube E E.

The silver solution is allowed to become saturated with the gas. Any escape of the gas from the glass, or by leakage from any of the junctions of the apparatus, is at once indicated by holding near to the spot, filtering paper wetted with nitrate of silver. This is instantly blackened. The glass with the silver solution is removed, the end of the tube well washed, or another tube substituted for E E, and this is allowed to dip into about one drachm of the strongest nitric acid, containing much nitrous acid in a test-glass similar to G, or into a small porcelain capsule. After a time, the acid loses its color, and the metallic arsenic of the gas is converted into arsenic acid, which may be obtained by evaporation.

The further testing of the products is a very simple process. 1. The silver solution contains arsenic in the state of arsenious acid dissolved, with some excess of nitrate of silver. By one or two filtrations it is obtained colorless and clear. A weak solution of ammonia is then added to it, and yellow arsenite of silver is at once precipitated (see p. 143). The nitric acid liquid is evaporated to dryness in a small porcelain capsule. One or two drops of water are added to the residue, with a drop of weak ammonia if it should be very acid. A strong solution of nitrate of silver is then added to it; arsenate of silver, of its well-known brick-red color, immediately produced. 3. The portions of tube K K' with the metallic deposits in them may be separated by a file, and then hermetically sealed, or if necessary, one or more of them may be tested by the methods described in a preceding page.

It might be supposed that arsenic would escape as chloride in this method of operating, but when hydrochloric acid is diluted with six or eight parts of water, little or no volatile chloride is distilled over. In reference to the recent organs, a larger proportion of acid may be used, because three-fourths of the weight of the animal substance really consists of water.

With these results, the evidence of the presence of arsenic may be considered to be conclusive. The poison is obtained by this process, not only in its pure metallic state, but in the distinct forms of its too well-known oxides—arsenious and arsenic acids. Any demonstration beyond this is superfluous. It will be observed that Reinsch's process is here employed as an adjunct to Marsh's process in an improved form, in which the burning of the gas is unnecessary.

Reinsch's process alone may be employed for detecting arsenic, deposited as a result of absorption in the liver, kidneys, or other organs.

Fig. 12.

Flask employed
in the analysis of
arsenicals by
Reinsch's process

About four ounces of the recent organ, or more, if necessary, cut into small pieces, may be boiled in a flask in a mixture of one part of pure hydrochloric acid and four of water, until the structure of the organ is broken up. The flask may be of the shape represented in the annexed engraving, and either a naked spirit-flame or a sand-bath may be employed. A small glass funnel should be placed in the neck of the flask. This receives and condenses the vapor which falls back into the flask. By this arrangement the boiling may be continued for a long time, without material loss by evaporation. The flask should not be more than half full, and heated gently until all froth is expelled. A slip of fine platinum wire, having a small piece of pure copper-foil, should be immersed in the liquid when boiling. This enables the operator

to remove the copper and examine it at intervals, after immersing it in distilled water. If it is much coated with a metallic deposit, larger portions of copper-foil may be successively introduced until the liquid is exhausted. The deposit on the copper may then be tested by the method described on page 145.

It is remarkable for what a length of time the copper retains the arsenic deposited upon it. Some copper-gauze in which arsenic had been thus deposited was examined after twenty-five years, and, although much changed in appearance by exposure, it yielded a perfect sublimate of octahedral crystals.

I have not here described the various carbonizing processes which have been recommended by Orfila and other French medical jurists for the purpose of destroying organic matter. If M. Blondlot's observations are correct, they have been the source of great and unsuspected errors in medico-legal analyses—sometimes withdrawing the poison altogether, and sometimes causing it to reappear under circumstances which are liable to create a fallacy. (*"Annales d'Hygiène,"* 1861, 1, 152.)

It need hardly be observed that the *quantity of arsenic found in the stomach* or other organs can convey no accurate idea of the quantity actually taken by the deceased, since more or less of the poison may have been removed by violent vomiting and purging, as well as by absorption and elimination. A large quantity found in the stomach or bowels indicates a large dose; but the finding of a small quantity does not prove that the dose was small. Notwithstanding these very obvious causes for the removal of a poison from the body, there is a strong prejudice among lawyers that the chemical evidence is defective unless the quantity found is sufficient to cause death. It would be just as reasonable, in a case in which a man has been killed by a discharge of small shot, to insist upon a failure of proof of the cause of death, because only a single pellet has been found in the body. The value of chemical evidence does not depend on the discovery of any particular *quantity* of poison in the stomach—it is merely necessary that the evidence of its presence should be clear, distinct, conclusive, and satisfactory. At the same time, a reasonable

objection may be taken to a dogmatic reliance upon the alleged discovery in a dead body of minute fractional portions of a grain; and, considering the great liability to fallacy from accidental presence of arsenic in the articles used, the chemical evidence in the French case of *Madame Laffarge* (1840), in which the whole quantity discovered in the dead body was stated to be the hundred and thirtieth part of a grain, was of a most unsatisfactory kind, and should have been rejected by the court. No man with any respect for his character, or for the common sense of a jury, would base chemical evidence on the thousandth, or less than the thousandth, part of a grain of poison in a case of life and death; although, for the purpose of procuring the acquittal of a criminal, he may safely boast of his alleged power to detect this, or even a smaller quantity.

If a person has died with arsenic in the body, there is scarcely any limit to the period at which it may be detected. In the cases of two children examined by Mr. Herapath, in July, 1849, the poison was discovered in the remains of the dead bodies after eight years' interment; in another case by Dr. Glover after twelve years ("Lancet," July 9, 1853, p. 41); and in a remarkable instance which occurred to Dr. Webster, of Boston, it was discovered in the remains of a body, after fourteen years' burial in a tomb. It has been sought for, and not found, at much shorter periods after death when there was a very strong suspicion that the poison had been taken: but it is highly probable that in these cases there was little or no arsenic in the bodies at the time of death. The longer a person has survived after taking this poison, the less probable is it, *cæteris paribus*, that arsenic will be found in the remains.

The *condition* of the arsenic found in a dead stomach should be specially noticed. A witness should be prepared to say whether it is in fine powder or in coarse fragments; whether it is mixed with soot or indigo; or whether it is in the ordinary state of white arsenic. These points may be material as evidence in reference to proof of possession, of purchase, or administration.

Arsenic is *not* a normal constituent of the body. Under no circumstances is it found in the tissues after death, except in cases in which it has been taken or administered.

ARSENITE OF POTASH. LIQUOR ARSENICALIS. (FOWLER'S SOLUTION.)

Symptoms and appearance.—In a case in which this solution destroyed life, a woman took half an ounce (= two grains of arsenic) in divided doses, during a period of five days, and died from the effects. There was no vomiting or purging, but after death the stomach and intestines were found inflamed. ("Provincial Journal," June 28, 1848, p. 347.)

A mixture of arsenic, soft soap, and tar-water is largely used in agricultural districts for killing the fly in sheep. This has caused death under the usual symptoms of arsenical poisoning in at least two instances. ("Annal. d'Hygiène," 1879, p. 470.)

This may be regarded as a case of acute poisoning. Although much used in medicine, it is not often that we hear of any fatal accidents from this

solution. Medicinal doses frequently taken without sufficient time being allowed for elimination, may, however, destroy life. The following case of chronic poisoning is reported in the "Revista Medica de Rio de Janeiro" for 1879. A Brazilian physician, æt. 50, suffering from some skin affection and occasional attacks of intermittent fever, having tried as a remedy sulphate of quinia without any effect, prescribed for himself Fowler's solution. He took twelve drops twice daily for three months. About this time he had a sudden fainting fit which alarmed him. He had previously felt pains in his knees, which he ascribed to rheumatism, and had suffered from vomiting, giddiness, and inability to stand, but he took no heed of these warnings. After three months, he consulted a physician. His pulse was then slow, irregular, and intermittent; his urine was diminished in quantity; he had no desire to pass it, and there was tenesmus about the bladder and rectum with colicky pains. He was advised to discontinue the arsenical solution; but in the course of two or three days he had another fainting fit in which he died.

Death was properly ascribed to chronic poisoning by arsenic (arsenicism). This physician had taken for twelve months one-tenth of a grain of arsenic twice daily, or a daily total of one-fifth of a grain. This would be equivalent to eighteen grains in three months. There is no doubt that he had died from the accumulation of arsenic in the system, as the result of insufficient elimination.

Analysis.—The solution has the odor of tincture of lavender, is of a reddish color, and has an alkaline reaction. One fluidounce of it contains four grains of arsenious acid. It gives at once a green precipitate (arsenite of copper) with the sulphate of copper, and a yellow precipitate with nitrate of silver. Acidulated with hydrochloric acid, and treated with a current of sulphuretted hydrogen gas, it yields a yellow sulphide; and when boiled with this acid and pure copper, a deposit is obtained which readily furnishes by heat octahedral crystals of arsenious acid.

FLY-WATER is a name applied to solutions of various arsenical compounds in water. Mixtures of this kind are formed by dissolving one part of the arsenite of soda or potash and two parts of sugar in twenty parts of water. Paper soaked in this solution, and dried, is used for killing flies under the name of *Papier Moure*; and perhaps this is the safest form in which arsenic can be used for such a purpose.

ARSENITE OF COPPER. SCHEELE'S GREEN. EMERALD GREEN.

This is the only metallic arsenite which is met with in commerce and the arts, and it constitutes, wholly or in part, a great variety of green pigments employed for paper-hangings, known as Emerald green (aceto-arsenite of copper), Mineral green, Brunswick, Schweinfurt, Vienna, or Paris green. It is also found in the form of oil-paint, of cakes in boxes of water-colors, spread over confectionery, in wafers, in adhesive envelopes, in wrappers for chocolate, isinglass, etc., and lastly and most abundantly, in various kinds of green decorative papers used for covering the walls of sitting and bedrooms.

Although this compound is insoluble in water, it is sufficiently soluble

in the acid mucous fluids of the stomach to be taken up by the absorbents, and carried as a poison into the blood. M. Roussin has traced the means by which this insoluble poison finds its way through the skin, and the circumstances under which it may be absorbed by the unbroken skin. In two cases which proved fatal in 1865, the workmen suffered chiefly from vomiting, and colicky pains. The skin was tinged of a green color, and arsenic was detected in the soft organs. He found that all poisons were liable to be absorbed by the unbroken skin when as a result of evaporation a solid film was left on the surface. Alcohol and other solvents of fat, when used as solvents for the poisonous solid, would favor its absorption into the body. It requires no theory of idiosyncrasy to account for poisoning under such circumstances. ("Annales d'Hygiène," 1867, pp. 179, 182.)

In a case which was the subject of a criminal trial, this substance was proved to have caused the death of a gentleman by reason of its having been employed to give a rich green color to some blanc-mange served at a public dinner—the person who employed it considering that emerald or mineral green was nothing more than an extract of spinach! It led to death under the usual symptoms, and the parties were convicted of manslaughter and sentenced to imprisonment. (*Reg. v. Franklin and Randall*, Northampton Summer Assizes, 1848.)

The *symptoms* of poisoning which have been observed in persons who have inhabited rooms of which the walls were covered with this arsenical compound are as follows: Dryness and irritation of the throat with bronchial cough, irritation of the mucous membrane of the eyes and nostrils, languor, headache, loss of appetite, nausea, colicky pains, numbness, cramp, irritability of the bowels, attended with mucous discharges, great prostration of strength, a feverish condition, and wasting of the body. These symptoms may not all present themselves in any one case; they are derived from the examination of numerous cases which have been referred to me. No suspicion of the cause had been entertained until ordinary treatment had failed to impart relief, and an analysis of the paper had been made. The connection of the symptoms with this cause appears to have been in some instances clearly established by the fact that after the removal of the paper, especially from bedrooms, the symptoms have disappeared. (For illustrative cases, see "Brit. Med. Journal," Nov. 4 and 18, 1876, p. 653, also Jan. 6, 1877, p. 8.) It is, however, proper to observe that, as in reference to the manufacture of white lead, comparatively few of those who are exposed suffer from symptoms of poisoning. Various deaths, chiefly among children, from the use of this paper are now recorded, and it is probable that to the noxious practice of covering the walls of our sitting and bedrooms with large quantities of arsenic in loose powder, many insidious cases of illness and chronic disease may be referred. Men and women employed in the manufacture of these poisonous pigments suffer severely (see "Ann. d'Hyg.," 1847, 2, p. 56; 1859, 2, p. 107, and 1867, 2, p. 179). Dr. Kittel states that girls employed in making artificial green leaves, in which this substance is used in fine powder, suffer from inflammation of the conjunctivæ, with thickening and swelling of the eyelids ("Lancet," 1873, 1, p. 174). Children's toys are often colored with this poisonous

compound. In one case a child, æt. 5, was seized with sickness, diarrhoea, and great depression. The cause of these symptoms was traced to a box of counters colored bright green. The child had imbibed the poison, either by handling or putting the counter into its mouth.

The late Dr. Seaton has described the cases of a whole family in which all the usual symptoms of arsenical poisoning presented themselves as a result of their inhabiting rooms recently papered with a paper containing not more than one-sixth of a grain of Scheele's green in a square foot. On the removal of the paper the symptoms disappeared. ("Brit. Med. Jour.," Jan. 1880, p. 127.)

Several cases of poisoning by arsenical wall papers, some occurring in the Queen's rooms at Osborne, are described by Mr. Jabez Hogg. ("Brit. Med. Jour.," June 14, 1879, p. 891.) Dr. Ninemeyer states that he met with three cases of chronic poisoning with arsenic under similar circumstances, in persons employed in the court-house of Königsberg. The walls were covered with a green-colored dust, which was found to contain 8.32 per cent. of arsenious oxide. He attributes the chronic poisoning to the respiration of this dust. ("Ziemssen's Cyclopedia," vol. 17, p. 653.)

Analysis.—The wall-paper pigment called EMERALD GREEN is a mixture of arsenite and acetate of copper. The green color is very intense, even by candle-light. The presence of arsenic in this compound may be easily detected by all the tests for solid arsenic (page 143); but the following is a simple method which admits of speedy application: A slip of the suspected paper should be soaked in a moderately strong solution of ammonia. The green color is removed, and the blue ammoniuret of copper is formed and dissolved in a few minutes. This result establishes only the presence of a compound of copper soluble in ammonia. If the ammonia does not become blue, there is no compound of copper present; if it does become blue, a large crystal of nitrate of silver must be placed in a white saucer and a small portion of the blue liquid poured over it. The presence of arsenic is at once revealed by the production of yellow arsenite of silver over the surface of the crystal.

ARSENIC ACID. ALKALINE ARSENATES.

Arsenic acid is an artificial product almost entirely confined to the chemical laboratory. Orfila states that it is a more powerful poison than arsenious acid, but does not adduce any instance in support of this opinion. I have not been able to find any case of poisoning by it in the human subject. The arsenates of potash and soda must be regarded as active poisons, although there are but few instances on record in which life has been destroyed by them.

M. Bergeron has reported the case of a girl, aged seventeen, who died in five days from the effects of a large dose of *arsenate of copper* (Mittis green). The symptoms were incessant vomiting, purging, coldness of the surface, and collapse. It is remarkable that the mucous membrane of the alimentary canal presented no abnormal changes. That of the

stomach was pale. Arsenic was found in all the organs examined. ("Ann. d'Hyg.," Jan. 1880, p. 23.)

Analysis.—Arsenic acid is a white uncrystalline deliquescent solid. 1. It is very soluble in water, forming a highly acid solution. 2. It is precipitated of a brick-red color by nitrate or the ammonio-nitrate of silver.

SULPHIDES, OR SULPHURETS OF ARSENIC. ORPIMENT.

ORPIMENT or YELLOW ARSENIC owes its poisonous properties to the presence of a variable proportion of arsenious acid, sometimes amounting to as much as 30 per cent. of its weight. It is much employed in the arts, in painting, dyeing, paper-staining, and even in the coloring of toys and sweetmeats for children, but is not often used as a poison. Orpiment produces *symptoms* and *appearances* similar to those caused by arsenious acid; but the dose required to destroy life varies according to the proportion of arsenious acid with which it happens to be mixed. This is not a common form of poisoning; the yellow color of the poison would lead to suspicion; but by reason of this color, orpiment may be given or taken by mistake for mustard or turmeric.

Analysis.—The powdered sulphide yields a solution of arsenious acid on boiling it in water acidulated with hydrochloric acid. It readily gives the well-known sublimates of metallic arsenic, either with soda-flux or ferrocyanide of potassium (see p. 141). Boiled in strong nitric acid, it is converted into arsenic acid.

CHLORIDE OF ARSENIC.

This is a solution of arsenic in diluted hydrochloric acid. It was formerly used in pharmacy, but is now excluded. It contains one grain and a half of arsenious acid in one fluidounce, which is equal to the small proportion of three-sixteenths of a grain to a fluidrachm. Mr. Phillips states that it is a highly poisonous preparation, and from a case which I saw in Guy's Hospital in May, 1857, this statement is confirmed. A woman took, in three doses, thirty minims over a period of twenty-four hours. The quantity of arsenic thus taken was not more than the *tenth part* of a grain, and yet the symptoms which followed were of a severe kind, resembling those of chronic poisoning. These were constriction of the throat, pain and irritation of the stomach and bowels, tingling and numbness of the hands and feet, loss of muscular power, and a feeling of extreme depression. The medicine (a poison) was withdrawn, and the patient slowly recovered. It seems that she had not taken arsenic previously, and there was no evidence of the existence of a peculiar susceptibility to the effects of arsenic. The quantity taken was very small to produce such alarming symptoms. The usual medicinal dose of this solution is from three to ten minims.

Analysis.—This compound is the product obtained in the separation of arsenic from organic solids by distillation with hydrochloric acid (see page 146). It may be tested by the process of Marsh or Reinsch, as

there described. When boiled with fuming chloride of tin, it is decomposed, and metallic arsenic of a brown-black color is deposited.

ARSENURETED HYDROGEN.

This is a gaseous poison of arsenic, producing, when respired even in small quantity, very serious effects upon the system. It has caused death in four instances among chemists who have incautiously breathed the deadly vapor while performing scientific experiments. Dr. Trost, of Aachen, has reported three other fatal cases, with a full account of the symptoms and appearances. These cases occurred accidentally among workmen engaged in separating silver from lead by means of zinc and hydrochloric acid. The latter was found to contain much arsenic which escaped with the hydrogen. ("Vierteljahrs.," 1873, 1, p. 269. See "ON POISONS." "Chemical News," Dec. 26, 1863, p. 307.)

The symptoms produced are vomiting, with pain in the region of the stomach and headache, combined with prostration. Dr. Naunyn describes among the symptoms abundant urenio-globinuria (bloody urine), the arsenuretted hydrogen having the property of decomposing the blood-globules.

Dr. Waechter, of Altona, describes four cases of this form of poisoning arising from the use of arsenical sulphuric acid for producing hydrogen. The men breathed the gas which accidentally escaped while they were filling small India-rubber balloons with hydrogen. One died while the others recovered. ("Ann. d'Hyg.," 1879, 1, p. 286.)

CHAPTER XII.

POISONING BY MERCURY.—CORROSIVE SUBLIMATE.—SYMPTOMS.—CHRONIC POISONING.—APPEARANCES AFTER DEATH.—CHEMICAL ANALYSIS.—PROCESS FOR MERCURY IN ORGANIC LIQUIDS.—CALOMEL.—WHITE AND RED. PRECIPITATES.—OTHER COMPOUNDS OF MERCURY.

METALLIC MERCURY is not commonly regarded as a poison. It is usually stated that a large quantity of it may be swallowed without affecting health, or without causing more uneasiness than that which may arise from its great weight. It rapidly passes through the bowels. A case which lately occurred to Sir D. Gibb shows that this is not strictly true. For the purpose of causing abortion, a girl swallowed four and a half ounces of mercury by weight. It had no effect on the uterus, but in a few days the girl suffered from a trembling and shaking of the body (mercurial tremors) and loss of muscular power. These symptoms continued for months, but there was no salivation and no blue mark on the gums. ("Lancet," 1873, 2, p. 329.) If mercury is breathed or swallowed in a state of *vapor*, or if applied to the skin or mucous membrane in a state of extreme mechanical division, in which state it appears to be

easily susceptible of oxidation, it is liable to be absorbed, and to produce a poisonous action on the body. The effects are principally manifested by salivation, trembling, and involuntary motions of the limbs, loss of appetite, and emaciation. These symptoms are occasionally seen in workmen engaged in trades in which they are exposed to the inhalation of mercurial vapors.

CORROSIVE SUBLIMATE.

This substance has received a variety of chemical names. It has been at various times called *Oxymuriate*, *Chloride*, *Bichloride*, *Mercuric Chloride*, and *Perchloride of Mercury*. To prevent any confusion from scientific chemical nomenclature, the old and popular name of *Corrosive Sublimate*, expressing the principal properties of the substance, is here retained. It is commonly seen under the form of heavy crystalline masses, or of a white crystalline powder. Its *taste* is powerfully austere and metallic, so that no poisonous quantity of it could be easily swallowed, without the person becoming immediately aware of it. It is very *soluble* in water, hot or cold, and speedily sinks in it, in which properties it differs strikingly from arsenic. [It also readily dissolves in alcohol and ether.—R.]

Symptoms.—The symptoms produced by corrosive sublimate generally come on immediately, or within a few minutes after the poison has been swallowed. In the first place there is perceived a strong metallic taste in the mouth, often described as a coppery taste; and there is, during the act of swallowing, a sense of constriction almost amounting to suffocation, with burning heat in the throat, extending downwards to the stomach. In a few minutes violent pain is felt in the abdomen, especially in the region of the stomach, which is increased by pressure. There is nausea, with frequent vomiting of long stringy masses of white mucus, mixed with blood, attended with severe pain in the abdomen, and profuse purging. The countenance is sometimes swollen and flushed, in other cases it has been pale and anxious. The pulse is small, frequent, and irregular, and is scarcely perceptible when the symptoms become aggravated. The tongue is white and shrivelled,—the skin cold and clammy, the breathing difficult; and death is commonly preceded by fainting, convulsions, or general insensibility. The internal parts of the mouth, when examined, are swollen, and sometimes present a white appearance, as if the cavity had been washed with a solution of nitrate of silver; the lips are often swollen. Suppression of urine has been frequently noticed among the symptoms: it existed in a well-marked case of poisoning by this substance at Guy's Hospital:—the patient lived four days, but did not pass any urine during the whole of this time. (“Guy's Hospital Reports,” April, 1844, p. 24.) This symptom was observed in a case reported by Dr. Wegeler (Casper's “Wochenschrift,” Jan. 10, 1846, p. 30), in which a youth, æt. 17, swallowed three drachms of the poison and died on the sixth day. During the last three days no urine was secreted. The case was otherwise remarkable from the fact that no pain was experienced on pressure of the abdomen, and that the pulse underwent no change until shortly before death. In another case, reported by

the late Dr. Herapath, in which a scruple of corrosive sublimate in solution was swallowed, suppression of urine and salivation came on on the third, and the patient died on the ninth day. ("Lancet," Dec. 13 and 27, 1845, pp. 650, 698.)

The *external* application of corrosive sublimate to tumors or ulcers may destroy life with all the usual symptoms of acute mercurial poisoning. At the Winchester Lent Assizes, 1859 (*Reg. v. Crook*), a quack was convicted of manslaughter by applying corrosive sublimate in powder to a cancerous tumor in the face of deceased. The man died under the usual symptoms. After death the bowels were found extensively inflamed and ulcerated. Mr. May, of Reading, detected corrosive sublimate in the diseased parts. At the Exeter Lent Assizes, 1878, a quack doctor (by trade a harness maker), was indicted for the manslaughter of a woman under similar circumstances. The deceased had ulcers in her legs, and a solution of corrosive sublimate largely diluted, was applied by the prisoner in order to cure them. The death of the woman was assigned to the absorption of the poison; but the learned judge held that gross and culpable ignorance had not been proved, and under his direction the prisoner was acquitted. In September, 1871, a girl, æt. 9, died from the effects of this poison, locally applied to the scalp for the treatment of ringworm. The liquid applied was alcohol containing eighty grains of corrosive sublimate to the ounce! She suffered from mercurial poisoning in a severe form, and died on the fifth day after the application. This case is instructive to medical men. (See "Pharm. Jour.," Sept. 9, 1871, p. 216; "Lancet," 1871, vol. 2, p. 473; and "Med. Times and Gazette," 1871, vol. 2, p. 353.) No theory of idiosyncrasy is required to account for death under such circumstances. In the first edition of my work ON POISONS (1848), p. 394, fatal cases are related of poisoning by corrosive sublimate through the unbroken skin. Two brothers thus lost their lives, the one dying on the fifth, and the other on the eleventh day. Those who deny the power of the unbroken skin to absorb corrosive sublimate and cause all the usual effects of acute mercurial poisoning, should make themselves, and not their patients, the subjects of experiment. Severe salivation sometimes follows the external application of a mercurial compound. A man suffering from eczema of the scrotum was directed to employ black wash, consisting of one drachm of calomel in eight ounces of lime-water. In a few days he had fetor of the breath, swelling and tenderness of the gums, with salivation. ("Brit. Med. Jour.," March, 1878, p. 367.)

This poison differs from arsenic: 1, in having a well-marked taste; 2, in producing violent symptoms in a few minutes; and, 3, in the fact that the evacuations are more frequently mixed with blood. The symptoms produced by corrosive sublimate, in the first instance, resemble those of cholera; if the person should survive several days, they are more like those of dysentery,—violent straining, and shreddy mucus mixed with blood, being frequently observed.

Slow or chronic poisoning.—The symptoms are much modified when the poison is taken in small doses at intervals for some days or weeks. There are colicky pains with nausea, vomiting, general uneasiness, and depression. The salivary glands become inflamed and painful; the

tongue and gums are red and swollen, sometimes ulcerated, and there is fetor of the breath. A deep blue line, like that observed in poisoning by lead, is sometimes found around the edge of the gums. The patient experiences difficulty of swallowing and breathing. The constitutional effects are indicated by irritability or looseness of the bowels, difficulty of breathing, spitting of blood, cough, general trembling or convulsive movements of the limbs and palsy, with fever and emaciation, under which the patient sinks. One of the most marked effects of slow or chronic poisoning by mercurial preparations is *salivation*, or ptyalism, indicated by an increased flow of saliva. This is by no means a necessary symptom in cases of acute poisoning by corrosive sublimate, but it not unfrequently shows itself about the second or third day. In many instances the patient dies too rapidly for this effect to follow; but even when he survives some days, salivation is not always observed. In placing reliance upon this symptom, it must be remembered that salivation may arise from a variety of causes irrespective of the use of mercury. (See "Poisons," 3d ed., p. 366.) Substances sold under the name of *Worm Lozenges* have been known to cause death by producing fatal salivation. In the salivation caused by mercurial compounds the saliva always contains mercury, which may be detected by Reinsch's process. The elimination of this metal takes place by all the secretions, but chiefly by the urine and intestinal liquids. ("Lancet," 1873, vol. 1, p. 476.)

Appearances after death.—These, as in the case of arsenic, are chiefly confined to the stomach and bowels. Corrosive sublimate, however, affects the mouth, throat, and gullet; the mucous membrane is softened, of a white or bluish-gray color, and sometimes inflamed; that lining the gullet is similarly affected, and partly corroded and softened. The mucous membrane of the stomach is more or less inflamed, sometimes in patches; and there are masses of black extravasated blood found beneath it. Occasionally this has a slate-gray color, and the mucous coat beneath may be found reddened. A case occurred in Guy's Hospital, in which the mucous membrane was simply inflamed: it much resembled the condition presented in cases of arsenical poisoning. The coats of the stomach are sometimes corroded, and so much softened that they cannot be removed from the body without laceration. Similar appearances have been met with in the small and large intestines, especially in the cæcum. In a case reported by the late Dr. Herapath, in which a scruple was taken, and death occurred on the ninth day, the mucous membrane of the stomach was softened, but there were no well-marked appearances of the irritant action of the poison on this organ. The cæcum had been the seat of the most violent inflammation, the whole surface being of a deep black-red color, and there were patches of sloughing in the coats. ("Lancet," Dec. 27, 1845, p. 700; "Edinburgh Monthly Journal," Dec. 1851, p. 532.) Perforation of the stomach is rare as an effect of this poison: there is, I believe, only one case on record. Appearances like those just described, have been seen in the intestines, not only where the case has terminated fatally in a few hours, but where it has been protracted for six, eight, and even eleven days.

The *smallest* dose which is reported to have destroyed life is *three grains*. This was in the case of a child, and the quantity was accurately

determined from the fact that its having been made up by mistake for three grains of calomel, which a physician had intended to order. It is probable that, under favorable circumstances, from three to five grains, or even less, would destroy an adult.

In an acute case a person commonly dies in from one to five days, but death may take place much sooner or later than this. In the shortest fatal case on record the man died in less than *half an hour*, but the quantity of poison taken was not ascertained. ("ON POISONS, CORROSIVE SUBLIMATE.")

Chemical analysis.—Corrosive sublimate is usually seen in heavy crystalline masses, or in the form of a white powder. In the *solid state*—1. When the powder is heated on platinum foil or mica, it melts, and is volatilized in a white vapor without leaving any residue. 2. When heated in a close tube, unlike arsenic, it melts before subliming, and forms a sublimate consisting of stellated prismatic crystals. (See Fig. 13.)

Fig. 13.

Stellated crystals obtained by heating corrosive sublimate, magnified 30 diameters.

Fig. 14.

Prismatic crystals of corrosive sublimate from a solution in water, magnified 30 diameters.

3. The powder is changed in color by the following reagents: iodide of potassium produces a bright scarlet, potash a yellow, and sulphide of ammonium a black compound; ammonia does not alter its color. 4. The mercury and chlorine may be discovered by one process. Mix the powder with four parts of dried carbonate of soda (obtained by incinerating the bicarbonate), until the residue in the reduction-tube fuses and becomes white. A sublimate of metallic mercury in distinct and well-defined globules will be obtained. Detach by a file the end of the tube containing the fused residue, which is chloride of sodium with some undecomposed carbonate. Digest it in water with nitric acid, and apply heat until it is entirely dissolved: then add to the solution nitrate of silver. A white precipitate of *chloride* of silver, insoluble in nitric acid, will be at once produced. The solid is thus proved to contain both mercury and chlorine, and the only compound of these elements which is soluble in water is corrosive sublimate.

In *solution in water*. A few drops of the solution of corrosive sublimate evaporated on a glass-slide yield slender opaque silky prisms. When a weak solution of iodide of potassium is dropped on them, they acquire a bright scarlet color. This scarlet coloration, which may be obtained from the minutest crystal and only one drop of solution, proves that

the body dissolved in water is corrosive sublimate: it is thus distinguished from every other mineral poison, and all other substances whatever. 1. Chloride of tin added to a solution of corrosive sublimate produces a black precipitate, which, after it has been boiled, is resolved into globules of metallic mercury. 2. Sulphuretted hydrogen and sulphide of ammonium produce, after a time, a black sulphide, not soluble in alkalies or dilute acids. 3. If after the liquid has been acidulated with hydrochloric acid, bright copper-foil, wire, or gauze, is plunged into it, the copper will acquire a silvery-white deposit, even in the cold, but more rapidly by heat. When the copper with the metallic deposit is dried and heated in a tube, globules of mercury are sublimed. (See Fig. 15.)

Fig. 15.

Globules of mercury.

In organic liquids.—The liquids should be separated by filtration from any insoluble portions. The latter should be pressed, dried, and set aside for a separate analysis. The liquid portion should be slightly acidulated with hydrochloric acid, warmed, and a slip of copper foil or gauze introduced; if this is not immediately coated with mercury, it may be allowed to remain for some hours. When a deposit has taken place on the copper, it should be removed, washed in water, and afterwards in ether and dried. If the quantity of corrosive sublimate dissolved in an organic liquid is moderately large, it may be removed by means of ether. Place the filtered liquid supposed to contain the dissolved poison, in a stoppered tube: add to it twice its volume of pure ether, and agitate the liquid at intervals for a few minutes. Allow the liquid to subside, pour off the ether into a dial-glass, and submit it to spontaneous evaporation. As the ether passes off, the corrosive sublimate will be deposited in white silky-looking prisms. These may be purified, if necessary, by solution in water or alcohol, and the solution again crystallized. Corrosive sublimate may thus be separated from arsenic and other mineral poisons in solution. If mercury and arsenic are associated in a poisonous mixture, or in the tissues, the arsenic may be entirely removed by distillation (page 146). Masses of corrosive sublimate may be sometimes locked up in thick viscid mucus; and in such cases, the coarse powder being heavy, it may be separated by simply agitating the viscid liquid in water, and then decanting the upper portion suddenly. This poison is decomposed and precipitated by many organic principles, such as albumen, fibrin, mucous membrane; also by gluten, tannic acid, and other vegetable substances. Thus, then, we cannot always expect to find it in the stomach, in a state of solution. Other methods of analysis are chiefly directed to the separation of the mercury only. The suspected liquid is boiled, filtered, and acidulated with hydrochloric acid. 1. To one portion add chloride of tin in excess, again boil the liquid and filter to separate the mercury, the whole of which is precipitated either as a black powder, or in gray globules. On boiling the deposit in strong hydrochloric acid, the small globules coalesce to form

liquid mercury. 2. Into another portion of the liquid, introduce copper gauze, foil, or wire, and gently warm it. The copper is covered with a layer of silvery white metal, either immediately or in a few hours. A large quantity of copper may be thus coated. The coated copper should be digested in warm alcohol or ether, dried and heated in a reduction-tube, when a sublimate in silvery-white globules will be obtained, well marked by their capacity, lustre, and sphericity when examined by the microscope. (See Fig. 15.) The sublimate of metallic mercury differs from that of arsenic in the fact that, when heated, it sublimes simply as metal without change. It is not oxidized (like metallic arsenic) by heating it in a reduction-tube, but is simply transferred with its metallic lustre and globular form from one part of the tube to another. In the event of a doubt existing respecting the nature of the sublimate, the following experiment will remove it. Cut off by a file the portion of glass on which the globules are deposited: introduce this into a wide short tube, with a few drops of hydrochloric and half the quantity of nitric acid. Heat the acid liquid, and evaporate it to dryness on a sand-bath. White prismatic crystals of corrosive sublimate will remain, if the sublimate is of a mercurial nature, and too great a heat has not been applied. On touching the white residue cautiously with a drop of solution of iodide of potassium, the crystals will acquire a scarlet-red color. In place of copper, a slip of gold foil may be wound round a slip of zinc foil, and introduced into the liquid. The gold is soon covered with a silvery-white layer of mercury, which may be separated from it by heat in a reduction tube, or by the action of nitric acid, and the nitrate thus formed may be subsequently tested by the chloride of tin.

The tissues, etc.—The *urine* may be evaporated to dryness, and the dry residue or extract treated by the following process, which is the same as that required for the *tissues*. From four to eight ounces of the liver or other organs should be dried, broken up, and then boiled until dissolved in one part of pure hydrochloric acid and four parts of water. The acid liquid may be strained through linen, and the residue pressed. The liquid, if in large quantity, should now be concentrated by gentle evaporation, and while still slightly warm, a small piece of copper-gauze (proved to be free from mercury) should be introduced, at the end of a fine platinum wire, into the acid liquid. The copper may acquire a white, gray, or silvery tarnish in a few minutes, or not until after twenty-four hours. It may be removed, washed in water and alcohol, and dried and examined by low power of the microscope. The deposition of any white metal on the copper will then be perceptible. It may be rolled into a pellet and heated in a dry reduction-tube, when minute globules may appear as a sublimate. The sublimate in the tube should be examined with a microscope, and the copper should in all cases be heated, whether the red color of this metal appears to be covered or not by any deposit. (See Fig. 15.)

If arsenic should be present in the tissues at the same time, and the acid mixture is boiled, arsenic and mercury will be deposited together; and when the copper is heated, the globules of mercury will be obtained nucleated or intermixed with octahedral crystals of arsenious acid. In a case of exhumation after twenty-one months' burial, these mixed sub-

limates were obtained by the examination of the rectum of the deceased. (*Reg. v. Bacon*, Lincoln Summer Assizes, 1857.) It appeared in evidence that arsenic had been administered to the woman a day or two before death, and a dose of calomel had been prescribed more recently. This accounted for the presence of the mixed sublimate.

Arsenic is not readily deposited on copper in the cold, while mercury is readily deposited, at all temperatures, from acid liquids. We may sometimes take advantage of this difference in chemical properties, to obtain a separate deposit of this metal.

In the living body, mercury is eliminated by the *saliva* as well as by the urine. About one drachm of this fluid will suffice for the detection of mercury by the following process. Acidulate the saliva with one-fourth of its volume of pure hydrochloric acid. Immerse in this a portion of copper gauze, about the sixteenth of an inch square, attached to a fine platinum wire. Place the tube containing the liquid in a warm place for a few hours. If mercury is present in the saliva, the copper gauze will be whitened. Other portions may then be introduced until the mercury ceases to be deposited. The pieces of copper should be washed in water and ether, and dried; examined by a low power of the microscope, and then heated in a small reduction-tube. Globules of mercury visible under the microscope will then be obtained. In a case of inunction with mercury the metal was thus detected in the saliva on the third day. There was painful swelling of the salivary glands, with the peculiar metallic taste produced by mercury. This analysis of the saliva may not only furnish evidence that the person is under the influence of mercurial poison, but it will prove, in a case otherwise doubtful, whether the *salivation* from which a person is suffering is owing to mercury or some other cause. An examination of the saliva should be made in other cases of metallic poisoning, as arsenic, antimony and other metals might be thus detected in the act of elimination from the living body.

The analysis may show the presence of *mercury*, but not of corrosive sublimate, in the body. Whether the mercurial compound had acted as a poison or not, must be determined from symptoms and appearances. Whether it had been given or taken as a medicine or not, is a conclusion which must also be determined from other circumstances. The proof that the mercury was really in the form of corrosive sublimate could only be derived from the discovery of some undissolved portions of the solid poison in the stomach or its contents, or from a separation of the poison itself by means of ether. If thus obtained after filtration of an organic liquid, it would show its presence in the form of a soluble salt; and it may be remarked that all the soluble salts are poisonous, and are rarely used internally as medicines. If undissolved, the absorbed mercury may have been derived from some mercurial medicine innocently taken by the deceased. Nothing is more common than to discover traces of mercury in the stomach, bowels, liver, kidneys, or other organs of a dead body. No importance can be attached to this discovery, in the absence of evidence that the deceased has actually suffered from symptoms of mercurial poisoning. As to the mercury found in the *tissues*, it may have been derived from a soluble or insoluble compound, or from exposure to the vapors of the metal or of its salts, in various trades.

CALOMEL. *Subchloride of Mercury.*—This substance, although commonly regarded as a mild medicine in small doses, may destroy life by causing excessive salivation with ulceration and gangrene; and in large doses it acts as an irritant poison.

Analysis.—It is known from corrosive sublimate by its insolubility in water, alcohol, and ether. It is known from white precipitate by its insolubility in acids, and by its being blackened by alkalies. A mercurial sublimate may be obtained from it by heating it with dry or anhydrous carbonate of soda. Under certain conditions, this compound may be changed into corrosive sublimate in the stomach. (“Pharm. Journ.,” Aug. 31, 1878, p. 164.)

WHITE PRECIPITATE. *Ammoniated Mercury.*—The symptoms which this compound produces are violent vomiting, cramps, great thirst, purging, and pain in the stomach and bowels, with convulsions. Tenderness of the gums and salivation have been observed among them. After death there is more or less inflammation of the stomach and bowels. Experiments on dogs and rabbits have shown that this is a formidable poison. The greater number of recoveries have been probably owing to the substance being early ejected by vomiting. Rabbits, which do not vomit, were killed by a dose of four and five grains in a few hours. After death, mercury was found deposited in various organs, but more in the kidneys than in the other viscera. (For additional facts connected with the action of this poison see “Guy’s Hosp. Reports,” October, 1860, p. 483.) A trial for attempting to poison by this substance took place at the Maidstone Summer Assizes, 1869 (*Reg. v. Seaham*). The compound is white, but as the result of boiling, it gave a yellow color to the gruel in which it was administered. In *Reg. v. Hargreaves* (Manchester Lent Assizes, 1866), a girl was convicted of an attempt to poison her father by this substance. The poison was put into milk and medicine. It produced a burning sensation in the throat and stomach, and thus led to suspicion. About ten grains of white precipitate were detected in some buttermilk.

This substance is very easily procured by children. In February, 1873, a boy of 12 was convicted at the Central Criminal Court of administering this poison feloniously in medicine. The prosecutor experienced a hot sensation, unlike the bitter taste he had before perceived. A white powder was found in the medicine which proved to be white precipitate.

Analysis.—White precipitate is a chalky-looking compound containing about eighty per cent. of mercury. It is insoluble in water and alcohol. As it is sold in the shops it frequently contains, as an impurity, corrosive sublimate to the amount of one or two per cent., separable by ether or alcohol. It is not used internally, but it is much employed by the poorer classes in the treatment of ringworm. It is soluble in acids, is not blackened by alkalies, and it yields a mercurial sublimate when heated with carbonate of soda. Chloride of tin produces with it a black deposit of mercury. If boiled in a solution of potash, it evolves ammonia, and yellow oxide of mercury is precipitated. It may be detected in organic liquids and solids by boiling them in one part of hydrochloric acid and four parts of water. The mercury may then be separated by means of copper.

RED PRECIPITATE. *Red Oxide of Mercury.*—This substance is poisonous, but instances of poisoning by it are very rare. In a case which occurred at Guy's Hospital the patient recovered in four days. In June, 1878, a woman, æt. 20, swallowed a quantity of beer containing red precipitate. Four hours after she was seen by Mr. Smyth of the Cumberland Infirmary. She was in a state of stupor, with a weak, irregular, scarcely perceptible pulse, pupils dilated, skin cold and clammy, copious discharge from the mouth. She had vomited once shortly before, and red particles were seen in the ejected fluid. There was pain in the abdomen. Under treatment the symptoms abated, but there was pain in the region of the stomach, a desire to vomit, much salivation, and slight diarrhoea. She gradually recovered. ("Brit. Med. Journ.," July 20, 1878, p. 101.)

Analysis.—By its great weight and insolubility in water, it may be separated from all liquids. Its red color identifies it. When heated in a close tube it is resolved into oxygen and mercury, which is deposited in globules.

Other compounds of mercury, such as the *nitrates*, *sulphates*, the *cyanide*, *sulpho-cyanide*, and *sulphide*, have given rise to accidents, and in a few instances have destroyed life, but they rarely require the notice of a medical practitioner.

When heated in a dry state with anhydrous carbonate of soda, all the compounds of mercury yield sublimates of the metal in globules. All liquid and solid compounds give a dark precipitate of mercury when boiled with the acid chloride of tin.

CHAPTER XIII.

ON POISONING WITH LEAD.—SUGAR OF LEAD.—SYMPTOMS.—APPEARANCES AFTER DEATH.—CHEMICAL ANALYSIS.—LEAD IN ORGANIC MIXTURES.—CARBONATE OR WHITE LEAD.—CHRONIC POISONING.—POISONING WITH COPPER.—BLUE VITRIOL.—SYMPTOMS.—APPEARANCES.—CHEMICAL ANALYSIS.—COPPER IN ORGANIC LIQUIDS.

SUGAR OF LEAD.

Acetate of Lead. Symptoms.—Acetate or sugar of lead is by no means an active poison. In medical practice it has often been given in considerable doses without any serious effects resulting. When from one to two ounces have been taken, the following symptoms have been observed: a burning, pricking sensation in the throat, with dryness and thirst, vomiting, and uneasiness at the pit of the stomach, followed by severe colic. The abdomen is tense, and the skin covering it is sometimes drawn in. The pain is relieved by pressure, and has intermissions. There is generally constipation of the bowels. If any feces are passed they are commonly of a dark color, indicative of the conversion of a

portion of the lead into sulphide. The skin is cold, and there is great prostration of strength. When the case is protracted, the patient has been observed to suffer from cramp in the calves of the legs, pain in the inside of the thighs, numbness, and sometimes paralysis of the limbs. The affection of the nervous system is otherwise indicated by giddiness, torpor, and even coma. A well-marked blue line has been noticed round the margin of the gums, where they join the teeth. For a remarkable series of cases of poisoning by acetate of lead, reported by Mr. Banks of Stourbridge, see "Lancet," May 5, 1849, p. 478.

Appearances.—In one fatal case of acute poisoning the mucous membrane of the stomach was destroyed in several places, especially near the intestinal opening; and most of the intestines were in a state of acute inflammation. In animals, according to Dr. Mitscherlich, when the dose is large, the mucous coat of the stomach is attacked and corroded; this change appears to be purely chemical, and takes place in those parts of the body with which the salt of lead comes in contact. If given in a small dose, it is decomposed by the gastric secretions, and exerts no corrosive action on the mucous membrane. When the acetate of lead was given in a state of albuminate dissolved in acetic acid, death took place with great rapidity; but on inspection, the stomach was not found corroded. This corrosive action belongs to the neutral salt, and is not manifested when the dose is small, or when the poison is combined with an acid. Nothing is actually known concerning the *fatal dose* of this substance; but it may be taken in comparatively large quantity without producing serious effects. Thirty or forty grains have been given daily in divided doses without injury.

Chemical analysis. Acetate of lead as a solid.—1. If a portion of the powder is heated in a small reduction-tube, it melts, then becomes solid: again melts, acquiring a dark color, and gives off vapors of acetic acid, easily recognized by its odor and reaction on litmus paper. A black mass is left in the tube, consisting of carbon and reduced metallic lead. No sublimate is formed. If heated on mica, yellow oxide of lead with reduced metal remains. 2. It is very soluble in water, even when cold; spring water is turned milky by it, from the presence of carbonic acid and sulphates. 3. A small portion of the powder dropped into a solution of iodide of potassium acquires a bright yellow color. 4. When dropped into solution of potash it remains white. 5. Into sulphuretted hydrogen water or sulphide of ammonium, it is turned black, in which respect it resembles the white salts of some other metals. 6. When the powder is boiled in a tube with diluted sulphuric acid, acetic acid, known by its odor and volatility, escapes. All these properties taken together, prove that the salt is the acetate of lead.

Acetate of lead in solution.—1. A small quantity, slowly evaporated on a glass slide, will give slender white prismatic crystals, which are turned yellow by iodide of potassium, and black by sulphide of ammonium. 2. *Diluted sulphuric acid* produces an abundant white precipitate, insoluble in nitric acid, but soluble in hydrochloric acid and in a large excess of potash. 3. It is precipitated of a yellow color by the *iodide of potassium*; the yellow iodide of lead is soluble in potash, forming a colorless solution. It is also dissolved by concentrated hydrochloric acid. 4. *Sul-*

phide of ammonium, or sulphuretted hydrogen gas, produces a deep black precipitate, even when less than the 100,000th part of the salt is dissolved. 5. Place a few drops of the solution on clean platinum-foil,

Fig. 16.

Fig. 17.

Crystals of acetate of lead, magnified
80 diameters.

acidulate it with acetic acid, then apply through the solution, to the surface of the platinum, a thin slip of polished zinc—dark bluish crystals of metallic lead are instantly deposited on the zinc: by this method, a small quantity of the metal may be detected and separated.

Lead in organic liquids.—The acetate of lead is precipitated by many organic principles, especially by albumen and tannic acid. Thus, we may have to analyze either an organic liquid containing lead, or a solid precipitate consisting of mucus or mucous membrane, or albumen intimately united to oxide of lead. The liquid should be filtered and examined by a trial test, *i. e.*, either by adding to a portion, sulphuric acid, when sulphate of lead is precipitated, or by exposing bibulous paper, dipped into the suspected liquid, to a free current of sulphuretted hydrogen gas. If the paper is not stained brown, there is no perceptible quantity of lead dissolved; if it is stained brown, we dilute the liquid to destroy its viscosity, should this be necessary, and pass into it a current of washed sulphuretted hydrogen gas until all chemical action has ceased. The black sulphide of lead should be collected on a filter, washed, and dried; then boiled for a quarter of an hour in a mixture of one part of nitric acid, diluted with four parts of water. This has the effect of transforming it, at least in part, into nitrate of lead soluble in water. This liquid, when filtered, may be evaporated to dryness, the crystalline residue dissolved in water, and the tests for lead then applied to the solution. If the quantity is too small for the application of all the tests, we may first add sulphuric acid; should a white precipitate be formed, soluble in potash (free from oxide of lead), and this alkaline solution be again turned black by sulphide of ammonium, this is sufficient evidence of the presence of lead. Should there be no lead dissolved, we must decompose the solid and insoluble matters by boiling them in nitric acid slightly diluted, filter, and test the filtered liquid, previously neutralized; or we may evaporate at once to dryness, destroy the organic matter by heat, and redissolve the residue in nitric acid for testing.

In the tissues.—The organic matter, such as a part of the liver or other organ, should be *dried*, and afterwards incinerated in a porcelain vessel. The ash should be heated with a small quantity of strong nitric acid, and evaporated to dryness. The dry residue should be digested in a small quantity of distilled water (free from lead), filtered, and, after it has been slightly acidulated with nitric acid, a current of washed sulphuretted hydrogen gas should be passed into it. The production of a brown color or a brown precipitate in a slightly acid liquid indicates the presence of lead. Lead may thus be detected in the dry residue of urine and of spring or river water. All liquid and solid organic substances containing lead, yield the metal or its oxide by incineration in a porcelain capsule.

There is reason to believe that absorbed lead is in combination with albumen; hence it cannot be dissolved out of an organ, but can be separated only by the destruction of the organic matter. Herschel found that the proportion of the metal which was accumulated in different organs was subject to great variation. In experiments on dogs poisoned by the administration of the acetate of lead for several weeks, the largest proportion was found in the bones, 0.025 per cent. Other organs presented the following proportions per cent.: the kidneys, 0.012 to 0.02; liver, 0.01 to 0.016; spinal marrow, 0.006 to 0.01; the brain, 0.004 to 0.005; muscles, 0.002 to 0.003; coats of the intestines, 0.002; and lastly, in the lungs and blood as a rule, no traces could be detected. (“Ziemssen’s Cyclopædia,” vol. 17, 1878, Poisons.) MM. Leloir and Pouchet detected lead in the brain and kidneys of a saturnine patient three months after he had ceased to work in lead, but not in the liver or spleen. (“Ann. d’Hyg.,” 1879, 1, 183.)

Goulard’s Extract is a solution of subacetate of lead, the oxide of the metal being in excess; and *Goulard Water* is a mixture of one drachm and a half of this solution with a pint of water. The effects of these compounds when swallowed or applied locally are similar to those produced by the acetate.

WHITE LEAD. *Carbonate of Lead.*—This is an insoluble, chalky-looking compound, which, like other salts of lead, may give rise to the usual symptoms of lead-poisoning. In one instance it appears to have proved fatal. White lead has been used as a cosmetic to give a fair complexion. It is liable to absorption, and to cause the usual symptoms of poisoning. The cosmetic liquid of Madame Rachel consisted of a lead compound with Fuller’s earth, starch, and hydrochloric acid. Such a compound applied to the skin clearly would set up irritation in the skin, and be most injurious to health. Most of the cases of poisoning by this substance have been of a chronic character, carbonate of lead being one of the products of the action of water upon lead.

Chronic poisoning.—*Colica pictonum*, or *Painter’s Colic*, may be considered as the chronic form of poisoning by carbonate of lead. The *symptoms* are usually well marked. There is at first pain with a sense of sinking commonly in or about the region of the navel (the seat of the colon). Next to pain there is obstinate constipation, retraction of the skin of the abdomen, loss of appetite, thirst, fetid odor of the breath, and general emaciation, with paralysis of a peculiar kind affecting the

extensor muscles, and causing a dropping of the wrist, or showing itself in a general paralysis of the limbs. The skin acquires a sallow color, generally well marked in the face; and the patient experiences a sweetish, styptic, or astringent taste in the mouth. A symptom of a peculiar nature was first pointed out by the late Dr. Burton ("Med. Gaz.," vol. 25, p. 687), namely, a *blueness* of the edges of the *gums*, where these join the bodies of the teeth; the teeth are of a brownish color. The blue line on the gums may be regarded as a distinguishing sign of lead-colic. It is owing to the deposition of lead in these structures, a fact proved by the action of chromic acid on the excised gums. They acquire a yellow color (chromate of lead), and when afterwards treated with an alkaline sulphide, they become black from the production of sulphide of lead. ("Lancet," June, 1878, p. 913.)

Hairwashes generally contain a salt of lead in solution. The use of them may lead to all the symptoms of chronic lead-poisoning.

Chronic poisoning with lead often kills the patient, since a great amount of mischief is usually done before the cause is discovered. The *appearances* found after death have been a contraction of the cavity of the large and small intestines, and a considerable thickening of their coats. These changes have been especially noticed in the colon—the seat of colic. The various circumstances under which this form of poisoning is liable to occur, are elsewhere fully described. (See "On Poisons," p. 409.)

One of the most frequent causes of chronic lead-poisoning is the use of water kept in leaden cisterns or pipes, or the careless employment of white or red lead as a cement for pipes and cisterns. For an instructive series of cases showing the effects of water thus poisoned, I must refer the reader to a paper by Dr. de Mussy, published in the "Dublin Quarterly Journal" for May, 1849; also "Medical Gazette," vol. 44, p. 260. These cases occurred at Claremont, among the members of the ex-Royal Family of France. The effects were traced to the use of pure water which had acquired an impregnation of lead by contact with that metal, in the proportion of one grain to the imperial gallon. Thirteen out of thirty-eight persons were affected, and to such a degree that the nails of the toes and fingers in some acquired a bluish discoloration. The children of the family did not suffer. This is perhaps the smallest quantity of lead in water accurately recorded to have produced the effects of poisoning. No symptoms appeared until after the water had been in use for a period of from five to seven months, and more than half of those who used the water escaped any ill effects.

Cases of poisoning are sometimes observed as the result of the accidental introduction of *oxide of lead* into the system through wine, beer, cider, milk, lemonade, and other liquids. All liquids allowed to stand for some hours in leaden vessels or pipes, will acquire a noxious impregnation from lead, especially if they are slightly acid. Dr. Hewett met with the case of a barman employed at a large hotel, which will serve to illustrate this fact. This man was the first downstairs in the morning, and he had been accustomed to draw and drink beer from an engine which had not been turned off or exhausted at the cellar on the previous night. After pursuing this practice for a week, he experienced a sweet-

ish astringent taste, and suffered from uneasiness in the bowels. The symptoms increased, and after three weeks from the commencement of his engagement at the hotel, he suffered from lead colic and paralysis in the arms. There was a well-marked lead line in the gums. On analysis of the contents of one of the lead pipes, lead was found in the beer in the proportion of 0.26 grain in a gallon. Earthenware glazed with litharge imparts oxide of lead to fat in dripping, also to acid liquids. Snuff is sometimes adulterated with *red lead*, to improve its color, and some cases of lead-poisoning have occurred from the use of such snuff. The old penny postage stamps owed their red color to this noxious compound. Another color which does not expose the public to the risk of lead-poisoning has been recently substituted.

A spurious tin-fold, consisting chiefly of lead faced with tin, is much used as a covering or wrapper for articles of food. When exposed to damp, this metallic alloy undergoes chemical changes whereby carbonate of lead is produced. Children's farinaceous food has thus become impregnated with carbonate of lead. In tinned iron vessels there is often a large quantity of lead combined with the tin, as it is a much cheaper metal. Dr. Hamilton has noticed that lead-poisoning has been produced in India, by the use of the tinned cooking pots. ("Lancet," Feb. 1877, p. 253.)

There is another unsuspected method by which lead may find its way into that common article of food, corn flour. It is sometimes a custom of millers to repair the holes in their millstones with melted lead. The lead is thus carefully ground into and mixed with the flour. Dr. Alford states that fifteen or twenty persons, in different families, suffered from colic, and other symptoms of chronic lead-poisoning, from this cause. The blue line on the gums was well marked. It was found that they had all had their own corn ground at the same mill. On examining the millstones, they were found to be honey-combed with lead. There was on the surface of the stones about ten pounds of lead. ("Brit. Med. Jour.," May 19, 1877, p. 627.) This method of impregnating flour with lead has been fully illustrated by the late M. Chevallier. ("Ann. d'Hyg.," 1879, 1, 128.)

[During the year 1866, whole families in one of the counties of the State of New York were poisoned by the use of flour manufactured at a mill, the owner of which had been in the habit of filling the cavities in the millstones with lead.—P.]

POISONING WITH COPPER.

All the salts of copper are poisonous. The two most commonly known in commerce are the SULPHATE or BLUE VITRIOL; and the SUB-ACETATE or VERDIGRIS.

BLUE VITRIOL. Sulphate of Copper. Symptoms.—Sulphate of copper has been frequently given for the purpose of procuring abortion. In doses of half an ounce and upwards, it acts as an irritant on adults, and a much smaller quantity would suffice to destroy infants or children. The salt speedily causes vomiting of the most violent kind; this sometimes expels the poison from the stomach, and the person recovers.

There is headache, with pains in the abdomen and purging; the pain is of a colicky character, and in aggravated cases there are spasms of the extremities and convulsions. Dr. Percival met with an instance in which violent convulsions were produced in a young woman by two drachms of the sulphate of copper. Paralysis, insensibility, and even tetanus have preceded death, when the poison was administered to animals. Among the symptoms occasionally met with in the human body, may be mentioned jaundice. This has been observed to attend poisoning by the sulphate, as well as by Scheele's green. In May, 1877, two children, one eight and the other six years old, ate a quantity of wheat which had been washed in a solution of sulphate of copper. They were seized with incessant vomiting, the vomited matter being of a bluish or greenish color. The vomiting continued more or less for several days. There was no purging. The elder child recovered, but the younger was very much prostrated, and died about two months afterwards. ("Brit. Med. Journ.," Sept. 1, 1877, p. 292.) The *vomited* matters are remarkable for being generally of a *blue* or *green* color; broken crystals of blue vitriol were discovered in them, in a case in which the poison was taken in the state of coarse powder. If the green color of the vomited liquid is owing to altered bile, it will not acquire a blue tint on adding to a portion of it a strong solution of ammonia; but if caused by a salt of copper, this change of color will serve to indicate the fact. The medicinal dose of sulphate of copper as an emetic is from five to fifteen grains, and as a tonic from one to three or four grains. *Verdigris*, or subacetate of copper, in large doses, produces similar symptoms.

Chronic poisoning by copper is occasionally seen among workers in this metal and its salts. The poison enters the system partly by the lungs in the form of dust, and partly by the skin in handling the metal or its salts. The marked symptoms are a coppery taste in the mouth, giddiness, pain in the bowels, vomiting, occasional diarrhœa, and wasting of the body. Dr. Clapton has pointed out another symptom; namely, a green line on the margin of the gums. He met with this in a sailor and in some working coppersmiths. ("Med. Times and Gazette," June, 1868, p. 658.) Two of these cases I saw in 1868. The green line was well marked. The men brought with them a hammer used in their work. It had a greenish color, and this was proved by tests to be owing to copper. The perspiration from the hands in working had converted the copper into subchloride, and had thus led to its absorption by the skin. Several cases of chronic poisoning by copper among coppersmiths have been treated by Dr. Cameron of Liverpool, but this symptom is not noticed. ("Med. Times and Gazette," 1870, 1, 581.)

[Poisoning by *bronze-powder* (an alloy of copper in very fine powder), used for printing in gold, is not an infrequent occurrence. The powder is dusted over the prepared size, and as it more or less mixes with the atmosphere of the apartment, it must consequently be inhaled into the lungs. An instructive case is quoted in the "Phila. Med. News and Abstract," Sept. 1880, from the "Brit. Med. Journ.," July 24, 1880, of a boy aged 13, who died from inhaling bronze-powder in a printing establishment. He suffered from sickness, pain in the bowels, great distension, and tenderness on pressure; no diarrhœa. He fell into collapse,

and died on the twelfth day after commencing the work, and the eighth day of his sickness. Death was found to have resulted from peritonitis; no inflammation of stomach or bowels. Dr. Tidy detected copper in the stomach and liver. R.]

Appearances.—In the few fatal cases which have been hitherto examined, the mucous membrane of the stomach and intestines has been found more or less thickened and inflamed, and in some cases eroded and softened. The gullet has presented an inflammatory appearance. In one case of poisoning by verdigris the stomach was inflamed and thickened, especially towards the intestinal opening, the orifice of which, from the general thickening, was almost obliterated. The small intestines were throughout inflamed, and perforation had taken place, so that part of the green liquid was effused into the abdomen. The large intestines were distended in some parts, and contracted in others, and the rectum was ulcerated on its inner surface. (Orfila, "Toxicologie," vol. 1, p. 623.) The lining membrane of the intestines has been found throughout of a deep green color, owing to small particles of the copper salt (verdigris) adhering to it.

Chemical Analysis.—The salts of copper, whether in the solid state or in solution, are generally known by their blue or green color. *Tests:* 1. *Solution of ammonia:* this gives, in a solution of a salt of copper, a bluish-white precipitate, which is soluble in an excess of the test, forming a deep violet-blue liquid. 2. *Ferrocyanide of potassium* gives in a very diluted solution a rich claret-red precipitate. If the quantity of copper is small, the liquid acquires merely a light-red color; if large, the precipitate is of a deep red-brown color, and of a gelatinous consistency. The ferrocyanide of potassium will act on the violet-blue solution produced by ammonia, provided it is diluted, and a few drops of diluted sulphuric acid are added in order to neutralize the ammonia. One portion of the liquid may thus be tried with the two tests. 3. *Sulphuretted hydrogen gas*, or sulphide of ammonium, gives a deep chocolate-brown precipitate, even in an acid solution; or, if the copper is in small proportion, merely a light-brown color. 4. A slip of *polished iron* (a common needle) suspended by a thread in the liquid slightly acidulated with sulphuric acid is speedily coated with a red layer of copper, even when the salt is in very small proportion. The iron thus coated may be washed, immersed in ammonia, and exposed to air. The liquid becomes slowly blue. Half a grain of sulphate of copper dissolved in sixteen ounces of water may be thus easily detected. 5. *The Galvanic test:* If a few drops of the copper-solution are placed on platinum-foil, slightly acidulated with a diluted acid, and the platinum is then touched through the solution with a slip of zinc-foil; metallic copper, of its well-known red color, is immediately deposited on the platinum. When the quantity of copper is very small, there is merely a brown stain; but a blue liquid is formed by pouring on it ammonia, and exposing it to air. A coil of fine platinum and zinc wires may be substituted for the foil.

Copper in organic liquids.—The oxide of copper is liable to be precipitated by certain organic principles, *e. g.*, albumen, fibrin, and mucous membrane; but some of these organic compounds are easily dissolved by acids, or even by an excess of the solution of cupreous salt. A portion

at least of the salt of copper is, therefore, commonly held dissolved. In such cases the liquid is usually of a *greenish color*, and has a strong coppery or metallic taste, even when the copper-salt is in far less than a poisonous proportion. Having filtered the organic liquid, let a portion of it be placed in a clean platinum capsule. A few drops of diluted sulphuric acid should be added, and a slip of zinc-foil be introduced. Whenever the platinum is touched by the zinc, metallic copper is deposited; and, after having in this way coated the platinum capsule, the surplus liquid may be poured off and the capsule well washed out. The deposited copper, which is of a deep red color, is then dissolved in nitric acid, and the tests are applied after the excess of acid has been driven off by heat, and the residue dissolved in water. In place of nitric acid and heat, a strong solution of ammonia may be poured on the metallic deposit in the cold. Under exposure to air the metal is oxidized and dissolved in a few minutes, forming a blue solution. The ammoniacal solution may be neutralized with diluted sulphuric acid, and the ferrocyanide of potassium then applied. The red color of the deposit on the platinum is characteristic of copper, but the mode of testing here advised, renders the result conclusive.

In the tissues.—Dry and incinerate the organic matter. Digest the residuary ash in pure hydrochloric acid by heat, and then evaporate nearly to dryness. This residue may be dissolved in a small quantity of water, and a polished needle immersed in it for some hours. The metallic deposit, if any on the needle, may be recognized as copper, either by its color, or by the action of ammonia.

Traces of copper have been found in many kinds of food as well as in the tissues of the body, irrespective of the introduction of a copper-salt as a poison. Thus copper has been detected in various green pickles, in preserved peas and other vegetables. It has been used in these cases as an artificial coloring. In many prosecutions under the Adulteration Act, the question has arisen whether the quantity of copper (0.28 grain in a pound) would render the article injurious as food. Copper is a noxious substance, and there should be a penalty on its willful admixture with any article intended for food, whatever the proportion may be. This must be a matter of accident, and entirely beyond the control of the vendor. Thus, in some cases, Dr. Mutter found one and a half grains in a pound of peas. If a non-poisonous dose of white arsenic improved the appearance of cream, this would be no justification for its introduction into this article of food, nor any reasonable answer to the charge of selling food containing a poisonous ingredient. At any rate the peas, if legally sold, should be distinctly labelled—"Peas with copper."

The coloring of peas and other vegetable substances with copper has been fully examined in its medico-legal and sanitary aspects by Prof. Armand Gautier in the "*Annales d'Hygiène*," January, 1879, p. 5.

The use of copper culinary utensils either not tinned or badly tinned has been a frequent source of poisoning. Dr. Naunyn attributes the greater number of cases of copper-poisoning to this simple cause. In the Vienna General Hospital there were one hundred and thirty cases of poisoning caused in this way, nine of which were fatal ("*Ziemssen's Cyclopædia*," vol. 17, p. 590). In spite of these facts there are some "experts" who still maintain that copper is not a poison under any circumstances.

CHAPTER XIV.

TARTAR EMETIC.—SYMPTOMS.—APPEARANCES.—CHRONIC POISONING.—CHEMICAL ANALYSIS.—CHLORIDE OR BUTTER OF ANTIMONY.—POISONING WITH SALTS OF ZINC AND IRON.

TARTAR EMETIC.

Stibiated tartar. Tartarated Antimony. Symptoms and effect. When tartar emetic is taken in a poisonous dose, a strong metallic taste is perceived in the mouth during the act of swallowing. There is great heat with constriction of the throat, and difficulty of swallowing, violent burning pain in the region of the stomach, followed by incessant vomiting, profuse purging, faintness, and extreme depression. The pulse is small and rapid, sometimes imperceptible; the skin cold, and covered with a clammy perspiration; and the respiration is painful. Should the case prove fatal, death may be preceded by giddiness, insensibility, and prostration of strength, and sometimes violent spasms of the muscles of the limbs, which may assume either a clonic or a tetanic character. Such are the symptoms in an acute case of poisoning by this substance. The *quantity* actually required to destroy life is unknown. One dose taken at a dose proved fatal in ten hours in spite of early and frequent vomiting. ("Med. Gaz.," vol. 45, p. 801.) In a case in which a woman took a teaspoonful of tartar emetic by mistake, recovery took place in three weeks. She suffered from enteritis, and, as an after-effect, a hair fell off. ("Brit. Med. Jour.," Oct. 1876, p. 492.) A man took eighty grains. There was only slight vomiting an hour after he took it, but this became subsequently very violent, attended with severe cramps in the legs, and profuse perspiration. He recovered in two days. ("Brit. Med. Jour.," June, 1877, p. 674.)

Appearances.—The following cases show the nature of the appearances likely to be found after death: Two children, a boy aged five years and a girl aged three years, each swallowed a powder containing *grains* of tartar emetic mixed with a little sugar. It was stated that in twenty minutes after taking the powders, they were seized with violent vomiting and purging, and great prostration of strength, followed by convulsions and tetanic spasms; there was also great thirst. The boy died in eight hours, and the girl in twelve or thirteen hours, after swallowing the dose. The bodies were inspected between four and five days after death. In that of the boy there was effusion of serum in the pleura; the lower lobe of the right lung posteriorly was redder than natural, and the peritoneum was injected from recent inflammation. The mucous membrane of the duodenum was inflamed, and covered with a whitish-yellow viscid secretion; this was observed throughout the intestine.

tines, but the color was of a deeper yellow in the large intestines: there was no ulceration. The peritoneal coat of the stomach was inflamed. The mucous membrane of this organ was also much inflamed, especially about the larger curvature and at the cardiac orifice: there was no ulceration, but in one case there was a patch of lymph. The stomach contained about two ounces and a half of a dark bloody fluid, having a slightly acid reaction. The tests used did not indicate the presence of antimony. With regard to other appearances, the tongue was covered with a white fur, and appeared soddened; the throat was not inflamed; the windpipe and gullet had a natural appearance. On opening the head the dura mater was found congested; the longitudinal sinus contained a coagulum of lymph, and but little blood. The vessels of the surface of the brain were much injected with dark-colored blood, the whole surface having a deep purple color. Every portion of the brain, when cut, presented many bloody points. The cerebellum and medulla oblongata were also congested; there was no effusion in the ventricles or at the base of the brain. In the body of the girl the morbid appearances were similar: there were, in addition, on the arms, legs, and neck, patches resembling the eruption of scarlatina. The arachnoid membrane was more opaque than usual; and on the mucous membrane of the stomach, where the inflammation was the greatest, were two or three white spots, each about the size of a split pea, which appeared to be the commencement of ulceration. ("Lancet," April 25, 1846, 460.)

Dr. Ranke met with a case in which a man took, in two separate doses, fifteen grains dissolved in water. This led to vomiting and purging, with pain in the abdomen. He died suddenly about six hours after the first dose. No antimony could be detected in the stomach or intestines. It seems that no attempt was made to detect absorbed antimony. ("Friedreich's Blätter der ger. Med.," July, 1879, p. 241.)

An extraordinary trial for murder by alleged poisoning with this substance took place at Annapolis, U. S., in December, 1871. *Mrs. E. Wharton* was charged with poisoning her friend *General Ketchum*. The trial lasted fifty-two days, and an astonishing amount of scientific evidence was brought forward for the prosecution and defence, apparently owing to the high social position of the parties, for there is nothing, medically speaking, in the case itself that might not have been settled in forty-eight hours. The General died after a short illness, but the symptoms, taken as a whole, bore no resemblance to those observed in poisoning with antimony; and but for the alleged discovery of twenty grains of tartar emetic in the stomach after death, no suspicion of poisoning would have probably arisen. (See "Guy's Hospital Reports" for Oct. 1857, in which thirty-seven cases of poisoning by antimony are recorded.) The appearances in the body proved nothing for or against antimonial poisoning, and some physicians of experience deposed that the symptoms and appearances were consistent with disease affecting the membranes of the brain and spinal marrow. On examining the chemical evidence, it appears that the process by sulphuretted hydrogen alone was employed, and a red-brown sulphide, resembling that of antimony in chemical properties, was obtained; but the quantity obtained as sulphide was only four-tenths of a grain, estimated as equivalent to

eight-tenths of a grain of tartar emetic. Thus, the chemical analysis brought out only a fraction of a grain, not amounting to one-twentieth part of the quantity said to be present; and no separation of antimony in the metallic state was made to corroborate the inference drawn from the precipitate produced by sulphuretted hydrogen. No chemical results were produced in court, although twenty grains would have allowed of the production of *metallic* antimony in a few minutes by copper, tin, zinc, and platinum, or by Marsh's process. The evidence that antimony was really there was not satisfactory; and that twenty grains were present in the stomach was wholly unproved. The chemical evidence does not, therefore, conflict with the pathological evidence, for it failed to show with clearness and distinctness the presence and proportion of poison said to have been found. The jury upon such weak evidence properly acquitted the prisoner. ("Report of Trial of Mrs. E. G. Wharton on the Charge of Poisoning Gen. W. S. Ketchum," Dec. 1871, Jan. 1872, in "Baltimore Gazette;" "American Journ. Med. Sci.," April, 1872, p. 329.)

In cases of *chronic poisoning* by this substance, the principal symptoms are as follows: Great nausea; vomiting of mucous and bilious liquids; great depression and prostration of strength; watery purging, followed often by constipation of the bowels; small, contracted, and frequent pulse; loss of voice and muscular strength; coldness of the skin, with clammy perspiration; and death from complete exhaustion. In these cases antimony may be detected in the urine by Reinsch's process. There are several cases reported which show that tartar emetic has been thus criminally employed. In the case of *Mr. Bravo* (May, 1876), the evidence showed that the symptoms and appearances were such as this poison would produce, and ten grains of tartar emetic were found in the stomach of deceased. Owing to the imperfect manner in which the first inquest was conducted, and the refusal on the part of the coroner to receive medical evidence, a second inquest was held. The result, however, was not satisfactory. The cause of death was clearly made out, and traced to the action of this poison. The jury came to the conclusion that this had arisen neither from suicide nor accident, but that the deceased had been wilfully murdered. There was not sufficient evidence to fix the guilt upon any person or persons. This case shows in a striking manner the inadequacy of the coroner's inquest to detect a crime, or the perpetrator of a crime. (See "British Med. Journal," May 20, 1876, and August 19, 1876.)

It has been hitherto supposed that the cases in which this poison has proved fatal have been few; but I have elsewhere reported thirty-seven, of which sixteen were fatal. The smallest fatal dose was in a child, *three-quarters of a grain*, and in an adult, *two grains*; but in this instance there were circumstances which favored the fatal operation of the poison. ("Guy's Hospital Reports," October, 1857.)

Chemical analysis. Tartar Emetic as a solid.—In the state of powder it is white and crystalline. 1. It is easily dissolved by water; it is taken up by fourteen parts of cold, and two of boiling water; the solution has a faint acid reaction, and an acrid metallic taste. It is not very soluble in alcohol. 2. The powder dropped into sulphide of ammonium

is turned of a deep reddish-brown color, and is thereby known from other white metallic salts. 3. When heated in a reduction-tube, it is charred, but does not melt before charring, like the acetate of lead. The metal is partially reduced by the carbon of the vegetable acid, and the decomposed mass has a grayish-blue metallic lustre. No metallic sublimate is produced in this experiment by the heat of a spirit-lamp. 4. When boiled in water containing one-sixth of pure hydrochloric acid and metallic copper is immersed in the liquid, a gray deposit of antimony takes place on this metal. The color of the deposit is violet-red if the quantity is very small, but the deposit is black and pulverulent if very large. 5. The solution acidulated with one-tenth part of hydrochloric acid gives in the cold a black deposit on a surface of pure tin. A slip of pure tin-foil may be used in this experiment. This serves to distinguish antimony from arsenic, which, under these circumstances, produces no deposit on *pure* tin. On the other hand, tartar emetic and other antimonial compounds give no deposit when boiled with chloride of tin and fuming hydrochloric acid, unless arsenic is present as an impurity.

Tartar Emetic in solution.—On slowly evaporating a small quantity on a slip of glass, it will crystallize in *tetrahedra*, and in derivatives of the octahedron, Fig. 18. If obtained from a very diluted solution, this crystallization is confused, and resembles that of arsenic. 2. *Ferrocyanide of potassium* does not precipitate the solution, whereby tartar emetic is known from most other metallic poisons. 3. *Sulphuretted hydrogen gas* produces in the solution a reddish orange-colored precipitate, differing in color from every other metallic sulphide. This precipitate is not readily soluble in ammonia, or in tartaric acid, but it is dissolved in the dry state by strong hydrochloric acid.

In liquids containing organic matter.—Tartar emetic is precipitated by tannic acid in all its forms, but not readily by albumen or mucous membrane; therefore it may be found sometimes dissolved in the liquids of the stomach, and sometimes precipitated. These insoluble compounds of antimony are very soluble in tartaric acid; and thus, if there should be no antimony dissolved, it may easily be brought into a state of solution by means of this acid. The liquid, acidulated with tartaric acid, should be boiled and filtered. If it should be highly colored or turbid, it may be concentrated and submitted to the process of dialysis. The antimonial compound may thus be obtained in a clear solution. (See page 109.) A current of sulphuretted gas may now be passed into the whole or a portion of it until there is no further precipitation. The sulphide is collected, washed, and dried. If it is the sulphide of antimony, it will have an orange-red or brown colour, it will be insoluble in a solution of ammonia, and when dried will be dissolved by a small quantity of boiling hydrochloric acid (forming chloride of antimony) with

Fig. 18.

Crystals of tartar emetic magnified 30 diameters.

the evolution of sulphuretted hydrogen gas. The boiling should be continued for several minutes until the liquid is colorless. On adding this solution, if not too acid, to water, a white precipitate of oxychloride of antimony (powder of Algaroth or Algarotti, *Mercurius Vitæ*) falls down. This is characteristic of antimony. The white precipitate is soluble in tartaric acid. If the sulphuretted hydrogen is passed into a colored organic liquid, the orange-red color of the sulphide can be only well seen in the froth. [We can hardly regard this test as absolutely *characteristic* of antimony, unless *pure*, inasmuch as the colored precipitate which may often be obtained by the action of sulphuretted hydrogen on a simple acid solution of certain organic substances is more or less *soluble in boiling hydrochloric acid*; and this solution, when thrown into water, *will yield a white precipitate*.—R.]

A portion of the acid liquid may be introduced with pure zinc and sulphuric acid into a Marsh's tube or apparatus, like that described at p. 144. The gas which escapes at the jet produces black deposit on paper impregnated with a solution of nitrate of silver; but unless sulphur is present, it produces no change on paper impregnated with a salt of lead. When ignited, it burns with a pale yellowish-white flame, producing white fumes of teroxide of antimony. Porcelain, or glass depressed on the flame, receives a black deposit of reduced metallic antimony, with grayish-colored layers of oxide at the circumference. There is no metallic lustre, such as is produced by arsenic, under similar circumstances, but on examining the reverse side of the glass, a dim metallic lustre will be perceptible. This deposit, unlike arsenic, is not dissolved by chloride of lime. If a current of the gas is heated to redness in a glass-tube, a tin-white ring of metallic antimony will be deposited close to the heated spot. This is much more fixed than the deposit of arsenic, and cannot, like it, be resolved into a white sublimate of octahedral crystals. If the gas is made to pass through a small quantity of fuming nitric acid containing nitrous acid, it is decomposed, the antimony is peroxidized, and may be obtained as a white, insoluble residue on evaporation. A solution of nitrate of silver produces no change of color in this deposit: but if one or two drops of ammonia are added, there is a black precipitate of antimonide of silver.

The following method of detecting the metal when dissolved in any organic liquid, is based upon the principle by which copper and other metals may be detected under similar circumstances: 1. Acidulate a portion of the suspected liquid with hydrochloric acid, and place it in a shallow platinum capsule. Touch the platinum, through the acid liquid, with a slip of pure zinc-foil. Hydrogen is evolved, and wherever the metals come in contact, metallic antimony, in the state of a black powder, is deposited upon the surface of the platinum. The liquid should be poured off, and the capsule thoroughly washed with distilled water. This may be effected without disturbing the black deposit. This deposit should be heated with strong nitric acid, evaporated to dryness, the white residue dissolved in strong hydrochloric acid; and this solution, not too much diluted, may be precipitated by a current of sulphuretted hydrogen; a reddish-colored sulphide indicates antimony. If a portion of this hydrochloric acid solution is added to water, it may give a

precipitate of white oxychloride of antimony, soluble in tartaric acid, and this solution may be precipitated of an orange-red color by sulphuretted hydrogen. By this process antimony in small quantity may be detected in, and separated from, any liquid containing organic matter. If there is no deposit under these circumstances, a slip of zinc or tin-foil, with a layer of thin platinum-foil wound round it, should be suspended in the acid liquid sufficiently diluted, for some hours. If antimony is present it will be deposited on both metals in the form of a black powder.

In the tissues.—The antimony may be deposited in the organs in so small a quantity, that neither the sulphuretted hydrogen nor the galvanic process will yield any satisfactory results. The liver or other organ should be cut into small pieces, and boiled in a mixture of one part of hydrochloric acid and five parts of water. After some time, the liquid may be tested by introducing into it a slip of polished copper-foil free from antimony. If antimony is present in small quantity, the copper will acquire a reddish or violet-colored deposit on its surface: if in large quantity, the deposit will be gray with a metallic lustre, or sometimes in the state of a loose black powder. These deposits, when heated in a reduction-tube, do not yield octahedral crystals like those obtained from arsenic. A slip of pure tin-foil may be suspended in the cold acid liquid, so diluted that the hydrochloric acid forms only one-tenth part by measure. Either immediately, or in the course of a few hours, if antimony is present, the tin is covered with a black deposit of the metal. Antimony in the metallic state is so easily procured from a small quantity of material, by one or other of the above-mentioned processes, that on no account should this be omitted. The procuring of the metal may be made subsidiary to the procuring of the sulphide, as the metal can be easily oxidized and converted into sulphide, in a pure form, and obtained entirely free from organic matter. A reliance on a small quantity of a colored precipitate from sulphuretted hydrogen alone, without the production of the metal in some form, would be most unsatisfactory as chemical evidence. No chemist would rely upon the production of a yellow sulphide, as certain evidence of the presence of arsenic, unless he obtained the *metal* arsenic from that compound.

[It is undoubtedly quite as important, in a trial for alleged poisoning by antimony, that the *metal* should be produced in evidence, as it is in a case of arsenical poisoning. We see no reason why antimony should be made an exception to the general rule, which is observed in the cases of poisoning by mercury, arsenic, lead, zinc, copper, etc.—R.]

The separation of antimony from the tissues does not necessarily indicate that it has been criminally administered, or has caused death; but its presence there should be reasonably accounted for, as antimony may have been unlawfully administered. In several cases of suspected death from poison, deposits on copper, evidently of an antimonial nature, have been obtained from the liver or tissues. On inquiry it has been found that antimonial medicines had been taken shortly before death.

Chloride or Butter of Antimony.—This is a strongly corrosive poison by reason of the acid with which the antimony is combined. It has caused death in several instances. The symptoms and appearances resemble those produced by concentrated hydrochloric acid. It gives a

white precipitate when added to water. This is soluble in tartaric acid, and the solution is precipitated of an orange-red color by sulphuretted hydrogen gas.

POISONING WITH ZINC.

Sulphate of zinc. White vitriol. Symptoms and appearances. The symptoms produced by an over-dose of sulphate of zinc are pain in the abdomen, and violent vomiting, coming on almost immediately, followed by purging. After death, the stomach has been found inflamed. The sulphate appears to act as a pure irritant; it has no corrosive properties. This salt may cause death indirectly, as the result of exhaustion from violent vomiting, when an ordinary dose has been given to a person already debilitated by disease. In one case, a lady recovered after taking sixty-seven grains. ("Lancet," May 17, 1856.) In another, which occurred in May, 1872, communicated to me by Dr. Mackintosh, of Downing, a man, æt. 20, recovered in a few days after taking an ounce of sulphate of zinc by mistake for Epsom salts. There was early vomiting and purging of a most violent kind, with great prostration of strength. The greater part of this large dose was no doubt thus carried out of the body.

In cases of epilepsy, the late Dr. Babington gave sulphate of zinc in doses of two scruples, three times a day, having first commenced with small doses. No ill effects followed, and none of the usual symptoms of irritation were observed. This may have been owing to a tolerance of the medicine. With respect to the *oxide of zinc*, Dr. Marcet states that he has prescribed it in large doses without injury to health. One patient, an epileptic, took as much as one pound in seven months, the largest quantity taken in one day being seventy grains. Although he did not suffer from the remedy, the disease was not cured. ("Lancet," March 1, 1862, p. 224.)

Chloride of zinc. Symptoms and appearances.—This, which is commonly sold under the name of "Sir W. Burnett's fluid," is a corrosive poison, and is much used as a deodorizer. The patient experiences a sense of heat and burning in the mouth and throat, in the act of swallowing the liquid, which has been frequently fatally mistaken for fluid magnesia. There is a burning and griping pain in the stomach, nausea, followed by violent retching and vomiting—the vomited matters being streaked with blood and mixed with much flaky mucus, with shreds of mucous membrane. This has produced an appearance of frothiness about the mouth. Violent purging has been observed among the symptoms. A stage of collapse supervenes, and the skin becomes cold and livid.

After death from this poison, the lining membrane of the mouth and throat has been found white and opaque; that of the stomach has sometimes been hard and leathery, at others, corrugated, opaque, and of a dark leaden color. The lungs and kidneys are congested. The chloride is both a corrosive and irritant poison, exerting also a peculiar action on the nervous system. If a person survives the acute stage, he may die in the chronic stage from stricture of the gullet or pylorus, or from emacia-

tion and exhaustion, as a result of the local action of the poison on this organ.

Analysis.—In these two compounds, the zinc is detected by the aqueous solutions giving white precipitates with a current of sulphuretted hydrogen gas, while the sulphuric acid or chlorine may be recognized by their respective tests.

Metallic zinc may be obtained by plunging into a weak solution of the salt a slip of magnesium.

Zinc can be detected in the *tissues* only by incineration, and an examination of the ash. The chloride is, however, sometimes used for the preservation of the dead body. This might account for its occasional presence.

PREPARATIONS OF IRON.

Sulphate of iron. Copperas. Green vitriol.—This compound has been several times administered with malicious intention. One death from it took place in 1837–8. It cannot, however, be an active preparation, for a girl who swallowed an ounce of it recovered, although she suffered for some hours from violent pain, vomiting, and purging. (“Christison on Poisons,” p. 506.) Green vitriol, or copperas, is sometimes given as an abortive. At the Nottingham Autumn Assizes, 1859, a woman of the name of *Riley* was indicted for administering copperas to two children. She put the substance into gruel. It gave to the gruel a greenish color and a peculiar taste, which led to the discovery. It caused sickness, but no other serious symptoms. As there was no evidence of an intent to murder, and it was then not unlawful to administer poison with any other intent, the prisoner was acquitted. This salt has been much used for criminal purposes in France. (See “Medical Gazette,” vol. 47, p. 307; also “Ann. d’Hyg.,” 1850, vol. 1, pp. 180, 416; and 1851, vol. 1, p. 155; vol. 2, p. 337.)

Muriate of iron. Tincture of perchloride of iron.—This is an acid solution of perchloride of iron in rectified spirit; it is a red-brown color, and is much employed as a medicine. It is sometimes made with wood-spirit, or methylated spirit, which gives to it a peculiar odor. Sir R. Christison relates an instance in which a man by mistake swallowed an ounce and a half of this liquid. The symptoms were somewhat like those produced by hydrochloric acid. He at first rallied, but died in about five weeks. The stomach was found partially inflamed, and thickened towards the intestinal end.

The solution of the perchloride is generally supposed to possess corrosive properties, and to leave the marks of its operation on the mouth, throat, and œsophagus. This, however, is not always the case. (See “Ann. d’Hyg.,” 1879, vol. 1, pp. 328 and 508.)

Comparatively small doses of this solution may seriously affect pregnant females, and among the criminal uses to which it has been put may be mentioned that of procuring abortion. At the Lincoln Lent Assizes, 1863 (*Reg. v. Rumble*), a druggist was convicted of having supplied this noxious compound to a woman with the intent to procure her miscar-

riage. The health of the woman was greatly injured by the administration of this liquid.

The above are the principal metallic irritants; but the compounds of *tin*, *silver*, *gold*, *bismuth*, and *chromium* have also an irritant action. Cases of poisoning by these substances are, however, very rare.

[*Subnitrate of bismuth. Pearl white.*—This substance is at present much used in medicine, in doses varying from five to thirty grains, in certain forms of dyspepsia, diarrhoea, etc. In some cases that have been reported, in which large doses proved highly irritating, and even fatal, there is strong reason for suspecting the presence of arsenic as an impurity in the medicine. The author states ("Prin. and Prac. of Med. Juris.," 1873), that the medicinal subnitrate generally contains arsenic. He found arsenic in a comparatively large proportion in samples obtained from three respectable druggists. Three specimens out of five contained it. The arsenic may easily be detected by dissolving the subnitrate in pure hydrochloric acid, slightly diluted, and using a Marsh's apparatus. This impurity may modify a legal opinion as to the presence of traces of arsenic in a body, where bismuth has previously been administered medicinally. A case of this nature (*State of Virginia v. Mrs. E. E. Lloyd*, 1872) has been reported, in which the defence ascribed the existence of a fraction of a grain of arsenic, alleged to have been found in the liver of the deceased, to the subnitrate of bismuth which had been administered before death; this bismuth was afterwards found to be contaminated with arsenic. The prisoner was acquitted.—R.]

VEGETABLE AND ANIMAL IRRITANTS.

CHAPTER XV.

VEGETABLE IRRITANTS.—ALOES.—SAVIN.—CROTON OIL.—COLCHICUM.—HELLEBORE.—ANIMAL IRRITANTS.—CANTHARIDES.—NOXIOUS ANIMAL FOOD.—FISH.—MUSSELS.—CHEESE.—SAUSAGES.—POISONED FLESH OF ANIMALS.—TRICHINIASIS.

General remarks.—The poisonous substances of an irritant nature which belong to the vegetable kingdom are very numerous as a class; but it will here be necessary to notice only those which have either caused death, or have given rise to accidental poisoning.

Aloes. Colocynth. Gamboge. Jalap. Scammony.—These different substances, which are used in small doses as medicines, are liable, when taken frequently, or in large quantities, to excite severe vomiting, purging, and other symptoms of irritation. Aloes and colocynth mixed are said to be the basis of a certain quack medicine sold under the name of Morison's Pills. These have proved fatal in many instances from the exhaustion produced by excessive purging, owing to the large quantity of these pills taken in frequently-repeated doses. In a recent case a dose of colocynth (three pennyworth) proved fatal to a woman at twenty-two. She was pregnant, and had taken the drug for procuring abortion. It operated as a violent irritant. ("Phar. Journ.," June 22, 1878, p. 1035.)

Hierapicra (Holy bitter) is a popular aloetic compound, and one death is recorded to have been produced by it in 1837–8. There is reason to believe that it is occasionally used for the purpose of procuring criminal abortion. A man was tried and convicted of this offence at the Aylesbury Lent Assizes, 1857 (*Reg. v. White*), and the noxious properties of this compound then became a subject of inquiry. The dose and the condition of the woman to whom it is administered will of course affect the answer to this question. At the trial above mentioned, it was properly considered to be a noxious substance within the meaning of the statute. The fact that, under the name of *Pulvis Aloes cum Canellâ*, it was formerly admitted into the British Pharmacopœia, cannot justify the mischievous uses to which it may be put. *Hierapicra* is a snuff-colored powder, of an intensely bitter taste. It consists of four parts, by weight, of aloes, and one part, by weight, of powdered canella bark. The proper medicinal dose was formerly fixed at from five to fifteen grains. Its injurious effects on pregnant females are chiefly due to the aloes. This specially affects the rectum, and by contiguity, under vio-

lent irritation or purging, may affect the uterus. From the taste and color which it imparts to liquids, it is not probable that it could be taken by a female unknowingly.

Savin (*Juniperus Sabina*).—This is a well-known plant, the leaves of which contain an irritant poison in the form of an acrid volatile oil of a remarkable odor. They exert an irritant action, both in the state of infusion and powder. They yield by distillation a light yellow oil, on

Fig. 19.
Tips of the leaves of *savin* magnified
30 diameters

which the irritant properties of the plant depend. The powder is sometimes used in medicine, in a dose of from five to twenty grains. Savin is not often taken as a poison for the specific purpose of destroying life; but this is occasionally an indirect result of its use as a popular means of procuring abortion. In this manner it appears to have proved fatal in one case in 1837-8. From the little that is known of its effects, it acts by producing violent pain in the abdomen, vomiting, and strangury. After death, the gullet, stomach, and intestines, with the kidneys, have been found either much inflamed or congested. It has no action

as an abortive, except, like other irritants, by causing a violent shock to the system, under which the uterus may expel its contents. Such a result can never be obtained without placing in jeopardy the life of a woman; and when abortion follows, she generally falls a victim. This poison may be identified by microscopic examination of portions of the leaves found in the stomach.

Croton oil.—This is an oil extracted from the seeds of the *Croton tiglium*. It is a powerful drastic purgative, producing, in a large dose, severe purging, collapse, and death.

M. Chevallier reports two cases of poisoning by this oil. In one, a druggist swallowed by mistake for cod-liver oil half an ounce of croton oil. He felt a burning sensation in the throat and stomach, soon followed by vomiting and copious purging, with symptoms of collapse. He did not recover until after a fortnight. In the other case, quoted from Devergie, a man, æt. 25, swallowed by mistake two drachms and a half of the oil. The most violent purging, with collapse took place, and the patient died in four hours. ("Ann. d'Hyg.," 1871, 1, 409.)

Meadow-saffron (*Colchicum*).—Meadow-saffron (*Colchicum autumnale*) contains a poisonous alkaloid—*colchicina*—the effects of which on animals are similar to those of *veratria*, the alkaloid existing in white hellebore. The most noxious parts of the plant are the bulbs (or roots) and seeds, but the leaves and flowers have also an irritant action.

Symptoms and appearances.—The symptoms in cases of poisoning by colchicum are generally well marked. There is burning pain in the throat and stomach, intense thirst, violent vomiting and purging leading rapidly to exhaustion, coldness and clamminess of the skin, excessive depression, and great weakness. The pulse is small, weak, and fluttering, and death appears to take place from complete exhaustion, without

convulsions or loss of consciousness. Among four cases presenting these symptoms, one person died on the second, one on the fifth, one on the eighth, and one on the fourteenth day. In another case of poisoning by wine of colchicum, the symptoms did not come on for an hour and a half; there was then copious vomiting of a yellow fluid, severe pain with great tenderness in the abdomen, tenesmus, and thirst. The patient died in forty-eight hours, without being convulsed or manifesting any sign of cerebral disturbance. The chief morbid appearance was a patch of redness in the mucous membrane of the stomach, near the cardiac orifice; the intestines were slightly inflamed. The head was not examined. ("Medical Gazette," vol. 10, p. 161; see also Casper, "Ger. Med.," p. 450.) In a case of poisoning by the medicinal administration of colchicum, communicated to me by Mr. Mann, of Bartholomew Close, three and a half drachms of the wine of colchicum were taken in divided doses, and caused death on the fourth day. There was no inflammation of the mucous membrane, but simply extravasation of blood into the mucous follicles. The mucous membrane has been found softened in two cases of poisoning by the tincture. In two other cases, in which an ounce and a half of the *tincture* was taken, and death ensued in forty-eight hours, no morbid appearances were found. (Casper, "Ger. Med.," 1857, p. 451, and see his "Vierteljahrschrift," 1860, vol. 1, p. 1.) See "Prin. and Prac. of Med. Jurisp.," 1873.

Colchicum has acquired an evil notoriety as a poison chiefly owing to the evidence given at a trial which took place at the Central Criminal Court, in September 1862 (*Reg. v. Catherine Wilson*). This woman, after having been tried and acquitted for an attempt to poison, with oil of vitriol, the wife of a man with whom she cohabited, was in the following September convicted of the murder of a *Mrs. Soames*, who had died suddenly while nursed by the prisoner six years previously. The body was exhumed, but no poison was found in the remains; yet the medical and other circumstances, as well as the conduct and correspondence of the prisoner, proved to the satisfaction of the court, that deceased had been destroyed by vegetable poison, most probably colchicum, with the noxious properties of which she was proved to have been well acquainted. From the facts which transpired in reference to this trial, it appeared that the deceased was one of four persons who had at different dates fallen victims to the acts of this woman. 1. *Peter Mawer*, a master mariner of Boston, died in October, 1854: the body was exhumed in 1862, but no poison was detected. 2. *Mrs. Jackson*, of Boston, who died in December, 1859: the body was exhumed in January, 1860, and no poison detected. 3. *Mrs. Atkinson*, of Kirkby Lonsdale, who died in October, 1860: the body was exhumed in May, 1865, and no poison detected. 4. The case of *Mrs. Soames*, above mentioned. All these persons died suddenly while in a state of health, under similar symptoms, and without any apparent natural cause to account for death. The symptoms as a whole were not reconcilable with any known disease; and they only appeared after the prisoner was proved to have administered, under some pretence or other, food or medicine, the bottle which she employed for this purpose being kept locked up, or in her own possession. The motive for the murder in each case was the acquisition

of money or property of which the prisoner came into possession—in Peter Mawer's case by a will made shortly before his death, and in Mrs. Atkinson's case by an act of robbery after her death. Two other attempts at murder which failed, led to the inference that colchicum was the substance which this woman employed, either in wine or brandy. In these four persons, the symptoms were as nearly as possible of the same character—burning pain in the throat and stomach, intense thirst, violent vomiting and purging, coldness and clamminess of the skin, excessive depression, and great weakness. The pulse was small and weak, and death appeared to take place from complete exhaustion, without convulsions or loss of consciousness. In most of the cases the poison was probably given in divided doses: in the last case, the symptoms appeared regularly every evening after the deceased had taken the tea prepared by the prisoner.

Colchicina.—The noxious properties of colchicum are owing to the presence of this alkaloid, which is remarkable for acquiring a reddish-violet color on the addition of strong nitric acid. It may be separated from liquids containing it by a process similar to that described for strychnia. (See STRYCHNIA.)

BLACK, WHITE, AND GREEN HELLEBORE.

Symptoms and appearances.—According to Wibmer, the roots of the black hellebore possess the greatest activity; but the leaves are also highly poisonous when used in the form of infusion. By long boiling the poisonous properties of the plant are diminished, probably owing to the loss of the volatile principle, which is an acrid oil. The roots and leaves have a local irritant action, producing violent vomiting and purging in small doses, with severe pain in the abdomen, followed by cold sweats, convulsions, insensibility, and death. The powdered root, in a dose of a few grains, acts like a drastic purgative. In a case reported by Morgagni, half a drachm of the aqueous extract killed a man, æt. 50, in eight hours. The symptoms were severe pain in the abdomen and violent vomiting. After death, the whole of the alimentary canal was found inflamed, but especially the large intestines. (Wibmer, *op. cit.*, HELLEBORS.) A case is quoted by the same writer, in which a tablespoonful of the finely-powdered root (taken by mistake for rhubarb) caused severe symptoms of irritant poisoning, which did not disappear for four hours. The man recovered on the fourth day. The experiments performed by Orfila on animals, show that this poison acts like a *local* irritant when applied to a wound. (*Op. cit.*, vol. 2, p. 369.) Hellebore is a favorite remedy for worms among quacks and rural doctresses. It is not, therefore, surprising that it should be occasionally administered in an overdose, and cause death. In December, 1862, Dr. Edwards met with a case in which a gentleman had swallowed experimentally one drachm of tincture of green hellebore (*veratrum viride*), equal to twelve grains of the powder. He was found soon afterwards in a collapsed state, features sunk, skin cold, and covered with a profuse clammy sweat, pulse scarcely perceptible. He complained of intense pain in the region of the stomach. There was no purging. These symptoms were relieved by treatment,

and the next morning the patient had recovered. ("Med. Times and Gazette," 1863, 1, 5.)

Veratria.—White hellebore owes its noxious properties to the alkaloid *veratria*, which is itself a powerful poison. The late Mr. Callaway communicated to me the following case. A physician prescribed medicinally for a lady one grain of *veratria* divided into fifty pills, and three were directed to be taken for a dose. Not long after the dose had been swallowed, the patient was found insensible, the surface cold, the pulse failing, and there was every symptom of approaching dissolution. She remained some hours in a doubtful condition, but ultimately recovered. Supposing the medicine to have been well mixed, and the pills equally divided, not more than one-sixteenth of a grain of *veratria* was here taken! The common *veratria* of the shops is sometimes given medicinally, in doses of one-sixth of a grain. Poisoning by *veratria* is a rare occurrence. I have not met with an instance in which this alkaloid has been administered with criminal intention. With the exception of the case above mentioned, there is no experience of its operation as a poison on man. Judging from its effects on animals, it would cause vomiting and convulsions, with insensibility.

Analysis.—In the state in which it is usually seen, it is a brownish-white powder, scarcely soluble in boiling water, but dissolved by alcohol, ether, and benzole. Acids readily dissolve it, forming salts which on evaporation do not yield crystals. The powder has a hot, acrid taste, and if any portion enters the nostrils it causes most violent sneezing, lasting for some time. Strong nitric acid gives to the powder a light red color, becoming ochreous after a time. Hydrochloric acid, strong or diluted, with the aid of heat produces a dingy red tint. The best test for its presence is diluted sulphuric acid, which by a gentle heat strikes a rich pink color, which is destroyed by a solution of chlorine, but not by chloride of tin. Strong sulphuric acid turns the powder yellow, but on heating the mixture the color deepens, and finally becomes a deep red; when the liquid is diluted it passes to a dingy yellow. *Veratria* undergoes no change when mixed with iodic acid, but it gives immediately with sulphomolybdic acid a deep greenish-yellow color, passing to a brown red.

Veratria differs from *colchicina* in its insolubility in water, as well as in the action of strong nitric and diluted sulphuric acids. It may be brought into solution in organic liquids by acetic acid and heat. The liquid is treated with potash and then shaken with two parts of benzole. The alkaloid if present is obtained by decanting and evaporating the benzolic solution. The tests may then be applied to it. It has not yet been detected in the tissues. A case occurred in September, 1865, in which death was attributed to the action of *veratria* criminally administered. The deceased, a woman, was advanced in pregnancy, and from the medical evidence she died from puerperal convulsions and Bright's disease of the kidney, with effusion of blood on the brain. It was said that *veratria* was detected in her body and in the urine, but there were no symptoms of poisoning by *veratria*, and there was no evidence of administration by any one. The chemical analysis was not published, or it might have appeared that too great a reliance had been placed upon

the tests employed. ("Med. Times and Gazette," Oct. 28, 1865, p. 472.) It was a case of death from natural causes, mistaken for poisoning.

Carbolic acid. Oil of tar.—This is a crystalline product of the fractional distillation of the oil of tar. In an impure state it has been long known as *creasote*. The crystals of carbonic acid melt at 95° , and the oily-looking liquid boils, and is entirely volatilized at 370° . It is sold commercially in a liquid form. Many instances of poisoning by this substance are now on record, the greater number having arisen from accident. It has such a powerful odor and taste that it could not be easily administered with homicidal intent. In a concentrated form it has a strong local action, and is a corrosive irritant; but it affects the brain like a narcotic poison. It acts on the unbroken skin, whitens it, hardens it, and destroys its sensibility for some time. It acts in a similar way on the mucous membrane, whitening, hardening, and corrugating it. In three instances it is reported to have destroyed life as the result of external application. ("Brit. Med. Journal," Oct. 8, 1870.) In one case the person died in two hours. The acid had been rubbed into the skin to cure the itch. ("Pharm. Journ.," March 22, 1873.) A girl under five years of age died from the absorption of this poison. An incision had been made in the arm in a surgical operation. The wound was covered with lint, soaked in carbolic acid, but without actual contact. In one hour the child was found insensible, and the face livid. She passed into a state of complete coma, and died half an hour later. ("Amer. Journ. Med. Sci.," July, 1873, p. 280; also, "Lancet," June 7, 1873.) These carbolic acid dressings have proved fatal in other instances. Dr. Küster met with five cases in which the acid was locally applied, and in four of them the patients died. ("Pharm. Journ.," June, 1878, p. 1032.) Dr. Lielewicz describes the cases of three children, between the ages of two and five years, on whom operations had been performed. The wounds had been washed with a solution of carbolic acid, and bandaged under the carbolic acid spray. The three patients became collapsed; they suffered from nausea and vomiting, as well as excessive perspiration. These were the results of the absorption of the acid. ("Brit. Med. Journ.," Dec. 1878, p. 966.) These cases should teach caution in the external use of carbolic acid.

Symptoms and appearances.—When the poison is swallowed in solution in a moderately concentrated state, the patient experiences a hot burning sensation extending from the mouth to the stomach. The symptoms come on in the act of swallowing; the lining membrane of the mouth is white and hardened. There is severe pain in the stomach, with vomiting of a frothy mucus. The skin is cold and clammy, the lips, eyelids, and ears are livid; the pulse 120 and intermittent; breathing difficult, with frothing at the mouth. There is insensibility, which comes on speedily, and passes into coma with stertorous breathing; there is a strong odor of carbolic acid in the breath and in the room; the pupils are contracted and insensible to light. The motions and urine, when passed, have been dark-colored. It operates with great rapidity. Death usually takes place within twelve hours, and sometimes within an hour. Among the *appearances* after death the following have been observed:

the interior of the mouth and jaws whitened, sometimes corroded; the gullet is also white, hard, and corrugated. The coats of the stomach have presented a horny consistency, without any signs of inflammation. The lungs have been found gorged with blood, and the bronchia filled with a brown-red thick mucus. In one case it caused death in less than an hour. ("Lancet," 1873, p. 302.) The effects of this poison depend more on the degree of concentration than the absolute quantity taken. A man by mistake swallowed at one draught a quantity of a five per cent. solution of carbolic acid, equivalent to one hundred and forty grains. He soon became pale, with a clammy sweat over the surface; the limbs were cold; the pupils semi-dilated; the jaws closed; the abdomen distended; the pulse small and hot, capable of being counted, with general twitching of the muscles. The stomach pump was immediately used with benefit, consciousness returned, and the patient recovered in a few hours. The urine which was passed had a dark green color. ("Brit. Med. Journ.," Dec. 28, 1878, p. 966.) One of the most remarkable points connected with the action of this poison is the rapidity with which insensibility comes on. A man, æt. 27, was brought to Guy's Hospital in October, 1879. He had shortly before swallowed two and a half ounces of the common black carbolic acid. In five minutes he became insensible. When brought to the hospital he was drowsy, but easily roused. But little urine was passed; it contained traces of carbolic acid. In three days the man recovered. ("Guy's Hosp. Gazette," February, 1879.)

Analysis.—The strong and peculiar odor perceptible in the breath, in the vomited matters, and in the room, generally suffice to indicate the nature of the poison. Carbolic acid is partially dissolved by water, and is very soluble in alcohol, ether, or solution of potash. It has no acid reaction; it gives a greasy stain to paper, and burns with a smoky flame. There is no test for its presence so delicate as the odor; but a solution of a persalt of iron, if not too acid, gives with it a dark purple color like ink. It may be separated from the contents of the stomach by shaking them with ether, decanting the ethereal liquid, and allowing the ether to evaporate. Oily-looking globules of carbolic acid are thus obtained. Bromine water gives a dense white precipitate, with a small quantity of carbolic acid, when dissolved in water. Dr. Davey has recently recommended molybdic acid as a delicate test. ("Pharm. Journ.," June, 1878, p. 1021.)

YELLOW JESSAMINE. GELSEMIUM SEMPERVIRENS.

An alcohol extract of the root of this plant has been used in the United States for medicinal purposes. It has acted as a poison and destroyed life, but its exact place as a poison cannot yet be satisfactorily assigned. From a case reported by Dr. Walmsley (see "Americal Journal of Pharmacy," Jan. 1870) it appears to belong rather to the irritant than the narcotic class of substances.

A young healthy married woman took by mistake three teaspoonfuls of the fluid extract of gelsemium—a concentrated tincture of the root containing 480 grains to the ounce. In two hours after taking the extract,

she complained of pain in the stomach, nausea and dimness of vision. These *symptoms* were followed by great restlessness, ineffectual efforts to vomit, and general perspiration. In four hours the pulse was feeble, irregular, and intermittent. There was great prostration, with irregular and slow breathing. The skin was dry, the limbs were cold, the pupils dilated and insensible to light; the eyes were fixed, and there was inability to raise the eyelids. The vital powers rapidly gave way, and without convulsion, death occurred in seven hours and a half after the poison had been taken. On inspection after death, nothing characteristic was discovered.

Analysis.—Dr. Wormley discovered that the extract contained an alkaloid (*gelseminine*) separable by ether or chloroform, and an organic acid (*gelseminic acid*). The latter he was able to obtain crystallized in various forms by solution and sublimation. He found that if a small quantity of this acid, or its salts, in a solid state was treated with a drop of concentrated nitric acid, it became yellow or reddish, according to the quantity. When an excess of ammonia was added, it acquired a blood-red color. The $\frac{1}{100}$ th part of a grain was sufficient for this reaction. The solution in potash is fluorescent, presenting a deep blue coloration on the surface. Gelseminic acid was thus detected in the contents of the stomach some months after death.

The alkaloid *gelseminine* is, according to Dr. Wormley, a potent poison. One-eighth of a grain by hypodermic injection killed a rabbit in one hour and a half. In fifteen minutes there were symptoms of great distress, and the animal was restless. In forty minutes there was great prostration, inability to move, respiration gasping, and the pupils were dilated, but there were no convulsions. From his experiments, Dr. Wormley infers that the quantity which proved fatal to the woman in the above-mentioned case, could not have exceeded the sixth part of a grain.

ANIMAL IRRITANTS.

CANTHARIDES (SPANISH FLIES). *Symptoms*.—When cantharides are taken in *powder*, in the dose of one or two drachms, they give rise to the following symptoms: A burning sensation in the throat, great difficulty of swallowing, violent pain in the abdomen, with nausea and vomiting of a bloody mucus; there is also great thirst, with dryness of the fauces. As the case proceeds, a heavy dull pain is commonly experienced in the loins, and there is an incessant desire to void urine, but only a small quantity of blood or bloody urine is passed at each effort. The abdominal pain becomes of a violent griping kind. Purging supervenes, but this is not always observed; the matters discharged from the bowels are mixed with blood and mucus, and there is often tenesmus (straining). In these, as well as in vomited liquids, shining green or copper-colored particles may be commonly seen on examination, whereby the nature of the poison taken, if it has been taken in powder, will be at once indicated. After a time, there is priapism, and the genital organs are swollen and inflamed both in the male and female. When the case proves fatal, death is usually preceded by faintness, giddiness, and convulsions. The *tincture* of cantharides produces similar symptoms:—they are,

however, more speedily induced, and the burning sensation in the stomach and constriction of the throat are more strongly marked: this symptom is often so severe as to render it impossible for the person to swallow; and the act of swallowing gives rise to excruciating pain in the throat and abdomen. For the symptoms and appearances in a case in which three ounces of the tincture proved fatal, see "Brit. Med. Jour.," Feb. 1876, p. 191.

Cantharides are sometimes secretly administered for the purpose of exciting erotic feelings. In these cases the quantity given may be so large as to develop the poisonous action of the drug. Dr. Brandao, a Brazilian physician, has reported a case of this kind which occurred in his practice in January, 1877. ("Revista Medici de Rio de Janeiro," 1878). A courtesan put some cantharides into a glass of wine, and handed it to a young man, æt. 23. He observed that it was rather turbid, but drank it without suspicion. In about an hour he was seized with a strong desire to urinate, but in spite of all his efforts he could pass only a few drops of scalding urine, attended with severe pain throughout the length of the urethra. There was priapism, with great pain in the lumbar region and nausea with intense thirst. The patient was restless, the eyes were injected and lustrous, the pupils dilated, and the countenance animated. The pulse was small and frequent. The desire to micturate was incessant, but only a small quantity of urine could be discharged, and this was thick and bloody. The abdomen was retracted and sensitive to pressure, and there was pain in the region of the kidneys, extending down to the perineum. The catheter brought away a small quantity of thick bloody urine containing albumen in marked proportions. Under treatment the man recovered in three days. The urine was then passed naturally, and it contained no albumen.

Appearances.—In one well-marked case, the whole of the alimentary canal, from the mouth downwards, was in a state of inflammation. The mouth and tongue seemed to be deprived of their mucous membrane. The ureters, kidneys, and internal organs of generation were also inflamed. In another instance, in which an ounce of the tincture was swallowed, and death did not occur for fourteen days, the mucous membrane of the stomach was not inflamed; but it was pulpy, and easily detached. The kidneys were, however, inflamed. The brain has been found congested, and ulceration of the bladder is said to have been met with. There are few fatal cases reported in which the quantity taken and the appearances have been accurately noted; indeed, the greater number of those who have taken this poison have recovered.

The quantity required to produce serious symptoms, or to destroy life, has been a frequent subject of medico-legal inquiry. The medicinal dose of the tincture is from ten minims gradually increased to one fluid-drachm,—of the powder from *one to two grains*. (Pereira, "Mat. Med." part 2, vol. 2, p. 754.) Even in doses of less than two grains cantharides have produced irritation of the bladder, stringency and other well-marked symptoms. Some persons appear to be peculiarly susceptible of the action of this drug, so that when used medicinally it has been found necessary to withdraw it. Doses above those mentioned, whether of the powder or the tincture, are likely to be injurious, and to give rise to

symptoms of poisoning. The *smallest quantity* of the powder which has been known to destroy life, was in the case of a young woman, quoted by Orfila; the quantity taken was estimated at *twenty-four grains*, in two doses. She died in four days; but as abortion preceded death, this may have been concerned in accelerating that event.

An *ounce* of the tincture taken by a boy, æt. 17, caused death in fourteen days. This, I believe, is the smallest dose of the tincture which is recorded to have proved fatal. It must not be inferred from this statement that a smaller quantity of the powder or tincture will not destroy life. The actual dose of either required to prove fatal is unknown. Many more observations are required to determine this point with accuracy. In *Reg. v. Hennah* (Cornwall Lent Assizes, 1877) it was wrongly inferred that it would require at least twenty-four grains of the powder to destroy life. There is nothing to prevent half of this quantity from proving fatal: this is purely a matter of experience. It is at present impossible to assign any definite quantity as a minimum fatal dose.

Chemical analysis.—For the detection of the powder, M. Poumet recommends that the sediment obtained from the suspected liquids, should be mixed with alcohol spread on sheets of glass, and allowed to evaporate spontaneously to dryness. The shining scales of the powdered elytra will then be seen, on examining the glass by reflected light, either on one or both surfaces. ("Ann. d'Hyg.," Oct. 1842.) As the powder

is insoluble in water, some portion of it may generally be obtained by washing and decantation. The sediment may then be examined on a glass-slide with the microscope. If no portion of the powdered beetles can be procured, the suspected liquids or solids should be brought to dryness, and the dry residue digested in successive quantities of ether until exhausted. This will dissolve the cantharidine, which forms, according to some authorities, only the 1-250th part of the elytra of the beetle. Other analysts have found the proportion to be from 0.3 to 0.72 per cent. ("Pharm. Jour.," March, 1880, p. 729.) The ethereal solutions are evaporated to an extract, and some of this extract, spread on oil-

Fig. 20.
Crystals of cantharidine from a solution in chloroform, magnified 20 diameters

silk, may be applied to a thin portion of the skin of the arm or to the lips. The production of a blister, with serum, under these circumstances, is considered to indicate the presence of cantharidine. By this method Barruel discovered cantharides in chocolate. ("Ann. d'Hyg." 1835, 1, p. 455.) Chloroform is even a more powerful solvent of cantharidine than ether, and may be used in preference. (Fig. 20.) As the extract contains frequently a green oil and fat, which prevent cantharidine from crystallizing, it has been recommended to employ sulphide of carbon, in order to separate these impurities, the cantharidine not being soluble in the sulphide, while the fat is removed. (See on this subject "Pharm. Jour.," March, 1880, p. 729.)

NOXIOUS ANIMAL FOOD.

Certain kinds of animal food are found to produce, occasionally, symptoms resembling those of irritant poisoning. In some instances this poisonous effect appears to be due to idiosyncrasy; for only one person out of several partaking of the food, may be affected. These cases are of importance to the medical jurist, since they may give rise to unfounded charges of criminal poisoning. In the absence of any demonstrable poison, we must test the question of idiosyncrasy by observing whether more than one person is affected, and whether the same kind of food, given to animals, produces symptoms of poisoning. If with this latter condition several persons are affected simultaneously with similar symptoms, we cannot refer the effects to idiosyncrasy; they are most probably due to the presence of an animal poison. Among the articles of food which have caused symptoms of irritant poisoning, may be mentioned cheese, certain shell-fish (mussels), bacon, sausages, diseased pork, and animal flesh in a diseased or putrescent state.

Tinned meat from America has occasionally given rise to symptoms of irritant poisoning. In one instance reported in the "British Medical Journal" (Nov. 1, 1879, p. 707), twenty-one persons suffered from eating corned ox hearts from a six pound tin. The symptoms were vomiting and purging, with collapse, cramps in the legs, vomiting of blood, and severe pain in the stomach. Some of the patients suffered from drowsiness; all recovered. No poison could be detected by chemical analysis.

The flesh of the most healthy animal is rendered unfit for food when it is putrescent. It is not merely unwholesome, but highly irritant, causing rapidly vomiting, purging, pain, and other symptoms of a severe kind. Fortunately these symptoms lead at once to the expulsion of the noxious food from the body, and the person then recovers: the young, the old, and the infirm may, however, be so prostrated by excessive vomiting and purging, that they may sink from exhaustion. Animal matter in a state of partial decay, or in the transition stage of putrefaction, must also be regarded as of a poisonous nature. Much of the cheap butcher's meat sold to the poor is in a state of decay, and is quite unfit for human food. In January, 1851, the family of a surgeon near London were all affected with symptoms resembling irritant poisoning, after having partaken of a hare which had been stewed in a clean earthen vessel. The surgeon informed me that on the second day, his wife was seized with vomiting and purging, giddiness, heat in the throat, and general numbness, with inflamed eyes. Other members of the family vomited, and in the course of a few days the symptoms disappeared. I examined the vomited matter, and found it to consist of portions of the hare partially digested, but in a state of putrefaction, so that there was abundant evidence of sulphuretted hydrogen in the liquid. There was no mineral poison of any kind, although the symptoms, it will be observed, were rather like those occasioned by arsenic. It had been remarked by the family, that a silver spoon, which had been used in serving out this unwholesome food, was turned of a brown color, no doubt from the chemical action of sulphuretted hydrogen; and this may be taken as a good domestic test of the putrefied condition of such food. Nature generally

applies an appropriate remedy, in the fact that the food itself produces copious vomiting and purging. (See "Brit. Med. Journ.," Sept. 1877.) An accident occurred at St. Petersburg in which a number of persons suffered from symptoms of poisoning as a result of eating codfish which was in an unwholesome state. It had been kept too long, and had undergone decomposition. Four men had for supper a portion of the fish in a dried and salted state. In two hours they were seized with severe colic, vomiting and purging, and spasms in the legs. They became collapsed and lost consciousness. There was somnolency, and the pupils were dilated. These symptoms continued at intervals. One man died in twenty-four hours. Blood was found effused in the stomach, and there was a general redness of the mucous membranes of the intestines. It is stated that as many as one hundred and three persons were affected in a similar way. ("Brit. Med. Journ." 1879, p. 21.)

Cases of this kind must be distinguished from those in which *poisoned food* is sold to the public. The game may be quite free from putrefaction, but noxious from the poisoned grain which may have caused death. It is a very common practice to steep grain in a solution of arsenic, previous to sowing, and pheasants, partridges, and other birds may be accidentally destroyed by eating the grain. In some instances grouse and other game are maliciously destroyed by the laying of corn, saturated with arsenic or other poisons, in the localities where the birds abound. There is no law to prevent the sale of poisoned game by poulterers, and there is no precaution which can be taken by the purchasers, except by observing whether the birds have, or have not been shot. [Frequent cases of poisoning from eating the flesh of the pheasant (*Tetrao umbellus*) have occurred in the United States. This bird, during the winter season, has sometimes caused dangerous symptoms in persons who have eaten it. These have generally been attributed to the fact of the bird having fed upon the leaves and buds of the laurel (*kalmia*), and many facts have here been adduced which are considered as corroborating this opinion, the most striking of which is the occurrence of the leaves of the plant in the crops of the birds. Notwithstanding this almost universal belief, Dr. Griffith, in the former edition of this work, is not satisfied with this explanation, but is inclined to attribute it to some change in the flesh analogous to that noticed above, as taking place in other meats, since the symptoms are almost identical, and these cases are rare, whilst nearly all these birds feed on the laurel, when the ground is covered with snow and other food cannot be readily obtained.—H.] (See on this subject, "ON POISONS," 3d ed. p. 532; also "Med. Gaz." vol. 42, p. 1036; and for the effects produced by pork containing the *trichina spiralis* and other parasites, the reader is referred to the section on trichinosis in "POISONS," p. 539.)

Trichiniasis.—The fatal malady arising from the introduction of the *trichina spiralis* into the human body, has recently attracted much attention in France and Germany; and among others, Dr. Keller, of Darmstadt, has published some important facts illustrating the symptoms produced, and the mode in which this parasite causes death. Dr. Keller considers that it is a question well worthy of the attention of medical jurists, whether many cases of death from suspected irritant poisoning, in which

no poisonous matter could be detected in the body, may not have been really due to trichina disease.

The trichina (from *τρίχ*, a hair) *spiralis*, a flesh-worm, is found chiefly in the course of the fibres of all the striped muscles of the trunk and limbs, most frequently on those of the front of the chest, neck, and abdomen. It has also been found on the muscular fibres of the heart and esophagus. The parasites appear in the form of very small ovoid bodies, or capsules, perceptible to the eye as white specks, in the midst of muscular fibres, but only distinctly seen by the aid of a magnifying glass. The trichina, or worm, is coiled up in the centre of each oval capsule, the greater diameter of which is always parallel to the muscular fibre with which it is closely incorporated. Fig. 22 is taken from a preparation in the Museum of Guy's Hospital; it represents a portion of the abdominal muscles of a man, covered with trichinæ *in situ*, and as nearly as possible of the natural size. Fig. 21 represents three of the capsules, *b b b*, magnified, with the trichina coiled up in the centre of one of them.

Fig. 21.

Magnified view of trichina spiralis in its capsule.
a. The worm coiled.
b. The capsules.

Fig. 22.

Trichina spiralis in the abdominal muscles of a man, natural size of the capsules containing the worm.

These parasites are frequently so numerous as to give to the red flesh a white speckled appearance. According to Dr. Keller, as many as 300,000 have been counted in half a pound of raw meat; and Dr. Pietra Santa affirm that one gramme (about sixteen grains) of diseased meat may contain 6000 trichinæ, each having from sixty to eighty embryos. ("Ann. d'Hyg.," 1864, vol. 1, p. 317.)

The actual size of the capsule has been variously stated. From an examination of two sets of specimens in the muscles of the throat and abdomen, I estimated the long diameter to be the $\frac{1}{16}$ th of an inch, and the short diameter $\frac{1}{16}$ th. The worm itself is said to be $\frac{1}{16}$ th of an inch in length. The capsules are remarkably uniform in size. They are built up at the expense of the muscular structure by which they are surrounded.

The history of this animal has been given by numerous pathologists. ("Hodgkin's Lectures on Morbid Anatomy," 1836, vol. 1, p. 211.) A full description of its anatomy and habits by Dr. Bristowe and Mr. Rainey will be found in the "Transactions of the Pathological Society," for 1853-54, p. 274. More recent accounts of its influence on health by Dr. Pietra Santa, have been published in the "Ann. d'Hyg.," 1864,

vol. 1, p. 365 ("La Trichina spiralis"), and by Drs. Schultze and Lucke in Casper's "Vierteljahrsschrift für gerichtliche Medicin," 1861, No. 1, p. 103, and No. 2, p. 269. Dr. Lucke's paper is of especial interest, as its title, "Die Trichinen vor dem Forum," implies, since it points to the medico-legal bearings of the subject, and the possible danger of confounding the ravages of this parasite with the obscure effects produced in certain forms of chronic irritant poisoning.

From these researches it is now clearly established that the trichina is a viviparous parasite, which passes the greater part of its existence in the chrysalis state in the muscular system, until, by the consumption of this muscle as food, it finds in the stomach and intestines of another warm-blooded animal a favorable medium for its full development into an intestinal worm. According to Virchow and Zenker, the trichina not only frequently presents itself in the human organism, but this organism is most favorable to its development. The period of incubation of the chrysalis in the stomach and bowels of man, or of warm-blooded animals, is from six to eight days; and during this time it there thrives and propagates to an almost incredible extent. Dr. Keller states that in three or four days the females produce 100 or more young ones, which begin on the sixth day to leave the parent animal; and he estimates that in a few days after the ingestion of half a pound of meat, the stomach and intestinal canal of a person may contain thirty millions of these minute worms. M. Herbst found the muscles of two dogs which had been fed upon parts of a badger containing worms, to be loaded with these parasites. When once introduced into the stomach and intestines, the worms leave their capsules, become free, and produce young, which migrate through the walls of the intestines into the muscles; there they become encysted, and are ultimately found appropriating and destroying the muscular substance to a greater or less extent. The sudden liberation of a large number of these worms causes irritation and inflammation in the bowels, attended by peculiar symptoms resembling in some respects those of poisoning.

It is worthy of note that trichinae are more frequently found in pork and articles of food derived from it, than in any other kind of meat. Measly pork appears to be sometimes of a trichinous character. Further, the vitality of the parasites is not destroyed unless the meat, or other substances in which they are located, has been subjected to a temperature equal to that of boiling water for a sufficient time to insure that every particle has been exposed to this degree of heat. Salting and smoking, or partial cooking, is not sufficient to destroy the worms in all parts of the food, and they have even been found living in putrefied meat. This may serve to account in some cases for the serious symptoms which have followed the use of pork as food, also of bacon, sausages, and German sausages, which are generally made of raw ham.

The symptoms produced by the use of such food are, in the first stage, those of intestinal irritation, loss of appetite, sickness, pain, general weakness of the limbs, with diarrhoea, swelling of the eyelids and of the joints, profuse clammy perspiration, and a wasting fever, sometimes of a typhoid character. Death is either the result of paralysis (from destruction of the muscular fibres), or of peritonitis and irritative fever.

During the perforation of the coats of the intestines by these worms, the mucous membrane becomes irritated and inflamed; pus is formed on its surface, and bloody evacuations are sometimes passed. No case is known in which trichiniasis, after having once declared itself, was arrested by medical treatment.

The noxious effects of this food on human beings are well illustrated by a series of cases which occurred at Hettstädt, in the Hartz Mountains, in 1863. ("British Med. Journal," Jan. 16, 1864, p. 75.) One hundred and three persons partook of smoked sausages made from a pig affected, as it turned out, with trichinous disease. The sausages were fried, and served for dinner in the usual way. On the following day, several persons who had partaken of this food were attacked with severe pain in the bowels, purging, loss of appetite, great prostration of strength, and fever. The number of persons attacked rapidly increased, symptoms of peritonitis and pneumonia manifested themselves, and these were followed by paralysis of the intercostal muscles, and of the muscles in front of the neck. Eighty-three persons died from the effects of this noxious food, and the remainder were seriously injured in health. The remnants of sausage and of pork not eaten at this festival were examined, and were found to be literally swarming with encysted trichinæ. (See Casper's "Vierteljahrschrift," April, 1864, p. 286.) The writer in the above journal affirms that this parasitic disease does not attack sheep, oxen, or horses, and that beef is the safest of all descriptions of food, as no parasites have ever been discovered in it. They have not been found in the blood of animals whose muscles are liable to their attacks.

[The "Chicago Medical Journal" for August, 1866, contains an article contributed by Dr. E. M. Smith, of Linn County, Iowa, in which is reported a case of poisoning of a family of nine persons by eating trichinous pork. They were all taken sick about the same time in the early part of May, 1866, after having eaten portions of raw smoked ham some five or ten days before. Dr. Smith was not called in until they had been sick for a week or more; at which time "the prominent symptoms observable were: more or less diarrhœa; tenderness of the abdomen; tongue thickly coated, contracted, and red about the edges; œdema of the face in several of the cases; considerable pneumonic irritation in some; fever of a typhoid character; pulse ranging from 100 to 120 per minute; great thirst, and profuse sweating; complaint of soreness and stiffness of the muscles, a difficulty of extending the limbs, wakefulness at night, and excessive exhaustion. Each case exhibited more or less of the symptoms enumerated, the difference being merely in intensity. Five of the patients died (the first death occurring on the 30th May, and the last one the 17th June), upon two of whom *post-mortem* examinations were made. "Upon placing minute particles of these muscles" (the rectus femoris and biceps) "under the glass, the parasites were seen in great numbers—the veritable *trichinæ spiralis*. Many of these were very active, and were readily seen to coil and uncoil, and to exhibit an activity commensurate with the terrible work they had done. I counted twenty-six trichinæ in one field of the glass; and upon placing a piece of the rectus femoris, $\frac{1}{2}$ of an inch in diameter, under the object glass, 104 trichinæ were counted, which would give nearly 200,000 parasites to

the cubic inch." "No lesions of a pathological character were found, the appearance of the viscera being nearly or quite normal. Portions of the muscles from different parts of the body were removed for microscopic investigation; also of the liver, spleen, and lungs. The voluntary muscles were swarming with trichinæ; some were found in the lungs and spleen, but none in the heart and liver." The patients who recovered had eaten but a very small quantity of the raw meat. The observations of Dr. Smith showed that it was probable that the "activity of the parasite begins to subside in from forty to fifty days from the first indications of the malady."—P.]

Although little has been heard of trichinous disease in England, it appears to have been prevalent in Germany. In February, 1864, a whole family was poisoned at New York, and one member died from eating part of a ham, which, on microscopic examination, was found to be full of the *trichina spiralis*. Death was referred by the medical attendant to this cause.

As a means of distinction from irritant poisoning may be pointed out the long time which commonly elapses between the taking of the food and the commencement of the symptoms. The pain, vomiting and purging are comparatively slight; the pain is in the bowels rather than in the stomach, and peritonitis, pneumonia, and fever are not commonly results of the action of irritant poisons, while they appear to be constant symptoms in trichiniasis. The absence of ordinary poison in the food, in the urine, and the evacuations, at any stage, may also be taken as conclusive evidence against irritant poisoning in its usual form.

Fig. 23.

Fig. 24.

Trichina spiralis encased in pork. This engraving represents the completely encysted worm in horizontal section showing six apparent stumps, which proves that the worm lies in three convolutions when it has attained its full size.

In suspected cases, a new method of research must be added to those already in use. If any of the food can be obtained, this must be examined for the parasite by the aid of the microscope. If the case proves fatal, the voluntary muscles of the deceased must undergo a similar examination.

In the "Canada Medical Journal" for 1870-1, Dr. J. B. Edwards has published a full account of the best methods of detecting trichinæ in the flesh of man and animals. He has furnished me with some excellent photographs of the worms *in situ* in human and animal muscle, of which engravings are annexed.

In some cases which occurred at Montreal, the cause of the symptoms was at first obscure, but Dr. Edwards not only found trichinæ in a slice of ham which had been eaten, but in the muscles of two of the patients who recovered. He removed about five grains of muscular tissue from the gastrocnemius muscle, and twelve grains of the tibialis posticus. In both of these portions of muscle about forty worms were found. (Op. cit. p. 517; see also Dr. Thudichum's "Report to Privy Council for 1854-5.")

NEUROTIC POISONS.

(NARCOTIC, OR CEREBRAL POISONS.)

CHAPTER XVI.

OPIUM.—SYMPTOMS.—APPEARANCES.—ITS ACTION ON INFANTS.—POISONING WITH OPIATE COMPOUNDS.—MORPHIA AND ITS SALTS.—PROCESS FOR DETECTING OPIUM IN ORGANIC MIXTURES.

OPIUM.

Symptoms.—The symptoms which manifest themselves when a large dose of opium, or its tincture, has been taken, are in general of a uniform character. They are: giddiness, drowsiness, a strong tendency to sleep, stupor, succeeded by perfect insensibility, the person lying motionless, with the eyes closed as if in a sound sleep. In this state he may be easily roused by a loud noise, and made to answer a question; but he speedily relapses into stupor. In a later stage, when coma has supervened with stertorous breathing, it will be difficult, if not impossible, to rouse him. The pulse is at first small, quick, and irregular, the respiration hurried, and the skin warm and bathed in perspiration, sometimes livid; but when the person becomes comatose, the breathing is slow and stertorous; the pulse slow and full. The skin is occasionally cold and pallid. The pupils, in the early stage, are contracted; in the later stage, and when progressing to a fatal termination, they may be found dilated. In a case referred to me in 1846, one pupil was contracted and the other dilated. In infants and children they are generally much contracted. They are commonly insensible to light. The expression of the countenance is placid, pale, and ghastly; the eyes are heavy, and the lips are livid. Sometimes there is vomiting, or even purging; and if vomiting takes place freely before stupor sets in, there is great hope of recovery. This symptom is chiefly observed when a large dose of opium has been taken; and it may then be, perhaps, ascribed to the mechanical effect of the poison on the stomach. The peculiar odor of opium is occasionally perceptible in the breath. Nausea and vomiting, with headache, loss of appetite, and lassitude, often follow on recovery. In cases likely to prove fatal, the muscles of the limbs feel flabby and relaxed, the lower jaw drops, the pulse is feeble and imperceptible, the sphincters are in a state of relaxation, the pupils are unaffected by light, the temperature of the body is low, there is a loud mucous rattle in breathing, and convulsions are sometimes observed before death, but more commonly in children than in adults. One of the marked effects of this poison is to suspend all the secretions except

that of the skin. Even during the lethargic state, the skin, although cold, is often copiously bathed in perspiration. It is a question yet to be determined, whether this may not be a medium by which the poison is principally eliminated. The contracted state of the pupils has been hitherto considered to furnish a valuable distinctive sign of poisoning with opium or the salts of morphia. In relying upon it, it is necessary to bear in mind the fact pointed out by Dr. Wilks, that, in apoplexy which is seated in the pons Varolii, the pupils are also contracted. He describes two cases of this form of apoplexy which were mistaken for poisoning by opium in consequence of this condition of the pupils. ("Med. Times and Gazette," 1863, 1, p. 214.) The symptoms above described usually commence in from *half an hour* to *an hour* after the poison has been swallowed. Sometimes they come on in a few minutes, especially in children; and at other times their appearance is protracted for a long period.

It has been frequently observed, on these occasions, that a person has recovered from the first symptoms, and has then had a relapse, and died. There is some medico-legal interest connected with this state, which has been called secondary asphyxia from opium, although there appears to be no good reason for giving to it this name.

Appearances.—In a case which proved fatal in fifteen hours, the vessels of the head were found unusually congested throughout. On the surface of the forepart of the left hemisphere there was an ecchymosis, apparently produced by the effusion of a few drops of blood. There were numerous bloody points on the cut surface of the brain; there was no serum collected in the ventricles. The stomach was quite healthy. Fluidity of the blood is mentioned as a common appearance in cases of poisoning by opium. There is also engorgement of the lungs; most frequently observed, according to Sir R. Christison, in those cases which have been preceded by convulsions. (Op. cit., p. 732.) Among the external appearances there is often great lividity of the skin. Extravasation of blood on the brain is rarely seen; serous effusions in the ventricles, or between the membranes, are sometimes met with. The stomach is so seldom found otherwise than in a healthy state, that the inflammatory redness said to have been occasionally seen, may have been due to accidental causes. From this account of the appearances in the dead body, it will be perceived that there is nothing but a fulness of the vessels of the brain which can be looked upon as specially indicative of poisoning with opium, and even this is not always present.

Absorption and Hypodermic injection.—Morphia and its salts rapidly destroy life by absorption when applied to a wounded or ulcerated surface. A woman thus lost her life in 1867, by reason of an ignorant druggist applying *thirty grains* of morphia to an ulcerated breast. Of late years a new form of poisoning has sprung up, in what is known as hypodermic injection. Patients and their friends have thus caused fatal accidents by ignorantly injecting into the cellular membrane too large a quantity of morphia, or by repeating the injection of a small quantity at too frequent intervals. In certain cases death is the result of rapid absorption. In October, 1879, a lady died with tetanic symptoms, caused, as it was supposed, by the hypodermic injection of a large dose of mor-

phia. A medical man who was called in found her suffering from symptoms of tetanus. She had been subject to attacks of neuralgia, and to relieve them she had been for years in the habit of injecting morphia under the skin. She admitted that on that morning she had used twelve grains of morphia as an injection, although the ordinary dose was from one-eighth to one-quarter of a grain. A dose of two or three grains thus injected has proved fatal. The medical man in this case attributed the tetanus not to the morphia, but to some wound of a nerve in inserting the fine point of the syringe. A post-mortem examination showed that the organs of the body were in a healthy condition, but the entire front of the deceased's body was covered with the scars of innumerable punctured wounds, produced by the needle, as if, in fact, she had been tattooed. Other medical men thought that strychnia might in this case have been injected by mistake for morphia, but as the deceased lived nine days after the injection this is highly improbable. The very large doses of morphia used may have caused the tetanic symptoms. At any rate this appears more probable than that the last puncture with the needle should have caused traumatic tetanus, as she had undergone the operation on numerous occasions previously without any tetanic symptoms showing themselves.

The medicinal *dose* of opium, in *extract* or *powder*, for a healthy adult, varies from half a grain to two grains. Five grains would be a very full dose. The medicinal dose of the *tincture* (laudanum) is from ten minims to one drachm, as an average, from thirty to forty minims. Persons have taken very large doses of the tincture, and recovered from the effects. A woman, æt. 38, is said to have recovered after swallowing eight ounces. ("Lancet," 1873, 1, p. 468.) The *smallest dose of solid opium* which has been known to prove fatal to an adult was in a case reported by Dr. Sharkey, of Jersey. A man, æt. 32, died very speedily in a convulsive fit, after having taken two pills, each containing about one grain and a quarter of extract of opium. This quantity is equivalent to *four grains* of crude opium. ("Med. Gaz.," vol. 37, p. 236.) The *smallest fatal dose of the tincture* in an adult which I have found recorded is *two drachms*. ("Ed. Med. and Surg. Journ.," July, 1840.)

In connection with this subject it is important for a medical jurist to bear in mind that *infants* and young persons are liable to be killed by very small doses of opium; they appear to be peculiarly susceptible of the effects of this poison. The syrup of poppies, paregoric elixir, Godfrey's cordial, Dalby's carminative, and a variety of *soothing syrups* owe their narcotic effects to the presence of opium. The symptoms and appearances which they produce, when taken in a large dose, are similar to those caused by opium or its tincture. One-sixtieth part of a grain of opium has thus destroyed the life of an infant. ("Brit. Med. Journ.," Oct. 30, 1875, p. 570.) Two children, twins of six weeks, died recently from the effects of a teaspoonful of Godfrey's cordial given to each. The medical man who saw the children calculated that this dose of the cordial contained three-tenths of a grain of opium. ("Pharm. Journ.," 1880, March 13, p. 746.) Mrs. Winslow's "Soothing Syrup," called also "Quietness," appears to be a compound resembling syrup of poppies. Its effects are those of a narcotic. Two doses of this caused

the death of a child aged fifteen months, with the usual symptoms of narcotic poisoning. ("Pharm. Journ.," June, 1872, 618.) An analysis of this syrup showed that one ounce of it contained nearly one grain of morphia with other opium alkaloids. ("Pharm. Journ.," June, 1872, 975.) It is not surprising that it should prove fatal to infants in small doses.

It has been remarked that most cases of poisoning by opium prove fatal in from about six to twelve hours. They who recover from the stupor, and survive longer than this period, generally do well; but there may be a partial recovery, or a remission of the symptoms, and afterwards a fatal relapse. The symptoms, however, generally progress steadily to a fatal termination, or the stupor suddenly disappears, vomiting ensues, and the person recovers. Several instances are recorded of this poison having destroyed life in from seven to nine hours. One has occurred within my knowledge in which an adult died in five hours after taking the drug prescribed for him by a quack. Sir R. Christison met with a case which could not have lasted above five, and another is mentioned by him which only lasted three hours. Mr. Barwis, of Melton, communicated to me the case of an adult (November, 1863) which proved fatal in three hours and a half. This drug in all its forms is especially fatal to infants. They die rapidly from very small doses.

Morphia and its Salts.—Morphia is the poisonous alkaloid of opium, of which it forms from five to ten per cent. The two principal salts of this alkaloid are the *hydrochlorate* and the *acetate*. [The *sulphate* is most commonly used in the United States.—R.] Opium owes its narcotic properties chiefly to the presence of morphia in combination with meconic acid. A dose of one grain of a salt of morphia has destroyed life. Dr. Ebertz, of Weilberg, met with a case in which an overdose of the hydrochlorate, supplied by mistake for quinine, destroyed the life of a lady in from forty to fifty minutes. Symptoms of narcotism appeared in a quarter of an hour. A very full account of the appearances and analysis will be found in Eulenberg's "Vierteljahrs.," 1873, 1, p. 281.

Chemical analysis. Opium.—There are no means of detecting opium itself, either in its solid or liquid state, except by its smell, taste, and other physical properties, or by giving a portion of the suspected substance to an animal, and observing whether any narcotic effects are produced. The smell is said to be peculiar, but a similar smell is possessed by lactucarium, which contains neither meconic acid nor morphia. The odor is a good concomitant test of the presence of the drug, whether it be in a free state, or dissolved in alcohol or water, but it is not perceptible when the solution is much diluted. The taste is bitter. The analysis in cases of poisoning by opium, is therefore limited to the detection of morphia and the acid with which it is combined—meconic acid.

Morphia.—Morphia may be identified by the following properties: 1. It crystallizes in hexahedral prisms, which are white and perfect, according to their degree of purity. (Fig. 25.) The crystals obtained by adding weak ammonia to a solution of morphia in hydrochloric acid vary in form. When slowly produced they sometimes present the forms represented in the engraving, Fig. 26. 2. When heated on platinum, the crystals melt, become dark-colored, and burn like a resin, with a yellow smoky flame, leaving a carbonaceous residue. If this experiment is per-

formed in a small reduction tube, it will be found, by employing test paper, that ammonia is one of the products of decomposition. 3. It is scarcely soluble in cold water, requiring one thousand parts to dissolve it; it is soluble in one hundred parts of boiling water, and the hot solution has a faint alkaline reaction. By its great insolubility in water, it

80 diameters.

Fig. 26.

Crystals of morphia obtained by adding ammonia to a solution of the hydrochlorate, magnified 124 times.

is readily known from its salts. It is not very soluble in ether or chloroform, thus differing from narcotina; but it is dissolved by forty parts of cold, and rather less than this quantity of boiling alcohol. It is dissolved by a solution of potash or soda, from which it cannot be removed by ether. It is very soluble in acetic ether, and this liquid has been employed for the purpose of separating morphia from organic liquids. 4. It is easily dissolved by a very small quantity of all diluted acids, mineral and vegetable. 5. Morphia and its solutions have a bitter taste. 6. The salts of morphia are not precipitated in a crystalline form by solutions of sulphocyanide of potassium, ferricyanide of potassium, or chromate of potash. In this respect they are strikingly distinguished from the salts of strychnia, which give well-made crystalline precipitates with these three reagents. Like all alkaloids, the morphia in solution is thrown down white by the chloriodide of potassium and mercury (made by dissolving sixteen grains of corrosive sublimate and sixty grains of iodide of potassium in four ounces of water). This liquid precipitates albumen; hence this substance, if present, should be removed by boiling the liquid before applying the test.

Tests.—In order to apply the chemical tests for morphia, the alkaloid may be dissolved in a few drops of a diluted acid, either the acetic or the hydrochloric. If the hydrochlorate or the acetate of morphia is presented for analysis, the salt may be at once dissolved in a small quantity of warm water. The tests for this alkaloid are the following: 1. *Nitric acid*. This, when added to a moderately strong solution of a salt of morphia, produces slowly a deep orange-red color. If added to the crystals of morphia or its salts, nitric oxide is evolved: the morphia is entirely dissolved, and the solution acquires instantly the deep red color above described—becoming, however, lighter by standing. In order that this effect should follow, the solution of morphia must not be too much diluted, and the acid must be strong and added in rather large quantity.

The color is rendered much lighter by boiling; therefore the test should never be added to a hot solution. 2. *Iodic acid* with *sulphide of carbon*. A strong solution of iodic acid should be mixed with its volume of sulphide of carbon. There should be no change of color. On adding a small quantity of these mixed liquids to morphia or its salts, either solid or in solution, the iodine is separated from the iodic acid and dissolved by the sulphide, which sinks to the bottom, acquiring a pink or red color, varying in its intensity according to the quantity of morphia present. This reaction distinguishes morphia from the other alkaloids, which do not decompose iodic acid. The presence of morphia may be thus easily detected, in spite of the presence of organic matter, in one drop of the tincture of opium, in chlorodyne, nepenthe, or other opiate liquids. If sulphide of carbon is not used, iodine may be detected by its odor. 3. *Sulphomolybdic acid*. This is made by dissolving with a gentle heat eight grains of powdered molybdate of ammonia in two drachms of pure and strong sulphuric acid. The liquid should be freshly prepared and kept from contact with air and organic matter. When one or two drops are rubbed with *dry* morphia or any of its salts an intense reddish purple or crimson color is produced. This changes to a dingy green and ultimately to a splendid sapphire blue. [The action on *salicine* strongly resembles that produced by morphia.—R.] 4. *Sulphuric acid* and *bichromate of potash*. When strong sulphuric acid is poured on pure morphia in a solid state, there is either no effect, or the alkaloid acquires a light pinkish color. On adding to this a drop of solution of bichromate of potash, or a small fragment of a crystal, it immediately becomes green (from oxide of chromium), and retains this color for some time. [Morphia in the solid state produces with neutral perchloride of iron a deep blue color.—R.]

Meconic Acid.—This is a solid crystalline acid, seen commonly in scaly crystals of a pale reddish color. It is combined with morphia in opium, of which, according to Mulder, it forms on an average six per cent.; and it serves to render this alkaloid soluble in water and other menstrua. *Tests*.—Many tests have been proposed for meconic acid; but there is only one upon which any reliance can be placed, namely, the *perchloride* or *persulphate of iron*. This test produces, even in a diluted solution of meconic acid, a deep red color; and it is owing to the presence of this acid that a salt of iron strikes a red color in tincture and infusion of opium, as well as in all liquids containing traces of meconate of morphia. The red color of the meconate of iron is not easily destroyed by diluted mineral acids, by a solution of corrosive sublimate, or by chloride of gold, but it is by sulphurous acid and chloride of tin. In liquids containing tannic acid, *e. g.* tea or beer, the action of this test is obscured; but a small quantity of dilute sulphuric acid will remove the tannate of iron and bring out the red color of the meconate.

Detection of opium in organic mixtures.—Opium itself may be regarded as an organic solid, containing the poisonous salt which we wish to extract. It is not often that, in fatal cases of poisoning by opium or its tincture, even when these are taken in large quantity and death is speedy, we can succeed in detecting meconate or morphia in the stomach. The poison is probably removed by vomiting or absorption. Although this absence of the poison from the stomach is now a well-known fact,

there is a popular prejudice that unless found, there is a failure of proof that the death was caused by opium. In the cases of young children who are killed by a very small quantity of this drug, it is the exception to the rule to find any trace of opium, and still more rarely any indication of the presence of its constituents, morphia and meconic acid. Its detection must in all cases depend on the quantity taken, the rate of absorption, and the time during which the person survived. Plain as these reasons for its disappearance are, we occasionally find that they are entirely ignored by a class of analysts called for the defence, and a doubt is raised in the minds of a jury on a question on which there should be no doubt. At the trial of *Chantrelle* before the High Court of Justiciary, Edinburgh, May, 1878, no trace of opium was found in the body, but there was distinct evidence of the presence of morphia and meconic acid, in certain stains on the sheets of the bed on which the deceased was lying. Although made a strong point for the defence, the absence of opium from the stomach was really an unimportant item in the case. The evidence tended to show that the poison had been administered in the form of fluid extract—a form most favorable to absorption; that the quantity administered was small; that the deceased survived fifteen or sixteen hours, and that she had vomited during this time. These conditions are all consistent with the rapid removal of opium from the stomach. The evidence which was here wanting, was fully supplemented by the detection of morphia and meconic acid in the stains on the sheets. The prisoner was convicted and executed in spite of the strenuous efforts made to invalidate the medical evidence.

If the matter is solid, it should be cut into small slices; if liquid, evaporated to an extract; and, in either case, digested with a large quantity of rectified spirit slightly acidulated with acetic acid. The residue should be well pressed in linen; the alcoholic liquid should then be evaporated in a water-bath until it is almost dry. The residue should be digested in water filtered and treated with acetate of lead, until there is no further precipitation. This liquid should be boiled and filtered: meconate of lead is left on the filter, while any morphia passes through under the form of acetate. The surplus acetate of lead, dissolved in the filtered liquid (containing the morphia), should now be precipitated by a current of sulphuretted hydrogen, the black sulphide of lead separated by filtration, and the filtered liquid evaporated at a very gentle heat to an extract, so that any sulphuretted hydrogen may be entirely expelled. On treating this extract with alcohol, the acetate of morphia, if present in sufficient quantity, may be dissolved out and tested. If the alcoholic liquid is still much colored, it may be again evaporated and taken up by water. Animal charcoal deprives it of color, but at the same time it removes the morphia if this is in small quantity. If there is a sufficient quantity of pure acetate present, the addition of a drop of solution of ammonia to a portion of the liquid on a slide, will produce crystals of the form of slender prisms which are somewhat deliquescent. The remainder may be tested by the nitric and iodic as well as by sulpho-molybdic acid. The prismatic crystals obtained under these circumstances have nothing peculiar or definite in form. At the *Chantrelle* trial in Edinburgh (1878), it was stated by an analyst that the crystals furnished better evidence of the presence of morphia than the colored reactions

of the acids. This statement is against all experience and authority. Admitting that prismatic crystals of morphia could be obtained from a few slight stains of opium on a sheet, no medical jurist would rely upon the form of these crystals as evidence of the presence of morphia until after he had tested them by one or more of the acids above mentioned. This frivolous objection to the chemical evidence was exposed and set aside in the cross-examination of the witness.

Meconic Acid.—The *meconate* of lead left on the filter and dried is readily decomposed by boiling it with a small quantity of diluted sulphuric acid [or by sulphuretted hydrogen.—R.]; and in the filtered liquid, neutralized if necessary by an alkali, the meconic acid is easily detected by the iron-test. The detection of *meconic acid* is most important, for this has been found in no substance but opium, and the tests for it are more certain than those applied to morphia. *Morphia* may be obtained in an impure state as a precipitate by adding ammonia to a concentrated solution of the opiate extract. It may be then purified by alcohol, and tested.

Trial tests for both the alkaloid and acid should be first applied to the organic liquid, which may for this purpose be submitted to dialysis (see p. 109). The smell of opium may be entirely absent. Meconic acid may be detected by the action of a persalt of iron on the organic liquid diluted; and morphia may be found by adding to a portion of this liquid, a mixture of iodic acid and sulphide of carbon. The sulphide acquires a pink color by dissolving the iodine set free by morphia or its salts. The chief difficulty in the detection of meconic acid and morphia is that the alkaloid does not form more than one-tenth part of opium, and the quantity of opium in an organic liquid is generally very small.

NEPENTHE.—This is an opiate compound consisting of citrate of morphia and opium dissolved in sherry wine and rectified spirit, with a proportion of water which brings it to the strength of tincture of opium. Morphia is readily detected in it by a mixture of iodic acid and sulphide of carbon; and the meconic acid gives the usual red color with a persalt of iron, when the darkening effect produced by the tannic acid of the sherry is removed by diluted sulphuric acid.

CHAPTER XVII.

PRUSSIC ACID.—SYMPTOMS AND APPEARANCES.—TESTS FOR THE ACID.—PROCESS FOR ORGANIC MIXTURES.—CYANIDE OF POTASSIUM.—ESSENTIAL OIL OF BITTER ALMONDS.—NITROBENZOLE.

HYDROCYANIC OR PRUSSIC ACID.

Symptoms.—This acid has a hot bitter taste and an odor resembling that of bitter almonds diluted. The time at which the symptoms of poisoning commence varies, but it is generally within a few minutes after the poison has been swallowed. When a large dose has been taken, as from half an ounce to an ounce of the diluted acid, the symptoms usually

commence in the act of swallowing, or within a few seconds. It is rare that their appearance is delayed beyond *one or two minutes*. When the patient has been seen at this period, he has been perfectly insensible, the eyes fixed and glistening, the pupils dilated and unaffected by light, the limbs flaccid, the skin cold and covered with a clammy perspiration; there is convulsive breathing at long intervals, and the patient appears dead in the intermediate period; the pulse is imperceptible, and involuntary evacuations are occasionally passed. The respiration is slow, deep, gasping, and occasionally heaving or sobbing. It is generally convulsive, but when the coma or insensibility is profound, it may be stertorous. This was observed in a case which occurred to Sir R. Christison. ("Edinburgh Monthly Journal," February 1850, p. 97.) Convulsions of the limbs and body with a spasmodic closure of the jaw are sometimes noticed among the symptoms.

Appearances.—The body when seen soon after death often exhales the odor of prussic acid; but if it has remained exposed before it is seen, and if it has been exposed to the open air or in a shower of rain, the odor may not be perceptible; again, the odor may be concealed by tobacco-smoke, peppermint, copaiba, or other powerful odors. In a case in which a person poisoned himself with two ounces of the acid, and his body was examined twenty-eight hours after death, the vapor of prussic acid, which escaped on opening the stomach, was so powerful that the inspectors were seized with dizziness. In cases of suicide or accident, the vessel out of which the poison has been taken will commonly be found near; but there is nothing to preclude the possibility of a person throwing it from him in the last act of life, or even concealing it if the symptoms should be delayed. (See case by Sir R. Christison.) Owing to the great volatility of the poison, the vessel, if left uncorked, may not retain the odor when found. Putrefaction is said to be accelerated in these cases; but from what I have been able to collect, there seems to be no ground for this opinion. *Externally*, the skin is commonly livid, or is tinged of a violet color; the nails are blue, the fingers clenched, and the toes contracted: the jaws firmly closed, with foam or froth about the mouth, the face often pale, but sometimes bloated and swollen, and the eyes have been observed to be wide open, fixed, glassy, very prominent and glistening, with the pupils dilated; but a similar condition of the eyes has been observed in other kinds of violent death. *Internally*, the venous system is gorged with dark-colored liquid; the stomach and intestines may be in their natural state; but in several instances they have been found more or less congested. The mucous membrane of the stomach of a dog which died in a few minutes from a dose of three drachms of Scheele's acid, was intensely reddened throughout, presenting the appearance met with in some cases of arsenical poisoning.

The *smallest* dose of this acid which is reported to have caused death was in a case which occurred to Mr. Hicks. ("Med. Gaz." vol. 35, p. 896.) A healthy adult woman died in twenty minutes from a dose equivalent to *nine-tenths* of a grain of anhydrous prussic acid. This corresponds to about *twenty grains* of Scheele's acid. In a case reported by Mr. T. Taylor ("Med. Gaz." vol. 36, page 104), a stout healthy man swallowed this dose, *i. e.* nine-tenths of a grain, by mistake, and

remained insensible for *four hours*, when he vomited and began to recover. From the facts hitherto observed, we shall not be wrong in assuming that a quantity of Scheele's acid (at five per cent.) above twenty grains (*i. e.* one grain of anhydrous acid), or an equivalent proportion of any other acid, would commonly suffice to destroy the life of an adult. This I believe to be the nearest approach that we can make to the *smallest fatal dose*.

When a dose of two drachms and upwards has been taken, we may probably take the average period for death at from *two to ten* minutes. In Mr. Hicks's case, twenty grains of Scheele's acid destroyed life in twenty minutes. It is only when a dose is just in a fatal proportion, that we find a person to survive from half an hour to an hour. In this respect, death by prussic acid is like death by lightning, the person in general either dies speedily or he recovers altogether. Before the access of insensibility the person often possesses a wonderful power of exertion and locomotion, perhaps in a state of half-consciousness. Thus he may be able to cork and conceal the bottle from which he has swallowed the poison, or he may run several yards before falling. Due allowance must be made for the performance of these voluntary acts. (See case by Dr. Tripe, "Brit. Med. Jour." Jan. 1877, p. 11.)

Chemical analysis.—Prussic acid is limpid like water; it possesses a faint acid reaction, and its vapor has a peculiar odor, which when the acid is concentrated, although not at first perceptible, is sufficient to produce giddiness, insensibility, and other alarming symptoms. The tests which are best adapted for the detection of this poison, either in liquid or vapor, are equally applicable whether the acid is concentrated or diluted; and, so far as the detection of the *vapor* is concerned, whether the acid is pure or mixed with other liquids. *In the simple state*, the tests are three in number: the *Silver*, the *Iron*, and the *Sulphur* tests. 1. *The Silver Test. Nitrate of Silver.*—This yields, with prussic acid, a dense white precipitate, speedily subsiding in heavy clots to the bottom of the vessel, and leaving the liquid almost clear. The precipitate is identified as cyanide of silver by the following properties: *a.* It is insoluble in cold nitric acid; but when drained of water, and a sufficient quantity of the strong acid is added, it is easily dissolved on boiling. *b.* It evolves prussic acid when digested in hydrochloric acid. *c.* The precipitate, when *well-dried*, and heated in a small reduction-tube, yields cyanogen, which may be burnt as it issues, producing a rose-red flame with a blue halo. This is a well-marked character, and at once identifies the acid which yielded the precipitate as prussic acid. Five grains by weight of the dry precipitate correspond to one grain of anhydrous prussic acid, to twenty grains of Scheele's acid, and to fifty grains of the British pharmacopœial acid.

For the detection of prussic acid in *vapor*, hold over the liquid a watch-glass moistened in the centre with a drop of a solution of nitrate of silver. Cyanide of silver, indicated by the formation of an opaque white film in the solution, is immediately produced, if the acid is only in a moderate state of concentration. One drop of a diluted acid containing less than 1-50th of a grain of the anhydrous acid produces speedily a visible effect. When the prussic acid is more diluted, a few minutes

are required; and the opaque film begins to show itself at the edges of the silver solution. In this case the action may be accelerated by the heat of the hand. If the vapor is allowed to reach the nitrate of silver gradually, and much diluted with air, then instead of the opaque film of cyanide of silver, crystals well defined under the microscope will be slowly produced, and these will constitute an additional proof of the presence of the acid in a state of vapor. As shown in the illustration, Fig. 27, these crystals have the form of slender prisms with oblique terminations. They often hang together in groups, and generally require a high magnifying power to render them visible. 2. *The Iron Test.*—The object of the application of this test, is the production of *Prussian Blue*. Add to a small quantity of the suspected poisonous liquid a few drops of potash, and of a solution of green sulphate of iron [that has been exposed to the air for some time to partially peroxidize it.—R.]. A dirty green or brownish precipitate falls; on shaking this for a few minutes, and then adding diluted hydrochloric or sulphuric acid, the liquid becomes blue, and Prussian blue, of its well-known color, unaffected by diluted acids, slowly subsides. If the prussic acid is in

Fig. 27.

Crystals of cyanide of silver from the vapor of prussic acid magnified 124 diameters.

small quantity, the liquid is at first yellow, from the salt of iron formed; it then becomes green, but the precipitate ultimately subsides so as to appear of a deep blue color in the mass. The iron-test may be employed for the detection of the vapor of prussic acid, by the same method as that described in speaking of the silver-test. For this purpose we place a few drops of a solution of potash in a watch-glass or saucer, and invert it over the suspected liquid. After a few minutes' exposure, a drop of solution of green sulphate of iron may be added, and then a drop of diluted hydrochloric acid, when Prussian blue will appear. The silver and the iron-tests may be easily conjoined in

testing the same quantity of poison. If the precipitated cyanide of silver, obtained by the addition of nitrate of silver to the suspected liquid, is dried and then moistened with strong hydrochloric acid, the vapor may be collected in a watch-glass or saucer, on the plan above described. Prussian blue will be procured, and thus corroborate the action of the silver-test. 3. *The Sulphur Test.*—Some years since, Liebig proposed the following process for detecting prussic acid as a liquid. ("Oesterreichische Med. Wochenschrift," März 27, 1847, p. 396.) A small quantity of the bisulphide of ammonium is added to a few drops of a solution of prussic acid, and the mixture is gently warmed; it becomes colorless, and, on evaporation, leaves crystals of sulphocyanate of ammonia—the sulphocyanic acid being indicated by the intense blood-red color produced on adding to the dry residue a solution of nearly neutral persalt of iron; this red color immediately disappears on adding a few drops of a solution of corrosive sublimate.

The great utility of the *sulphur-test*, however, is in its application to the detection of the minutest portion of prussic acid when in a state of *vapor*. In this respect it surpasses any other process yet discovered. In order to apply it, we place the diluted prussic acid in a watch-glass, and invert over it another watch-glass, having in its centre one drop of the bisulphide of ammonium. No change apparently takes place in the sulphide; but if the upper watch-glass is removed after the lapse of from half a minute to ten minutes, according to the quantity and strength of the prussic acid present, crystallized sulphocyanate of ammonia will be obtained on gently evaporating the drop of liquid to dryness. With an acid of from three to five per cent. the action is completed in ten seconds. The addition of one drop of the neutral persulphate of iron (free from nitric acid) to the dried residue, brings out the blood-red color instantly, which is intense in proportion to the quantity of sulphocyanate present. I have elsewhere made some remarks on the application of this process for the detection of prussic acid. (See "Med. Gaz." 1847, vol. 39, p. 765.)

Prussic Acid in organic liquids. Detection by vapor without distillation.—The organic liquid may be placed in a short wide-mouthed bottle, to which a watch-glass has been previously fitted as a cover. The capacity of the bottle may be such as to allow the surface of the liquid to be within one or two inches of the concave surface of the watch-glass. The solution of *nitrate of silver* is then used as a trial-test for the vapor in the manner above described. If the 1-200th of a grain of prussic acid is present, and not too largely diluted, it will be detected (at a temperature of 60°) by the drop of nitrate of silver being converted into an opaque white or crystalline film of cyanide of silver, the chemical change commencing at the margin. We may then substitute for the nitrate of silver the bisulphide of ammonium, and proceed in the manner above described. In cold weather it may be necessary to place the bottle in a basin of warm water. If the solution of silver is tarnished by sulphuretted hydrogen as a result of putrefaction, the sulphur-test alone should be used. By this process I have detected prussic acid in the stomach of a person poisoned by it, as late as twelve days after death. After the stomach had been exposed for a few days longer, the acid had entirely disappeared.

If traces of the poison are thus found, then the organic liquid should be distilled in a water-bath, at 212° , and about one-fourth of the contents of the flask collected in a receiver kept cool by water. The tests may now be applied to the distilled liquid, which will have the odor of prussic acid.

[In the search for *free* prussic acid in the stomach by distillation, the analyst should avoid the use of sulphuric acid, since this acid will decompose the sulphocyanide existing in the saliva (which would be likely to be found in the stomach), as also any ferrocyanide, and thereby evolve *traces* of prussic acid.

In the celebrated case of Dr. Schœppe, tried at Carlisle, Pa., in 1868 and 1872, this was made a capital point in the defence. The prosecution endeavored to sustain the charge of poisoning by prussic acid (although there was not one characteristic symptom of this poison

exhibited before death), by the allegation that the analyst had discovered *faint traces* of it in the liquid obtained by distilling the stomach *along with sulphuric acid*. It was very properly objected that the addition of this acid would render it impossible for the chemist to determine whether any *free* prussic acid had been originally present, or not; even admitting the reliability of the “faint traces” alleged.

One of the latest American authorities (“Wharton and Stillé’s Med. Jurisp.,” 1873, p. 515), speaking of this acid, says “it may certainly become a question of serious import whether the traces of it found afterwards may not be due to some other cause than its ingestion into the stomach. Thus, if the contents of the stomach be subjected to distillation *with an acid*, it may possibly happen that the sulphocyanide of potassium which sometimes exists in minute traces in the saliva, may be decomposed, and evidence of prussic acid be thus obtained.”—R.]

In the tissues.—Soon after death the poison may be easily detected in the blood, secretions, or any of the soft organs, by placing them in a bottle, and collecting the vapor in the manner already described. This will be found more convenient and satisfactory than the process by distillation. In the case of a dog poisoned by a large dose of prussic acid, Mr. Hicks brought to me the stomach after it had been exposed twenty-four hours, and thoroughly washed under a current of water, and yet the poison was readily detected by placing the whole organ in a bottle, and absorbing the vapor by nitrate of silver. This shows how completely the animal tissues at death are penetrated by prussic acid, and how firmly for a time it is retained by them. The poison has been thus discovered, in experiments on animals, in the blood and even in the serous exhalation of the chest.

If the body is in a putrefied state, the residuary prussic acid may have been converted into fixed sulphocyanide of ammonium. In order to detect this salt in the stomach or its contents, we should digest the parts finely cut up in hot alcohol, filter the alcoholic liquid evaporate to dryness, and take up any crystalline residue with water. A solution of a persalt of iron added to this solution will indicate the presence of a sulphocyanide, by imparting to it an intensely red color. (See p. 210.)

CYANIDE OF POTASSIUM.

Symptoms.—This salt has a bitter taste, producing first a sense of coldness on the tongue, followed by a feeling of constriction, and burning heat in the throat. It is one of the most formidable poisons known to chemists. It has destroyed life in a quarter of an hour. A dose of five grains has proved fatal in three instances. In one case the person died in two hours. (“Chem. News,” Sept. 5, 1863.) The symptoms which the cyanide produces are similar to those occasioned by prussic acid: insensibility, spasmodic respiration, convulsions, with tetanic stiffness of the jaws and body. They appear in a few seconds or minutes, and run through their course with great rapidity.

Dr. Auer, of Lundshut, met with the following case, which is remarkable for the early occurrence of symptoms and rapid death. A youth of 16 swallowed a quantity of concentrated solution of the cyanide. He

then suddenly fell in a state of unconsciousness into the arms of a friend who was present. His breathing was deep and laborious, his eyes rolled convulsively and the whole of his body was violently convulsed. These symptoms lasted for about a minute, and he then appeared to be in a lifeless state. Dr. Auer saw him immediately. He was then lying on the floor dead, his legs and arms stretched out and his body raised in a state of opisthotonos. Death had taken place in about three minutes. There was no smell of bitter almonds in any of the cavities of the body. The mucous membrane of the stomach towards the cardiac and pylorus was of a deep cherry red color. There was general venous congestion of the organs. The cyanide was detected in the stomach. ("Friedreich's Blätter der ger. Med.," Dec. 1878, p. 436.)

Appearances.—In a case in which an inspection of the body was made two days after death, there was no remarkable odor: the muscles were rigid; the face and forepart of the trunk pale; the back part livid, except those portions which had sustained pressure. The fingers and toes were convulsively bent inwards, the nails blue, eyelids half-closed, lips pale, the vessels of the brain filled with bluish-red (blaurothem) blood. On making a section of the brain and spinal marrow, numerous bloody points were observed. The lungs were congested posteriorly, and on cutting into them, a strong odor of bitter almonds was perceived. A yellowish mucus was found in the stomach, which yielded on analysis cyanide of potassium. The mucous membrane was reddened near the intestinal end. The poison was not detected in any part of the body except the contents of the stomach and intestines. (Caspar's "Wochenschrift," Oct. 4, 1845, 657.)

Cyanide of potassium has a local chemical action upon the skin; and if this is abraded or wounded, it may be absorbed and produce serious effects. Some accidents of this kind have occurred in the practice of photography. ("Ann. d'Hyg.," 1863, vol. 1, p. 454.) This poison has been found as an impurity in reduced iron (*Ferrum redactum*).

Analysis.—This substance is usually seen in hard white masses. It is deliquescent, and very soluble in water: the solution, when pure, is colorless, and has a strong alkaline reaction, a soapy feel, and a powerful odor of prussic acid. It is not very soluble in cold alcohol. 1. It is decomposed by all acids, and prussic acid is set free. 2. The potash is precipitated by tartaric acid and chloride of platinum. 3. It gives a white precipitate with nitrate of silver, which, when dried and heated, possesses all the properties of cyanide of silver (ante, p. 209). This precipitate is easily redissolved by a slight excess of the solution of cyanide of potassium. 4. If a solution of photo-sulphate of iron is added to a solution of the cyanide of potassium, and after agitation the mixture is treated with diluted sulphuric acid, Prussian blue will be produced.

Ferrocyanide of potassium is not a poison, but when mixed with any acid, prussic acid is set free and it may then destroy life. Dr. Volz, of Ulm, met with a case in which a man destroyed himself by swallowing a mixture of hydrochloric acid with the ferrocyanide of potassium. Prussic acid was produced in his body and killed him suddenly. There were the marks of the action of hydrochloric acid on the mouth, œsophagus and stomach, but the symptoms proved that the man had died from the

generated poison. Sownenschein describes a case in which similar effects were produced by a mixture of tartaric acid with the solution of ferrocyanide. This also proved fatal.

ESSENTIAL OIL OF BITTER ALMONDS.

This liquid, which is used for the purpose of giving flavor and odor to confectionery, owes its poisonous properties chiefly to the presence of prussic acid. It contains a variable quantity of this poison, which has been found in it in a proportion of from eight to twelve per cent. *Almond flavor* or essence of peach kernels contains one drachm of the essential oil to seven drachms of rectified spirit. The bitter almond itself operates as a poison. A boy who had eaten several almonds was found unconscious, cyanotic, and pale, with eyelids closed and pupils moderately dilated. The arms were stiffened with tonic spasm. Trembling low pulse, not perceptible. Vomiting excited by emetics. He went to sleep, and recovered in eighteen hours. ("Med. Times and Gaz.," Jan. 1878.) Peach kernels operate in a similar manner. One ounce of the kernels is considered to be equal to one grain of prussic acid.

Symptoms.—The following may be taken as a summary: insensibility, lividity of the face, eyes glassy, prominent, fixed, and staring; pupils dilated and insensible to light; jaws spasmodically closed; frothy mucus about the mouth and in some cases vomiting; coldness of the skin; heaving and intermittent respiration, in some instances stertorous; absence of the pulse; head spasmodically drawn backwards, and sometimes the trunk; general relaxation of the limbs; an odor of bitter almonds about the mouth.

Appearances.—In one fatal case nine hours after death no odor of almonds was perceptible in the chest, head, or heart, nor in the blood. The lungs and heart were healthy. The vessels of the brain were congested, and there was a general effusion of serum on the hemispheres. The lining membrane of the stomach was much congested. On opening it, the odor of bitter almonds was quite perceptible. (See "Prov. Med. Jour.," Sept. 11, 1844, p. 364.) The blood with which the venous system is gorged, is generally liquid and of a dark color.

Analysis.—The *essential oil*, which is sometimes called peach-nut oil, is colorless when pure, but it commonly has a pale yellow color, and a strong odor of bitter almonds, by which it may be at once identified. It has a hot burning taste, and a feebly acid reaction. The smell and taste are generally sufficient for its identification; but nitrobenzole possesses a similar odor, and has been mistaken for it. It produces, when dropped on paper, a greasy stain, which does not entirely disappear by the application of heat. It has a sp. gr. of 1.043; hence it sinks in water, which dissolves about one-thirtieth part. It is soluble in alcohol and ether in all proportions. When mixed with a few drops of strong sulphuric acid, it forms a rich crimson-red liquid, which, if exposed to air, acquires a yellow color. Prussic acid may be detected in it by dissolving the oil in alcohol and adding a solution of potash and green sulphate of iron. On the addition of a diluted acid, Prussian blue remains.

NITROBENZOLE (ESSENCE OF MIRBANE).

This liquid, which is largely employed as a substitute for the essential oil of bitter almonds in perfumery and confectionery, has now taken its place among narcotic poisons. It has been mistaken for essential oil of bitter almonds, but its mode of operation is different. In 1859, the late Professor Casper, of Berlin, published an account of this liquid under the name of "A New Poison." ("Vierteljahrsschrift," B. 16, p. 1.)

Symptoms.—The cases which have yet occurred show that this is an insidious poison both in liquid and vapor. There is a burning taste in the mouth, followed by a sensation of numbness and tingling in the tongue and lips. There is no immediate insensibility, as in poisoning by prussic acid, and there are no convulsions. The eyes are bright and glassy, the features pale and ghastly, the lips and nails purple, as if stained by blackberries, the skin clammy, and the pulse feeble. There is a powerful odor resembling that of oil of bitter almonds. The mind may be clear for an hour, or several hours, after the poison has been swallowed. The patient then suddenly becomes unconscious, the jaws fixed, the hands clenched and blue, and the muscles rigid and convulsed. In one case there was vomiting of a liquid having the odor of nitrobenzole. The breathing was slow and the pulse scarcely perceptible. Reaction set in, in about eleven hours, and recovery took place. ("Guy's Hospital Reports," Oct. 1864, p. 192.) In a fatal case examined by the late Dr. Letheby, the *appearances* were as follows: the superficial vessels were much gorged with blood, which was black and fluid. The lungs were congested, the cavities of the heart were full of blood, the liver was of a purple color, the brain and its membranes were congested, and there was much bloody serosity in the ventricles. Dr. Lehmann has more recently reported the symptoms and appearances in a fatal case. ("Ann. d'Hyg.," 1873, 1, p. 444.)

This compound has a narcotic action, but it differs from the ordinary narcotics in its powerful and persistent odor, which would render it difficult for a person to administer it unknowingly to another, either in liquid or vapor; in the production of profound coma at an uncertain interval after the stupor; and in the rapidly fatal effects when coma has followed. It operates powerfully as a poison in vapor as well as in a liquid state; but so far as cases have been yet observed in the human subject, the symptoms resembling those of the first stage of narcotic poisoning have very soon appeared. The rapidly fatal cases only would be likely to be mistaken for apoplexy, but in these the poison would be detected by its odor. ("Ann. d'Hyg.," Oct. 1879, p. 382.)

Analysis.—Nitrobenzole is a pale lemon-colored liquid, of a strong odor resembling that of bitter almonds. It has a pungent hot disagreeable taste. It gives to confectionery and soap the smell of oil of bitter almonds. It gives a greasy stain to paper. It sinks in water, and is partly dissolved, imparting to it a yellowish color. It is soluble in alcohol, ether, and chloroform, but when agitated with water, it is in great part separated from its ethereal and chloroformic solutions. It burns with a yellow smoky flame. It yields no Prussian blue when mixed with sulphate of iron, alcohol, and potash. It is distinguished from all

other liquids, excepting the essential oil of almonds, by its odor, and from this oil by the following test: Pour a few drops of each on a plate, and add a drop of strong sulphuric acid. The oil of almonds acquires a rich crimson color with a yellow border, the nitrobenzole produces no color. In order to separate it from organic liquids, they may be acidulated with sulphuric acid, and submitted to distillation.

CHAPTER XVIII.

ALCOHOL.—ETHER.—CHLOROFORM.—HYDRATE OF CHLORAL.—CAMPHOR.—
TOBACCO.—NICOTINA.—COCCULUS INDICUS.—PICROTOXINE.—FUNGI.—
HENBANE.

ALCOHOL.

Symptoms.—In general, the symptoms produced in poisoning with alcohol come on in the course of a few minutes. There is confusion of thought, with inability to stand or walk, a tottering gait and giddiness, followed by stupor and coma. Should the person recover from this stage, vomiting supervenes. The insensibility produced by alcohol may not come on until after a certain period, and then suddenly. Sir R. Christison met with an instance in which a person fell suddenly into a deep stupor, some time after he had swallowed sixteen ounces of whiskey; there were none of the usual premonitory symptoms. In another instance, a person may apparently recover from the first effects, then suddenly become insensible and die convulsed. There is a ghastly or vacant expression on the features, which are sometimes suffused and bloated, the lips are livid, and the pupils are dilated and fixed; if they possess the power of contracting under the influence of light, it is a favorable sign. The conjunctivæ or whites of the eyes are generally much suffused. The breath has an alcoholic odor. The more concentrated the alcohol, the more rapidly are the symptoms induced, and they are also more severe in their character. Diluted alcohol commonly produces a stage of excitement before stupor, while in the action of concentrated alcohol there may be profound coma in a few minutes. [It is important to distinguish between these symptoms and those produced by concussion of the brain, and by opium poisoning.—R.] The cause of death may be generally traced to congestion of the brain, or lungs, or both. Sometimes a large dose may be taken without causing death. A child, aged four, swallowed between two and three ounces of brandy. He was found insensible, the breathing was scarcely perceptible, and the pupils were widely dilated. Under treatment he recovered in two days. (“Lancet,” 1872, 2, p. 76.) In December, 1878, a child, aged twelve, died from the effects of drinking nearly half a pint of whiskey. The presence of amylic, butylic, or propylic alcohol adds to the poisonous effects of whiskey and brandy.

Dr. Beaumetz assigns three periods to acute alcoholic poisoning. 1st,

a period of depression; 2d, a period of reaction; and 3d, of collapse; the periods being modified by the quantity of alcohol taken. As a rule, the three periods succeed each other in a regular manner. In all cases there is a great depression of animal heat, sometimes amounting to one-half of the normal standard. ("Medical Record," 1879.)

Alcohol may act as a poison by its *vapor*. If the concentrated vapor be respired, it will produce the usual effects of intoxication. There is a case on record in which a child two years of age was thrown into an apoplectic stupor by the alcoholic vapor of eau de Cologne. In this manner a child might be destroyed, and no trace of the poison found in the stomach.

Appearances.—The stomach has been found intensely congested or inflamed, the mucous membranes presenting in one case a bright red, and in another a dark red-brown color. When death has taken place rapidly, there may be a peculiar odor of spirits in the contents; but this will not be perceived if the quantity taken was small, or many hours have elapsed before the inspection is made. The brain and its membranes are found congested, and, in some instances, there is effusion of blood or serum beneath the inner membrane (*pia mater*).

Dr. Beaumetz has found among the appearances produced by acute alcoholic poisoning congestion of the lungs, as well as of the membranes of the brain. The mucous membrane of the intestines was softened, and its surface was of a dark reddish color. The blood itself was dark-colored and coagula of variable size were found in the heart. ("Med. Record," 1879.) In chronic poisoning (alcoholism) other appearances present themselves, *i. e.*, disease of the liver and of the heart. The liver becomes dense and granular in its structure, and of a yellowish color (*cirrhosis*); hence, it is commonly called the nutmeg liver. This is so frequent a result of drinking rum spirits that it is known as the drunkard's liver.

It is not often that alcoholic poisoning forms the subject of a criminal charge. Alcohol in any of its ordinary forms as spirits, cannot be administered forcibly to a person in a sufficient quantity to destroy life, without the person being made fully conscious of the attempt and able to resist it. William Palmer, who was convicted in 1856 of the murder of his friend Cook by strychnia, had made an attempt to destroy the life of his brother Walter Palmer, by means of alcohol. He had insured his brother's life for £13,000 in the Prince of Wales Office. Walter Palmer died suddenly at Wolverhampton, in the presence of his brother and of a man of bad character, with whom he had been placed as a lodger. The evidence at the inquest showed that brandy had been freely supplied to Walter by the order of William, and that a bottle of the spirit with a glass was constantly kept at the bedside. Although this had the effect of causing Walter to be almost constantly in a state of intoxication, yet it did not act as a poison to destroy life rapidly. On the 16th of August, 1855, Walter Palmer died very suddenly, and it was proved that shortly before his death, William had procured at a druggist's under a medical prescription, a bottle of Scheele's prussic acid. The half intoxicated state in which the deceased was constantly kept, rendered it an easy matter to administer to him a dose of prussic acid in brandy, and thus to cause sudden death. As the life insurance was only for a term nearly expired,

the death of Walter became necessary, or no claim could be made for the insurance. The policy had been previously assigned by Walter to William for a nominal consideration, but when Walter Palmer made application for the amount, the office, owing to the suspiciously sudden death, refused payment, and William Palmer made no attempt to enforce it. In this case large quantities of alcohol taken voluntarily, but by criminal connivance, failed to destroy life.

A remarkable case which illustrates this mode of poisoning by alcohol has been recently tried in London, and has ended in the conviction of the criminal. (*Reg. v. Paine*, Central Crim. Court, Feb. 1880.) The deceased, a young woman of fortune, had fallen under the influence of the prisoner. He had led her into the habit of drinking raw spirits, in which he himself also indulged. Her intemperance was such as to destroy her health. He brought her to London and took lodgings for her; brandy and other spirits were supplied in large quantity by order of the prisoner. On some occasions it was proved that contrary to the order of a medical man who had been called in shortly before her death, and in spite of the remonstrances of the woman herself, the prisoner had persisted in administering spirits to her. He took no steps to inform her relations of her dangerous state, he prevented her friends from seeing her, and took care that brandy and gin should always be within her reach at the bedside. The motive for this conduct on the part of the prisoner was obvious. By her will and by a deed of gift he had caused her to assign all her property to him. The medical evidence was sufficient to show by the symptoms and post-mortem appearances that the cause of death was owing to the excessive administration of alcohol in the form of raw spirits, and the question for the jury was whether there was an administration with intent to bring about her death, or was the alcohol administered in excessive quantities under circumstances which proved that there was gross criminal negligence. In the first case, even if there was only an acceleration of death, the crime would be murder, and in the second case manslaughter. The prisoner was found guilty of manslaughter, and sentenced to penal servitude for life.

Analysis.—When a large quantity of alcohol has been taken and the case has proved rapidly fatal, the contents of the stomach may retain the odor of alcohol, or of the spirits taken. The odor however is not always perceptible, and it may be easily concealed by other odors. In a case of poisoning with gin, the liquid drawn from the stomach by the pump after seven hours, had no odor. The smell of brandy has entirely disappeared in twelve hours.

The contents of the stomach or the suspected liquid should be distilled in a water-bath, with a proper condensing apparatus attached (Fig. 9, p. 146). If the liquid has an acid reaction, it should be first neutralized with a solution of carbonate of potash or soda. The watery distillate obtained should be mixed with dry chloride of calcium or anhydrous sulphate of copper in sufficient quantity, and submitted to a second distillation in a smaller retort by a water-bath. The liquid obtained by the second distillation should be agitated with rather more carbonate of potash than it will dissolve, in a small tube provided with a stopper, and allowed to stand. A stratum of alcohol, if present, will, after a time,

been opened. In spite of some reaction under treatment, there was no signs of recovery: the breathing became stertorous, and the child died twelve hours after swallowing the liquid. On inspection there was a strong smell of spirit; the mucous coat of the stomach was inflamed, as well as that of the duodenum. The membranes of the brain were highly congested, the vessels containing a large quantity of dark-colored blood. The operation of this liquid resembled that of a mixture of alcohol and ether. Another case of poisoning with this liquid is reported in the "Lancet" of January 4, 1879.

CHLOROFORM.

Symptoms.—Chloroform, when taken in a large dose, appears to affect the system like alcohol, but as a *liquid* it cannot be regarded as an active poison. In one case a man swallowed *four fluidounces*. He was able to walk for a considerable distance after taking this dose, but he subsequently fell into a state of coma—the pupils were dilated, the breathing was stertorous, the skin cold, the pulse imperceptible, and there were great convulsions. He recovered in five days. ("Med. Gaz.," vol. 47, p. 675.) In another case a man swallowed an ounce and a half of chloroform. The stomach pump was used, but he became cyanosed—the pupils were dilated and fixed. The pulse was one hundred and forty-four, the temperature of the body 100° to 102° . He died twenty-six hours after taking it. There was general congestion of the brain and its membranes. There were patches of a bright scarlet color on the mucous membranes of the stomach. ("Med. Times and Gaz.," Jan. 1878, p. 36.) A boy, *æt.* 4, was found by his father in a state of total insensibility. It appeared that he had swallowed a *drachm* of chloroform, and soon afterwards laid his head on his mother's lap, and then lost all consciousness. In about twenty minutes he was insensible, cold, and pulseless. Mustard plasters were applied to his legs, they acted well, but produced no impression on the insensibility. His breathing varied: it was sometimes natural, at other times stertorous. He became warmer, his pulse full and regular; after continuing *three hours* in this state, he died calmly without a struggle, in spite of every effort made for his recovery. This is the smallest dose of liquid chloroform that has destroyed life.

Chloroform is rarely used criminally as a poison; the taste and smell are sufficient to give a person warning, and thus to prevent a sufficient quantity being swallowed to cause fatal effects. The attempt has, however, been made. In *Reg. v. Archard*, the prisoner was convicted of administering chloroform to his son, a boy *æt.* 8. (Liverpool Winter Assizes, 1879.)

Chloroform vapor.—This vapor when respired in a concentrated form, is speedily fatal to life. If it is diluted with a certain proportion of air, it produces insensibility, with entire loss of muscular power, in from eight to ten minutes, and the patient rapidly recovers after the vapor is withdrawn. Cases of death from the inhalation of the vapor for surgical purposes are now very numerous, and the symptoms and post-mortem appearances are well marked. ("On Poisons," 3d ed. p. 646; also, "Lancet," April, 1859, pp. 400, 425; also, "Lancet," 1870, vol. 2, pp.

454,886.) In some instances death has taken place within two minutes from the commencement of inhalation. In one in which only *thirty drops* had been inhaled in vapor, the patient died in one minute, and in another so small a quantity as fifteen or twenty drops proved speedily fatal. ("Table of Fatal Cases" by Dr. Warren, U. S. p. 23.) Its fatal effects do not depend so much on the absolute quantity, as on the proportion in which it is breathed in a state of mixture with atmospheric air. It has been stated that the average proportion of this vapor for medicinal purposes should not exceed $3\frac{1}{2}$ per cent., and that $4\frac{1}{2}$ is a maximum quantity to be taken with safety. The proportion should be only slowly increased. The vapor should not be given after a long fast, after a full meal, or while the person is in a sitting or erect posture. ("Ed. Monthly Journ.," Aug. 1864; "Brit. Med. Journ.," Dec. 25, 1875, p. 778.) The vapor of this liquid operating through the lungs has destroyed life more rapidly, and in a smaller dose, than any other poison known. Its fatal operation is sometimes suddenly manifested apparently by an accumulative effect in the blood after the withdrawal of the vapor. In one case witnessed by a friend, the heart suddenly ceased to beat four minutes after the vapor had been withdrawn. The digital arteries which had been divided in the operation ceased to bleed. The man was dead. Two fatal cases are reported in the "Brit. Med. Journ." for August, 1873, p. 230. In one of these a man in good general health died after having inhaled *one drachm* in vapor. Fatal syncope came on suddenly after the chloroform had been withdrawn. In the other case, a lady died at Brighton under the effects of chloroform, while having a tooth extracted. In this case, it is said, there was fatty degeneration of the heart. It is to this condition of a fatty or flabby heart that the fatal effects are usually ascribed. Assuming this to be to some extent the true cause of the fatality, it must be admitted that fatty and flabby hearts have become very common since the introduction of chloroform-vapor for surgical and other purposes! The theory of a flabby heart is quite unnecessary to explain the fatal results occasionally produced by chloroform-vapor, even when administered by experienced persons. In January, 1866, a healthy man died in three minutes from the effects of only two drachms of chloroform in vapor. This occurred on the operating table of a London hospital—the vapor having been administered by a gentleman who had given it previously to 300 or 400 patients. Death was sudden, and took place after some deep inspirations and expirations had been made. It was on this occasion candidly admitted that the body was quite healthy. In this and other cases, either the chloroform was taken in too concentrated a form, or there may have been an idiosyncrasy in the patient to its narcotic poisonous action. Many similar cases have occurred since the previous edition of this work. They will be found recorded in the "Lancet," "British Medical," and other journals. As a preventive of these accidents, Dr. Wachsmith has recommended a mixture of turpentine vapor with that of chloroform. ("Vierteljahrs. der Ger. Med.," April, 1878.)

In cases of alleged robbery and rape, it has been sometimes stated that the person assaulted was rendered suddenly insensible by chloroform; but chloroform-vapor does not produce immediate insensibility without

the risk of causing asphyxia and death. There can be no doubt that several false charges of rape have been made against medical men and dentists under the alleged use of this vapor. In general the statement of the prosecutrix alone has been sufficient to show the falsehood of the charge. In the following case, which is reported to have occurred in New York in November, 1871, this mode of effecting robbery without destroying life appears to have been successful. A lady, while lying in bed, was suddenly seized by two men who covered her face with a towel steeped in chloroform. She endeavored to give an alarm, but the drugged cloth was kept closely to her mouth until she had become insensible. In the morning, when she had recovered, it was found that she had been robbed of a large sum of money and other property.

Analysis.—Chloroform is a heavy colorless liquid, sp. gr. 1.484, neutral in its reaction, sinking in water in heavy oily-looking globules, and only to a slight extent dissolving in this liquid. It has a peculiar fragrant odor, resembling that of apples. It is very volatile, but not combustible, and, like alcohol, dissolves camphor. It may be separated from other liquids by distillation at a low temperature. At a red heat it is resolved into chlorine and hydrochloric acid. On this effect a process has been suggested for separating it from the *blood and tissues*, when it has proved fatal in the form of vapor. The substance supposed to contain chloroform is placed in a flask, the neck of which is fitted with a cork perforated to admit a hard glass tube, bent at right angles, and having a length of from twelve to fifteen inches. The flask is gradually plunged into water at about 160° , and at the same time the middle portion of the tube is heated to full redness by an air-gas jet. At a red heat, chloroform-vapor is decomposed, and chloroform and hydrochloric acid are among the products of its decomposition. Litmus paper applied to the mouth of the tube is reddened; starch paper wetted with iodide of potassium is rendered blue; and nitrate of silver is precipitated white. Two drops of pure chloroform were thus readily detected; and so persistent was the vapor in the closed vessel, that it was detected after one, two, and even three weeks. Two drops added to a quantity of putrefied blood were detected by a similar process after a fortnight, the flask being closed, but the mouth of the tube remaining exposed to air. This method of detecting chloroform by its products appears to be quite satisfactory. In practice, however, it will be found a very difficult matter to detect it, even where we know it has been administered.

HYDRATE OF CHLORAL.

This is a solid crystalline substance which has been much used of late as a substitute for opium. In doses of from twenty to thirty grains, it has been found to operate as a sedative and narcotic, without producing excitement. It has been given in very large doses, sometimes with benefit, but at other times causing dangerous symptoms, followed by sudden death. Medical men who have taken it incautiously have died from its effects. Two instances of this kind are reported in the "*Med. Times and Gaz.*" (1871, 1, p. 367). No remarkable symptoms have preceded dissolution. The person has passed at once from sleep into death.

Symptoms and appearances.—A lady took six doses of thirty grains each. She fell into a sound sleep. Every attempt failed to arouse her, and she slept into death. The principal post-mortem appearance was great congestion of the cerebral vessels. ("Med. Times. and Gaz.," 1871, 1, p. 132.) In another case a lady took in three doses, at intervals of four hours, seventy grains of the hydrate. In two hours after the last dose, she suffered from severe cramps in the legs, a feeling of suffocation, swimming in the head, and inability to regulate her movements. Four hours after the last dose her face was flushed, the eyelids were closed, and the conjunctivæ injected; the pulse was quick (120) and bounding. She was with difficulty roused either to speak or to take food. She recovered in about sixteen hours. ("Med. Times. and Gaz.," 1870, vol. 2, p. 435.) A man took half a drachm of the hydrate at night. He became unconscious almost immediately after swallowing the draught—the face and hands turned livid and cold, and breathing took place only at long intervals; indeed for about five hours death seemed to be impending. He recovered next day. ("Lancet," 1870, vol. 2, p. 402.) A case is reported in the same journal in which a dose of 160 grains was given by mistake to an hospital patient, a middle-aged man. The man recovered, notwithstanding the large dose taken. Another case of recovery after a similar dose has been recently reported by Dr. Fiskard, of Weymouth ("Brit. Med. Jour.," Sept. 1878, p. 437). A young lady swallowed in the form of syrup, one hundred and sixty grains of chloral-hydrate at eight o'clock (in two ounces of the syrup). About three or four hours afterwards she was seen in a state of unconsciousness, lying on her back in bed; pulse 80; regular but small respirations, 28 per minute; pupils moderately contracted, but not altogether insensible to light. She had vomited some viscid yellowish-looking fluid, with no perceptible odor, and a frothy mucus oozed from her mouth. It was not at this time known that she had taken chloral, and it was thought that the symptoms indicated poisoning by morphia. She was temporarily roused by ammonia. She could not swallow. The stomach pump was used, and the stomach freely washed out. Coffee was given by the rectum. Electricity was employed for an hour and a half, when she recovered her consciousness, and stated what she had taken. She made a good recovery.

Dr. N. Smith, of Baltimore, met with two instances in which sudden death followed ordinary doses, and in another case a drachm and a half thrown into the rectum, produced rapidly insensibility and caused death in three hours. ("Lancet," 1871, vol. 2, p. 466.) It has been observed in reference to this drug, that during the sleep produced by it, the pupil is contracted, but that it immediately dilates on the person awaking. In other cases the pupil has been found dilated and insensible to light. These facts show that there is considerable uncertainty in the action of this drug, even when similar doses have been given. A slight overdose may cause sudden death by syncope ("Lancet," 1873, 1, p. 640); and ordinary doses long continued, may seriously affect the mind and body ("Lancet," 1873, 1, p. 789). After an ordinary dose of twenty or thirty grains, a patient has slept for a quarter of an hour, and has then awakened with a sense of deadly faintness, the lips livid, the face pale, the pulse scarcely perceptible, and a feeling of intense exhaustion and impending

dissolution, mingled with delirium, lasting for five or ten minutes. It appears to exert a depressing action on the heart, and in cases of heart-disease it may thus cause sudden death. ("Lancet," 1871, vol. 2, p. 32.) One case proved suddenly fatal by causing paralysis of the heart. ("Lancet," 1871, vol. 1, pp. 227, 440-473.) For the effects of chronic poisoning by this substance, see "Lancet," vol. 1, 1873, p. 695.

From the facts hitherto reported, it is difficult to assign a minimum fatal dose. A dose of *thirty grains* proved fatal in thirty-five hours to a young lady aged twenty, while there have been two cases of recovery in which doses of one hundred and sixty grains were taken, and one in which a man recovered after taking one hundred and eighty grains dissolved in syrup. ("Brit. Med. Jour.," 1875, p. 778.) Recovery in these cases was no doubt greatly owing to treatment.

Analysis.—The hydrate of chloral is a white brittle crystalline solid, of a peculiar odor, and a pungent bitter taste. When heated on platinum it melts and is entirely volatilized without combustion, unless the liquid is turned into the flame. It is not inflammable. Heated in a close tube it melts and does not rapidly solidify. It is distilled over in a liquid form, and after a time it sets into groups of crystals in the glass tube. It is soluble in water, which retains it on cooling, while the alcoholate is again in great part deposited. The solution is not acid, has no bleaching properties, and gives only a faint milkiness on boiling with a solution of nitrate of silver. It is dissolved by strong sulphuric and nitric acids without any change of color. Potash added to the solution while boiling converts it instantly into chloroform, which escapes in copious effervescence, and may be recognized by its peculiar odor. It is by this conversion that hydrate of chloral may be detected in the contents of the stomach. The organic liquid should be rendered alkaline with potash, and the mixture then distilled. The chloroform vapor may be condensed in a cool flask.

CHLORIC ETHER—(*Spiritus Chloroformi*).—This is a mixture of one part, by measure, of chloroform to nineteen parts of rectified spirit. It is given internally in doses of from twenty to sixty minims.

CHLORODYNE.—This is a compound containing chloroform, tincture of opium, and prussic acid. It is mixed with treacle and other substances to conceal its composition. A fatal case from an overdose of this medicine occurred at Oxford in 1871. A lady, æt. 23, had been accustomed to take the liquid for the relief of pain, in doses of as much as sixty drops. She was found dead in bed, and the cause of death was referred by her medical attendant to her having taken two doses without letting a sufficient interval elapse between them. ("Lancet," 1871, vol. 2, p. 697.) From 1860 to 1867 there were four recorded deaths from this compound.

CAMPBOR.

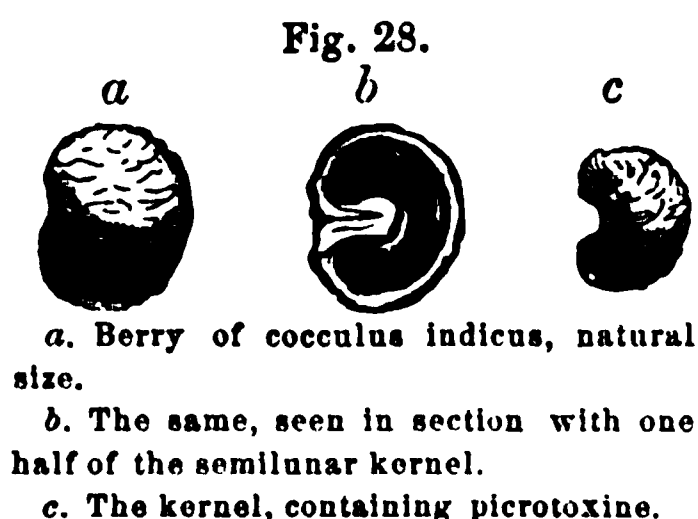

Symptoms and appearances.—Camphor operates on the brain and nervous system. In one case which occurred to Mr. Hallet, a woman swallowed in the morning about *twenty grains* dissolved in rectified spirits of wine and mixed with tincture of myrrh. In half an hour she was suddenly seized with languor, giddiness, occasional loss of sight, deh-

numbness, tingling and coldness of the extremities, so that she could hardly walk. The pulse was quick, and respiration difficult, but she suffered no pain in any part. On the administration of an emetic, she vomited a yellowish liquid smelling strongly of camphor. In the evening the symptoms were much diminished, but she had slight convulsive fits during the night. The next day she was convalescent; the difficulty of breathing, however, continued more or less for several weeks. This is the smallest dose of camphor which appears to have been attended with serious symptoms in an adult. It has proved fatal to infants and children, the symptoms being chiefly vomiting and purging, with violent convulsions.

A case of poisoning by camphor would be recognized by the odor of the breath, a symptom which would attract the attention of a non-professional person. The presence of this substance in the stomach would be at once indicated by its odor.

LEVANT NUT. (COCCULUS INDICUS.)

Symptoms and effects.—This is the fruit or berry of the ANAMIRTA COCCULUS (*Levant Nut*), imported from the East Indies. The berry contains from one to two per cent. of a poisonous principle (*Picrotoxine*). The shell or husk contains no picrotoxine but a non-poisonous principle called *menispermine* (see Fig. 28). The seeds, in powder or decoction, give rise to nausea, vomiting, and griping pains, followed by stupor and intoxication. There are, so far as I am aware, only two well-authenticated instances of this substance having proved fatal to man. Several men suffered from this poison in 1829, near Liverpool; each had a glass of rum strongly impregnated with cocculus indicus. One died that evening; the rest recovered. (Traill's "Outlines," 146.) Of the second case, the following details have been published: A boy, æt. 12, was persuaded by his companions to swallow two scruples of the composition used for poisoning fish. It contained cocculus indicus. In a few minutes he perceived an unpleasant taste, with burning pain in the gullet and stomach, not relieved by frequent vomiting—as well as pain extending over the whole of the abdomen. In spite of treatment, a violent attack of gastroenteritis supervened, and there was much febrile excitement, followed by delirium and purging, under which the patient sank on the nineteenth day after taking the poison. On inspection, the vessels of the pia mater were congested with dark-colored liquid blood. There was serous effusion in the ventricles of the brain, and the right lung was congested. In the abdomen there were all the marks of peritonitis in an advanced stage. The stomach was discolored, and its coats were thinner and softer than natural. (Canstatt, "Jahresbericht," 1844, 5, 298.) Porter, ale, and beer, owe their intoxicating properties in some instances to a decoction, or extract, of these berries. For some remarks on this adultera-

tion of beer and other liquids, and a process for separating the poisonous principle, *picrotaxine*, by amylic alcohol, see "Chemical News," March 12, 1864, p. 123. *Cocculus indicus* operates readily as a poison on animals, and it has thus been frequently used for the malicious destruction of fish and game. In one instance referred to me, there was reason to believe that two hundred and seventy young pheasants had been poisoned by grain soaked in a decoction of this substance. *Barber's poisoned wheat*, for the destruction of birds, owes its poisonous properties to *cocculus indicus*. (Horsley.) *Picrotaxine* has a remarkably bitter taste. (See "Poisons," 3d ed. p. 679.) [Several cases of accidental poisoning by this substance are recorded by the late Dr. Fish, of Philadelphia, witnessed by himself in the Philadelphia Hospital. Some of them proved fatal in half an hour, the patient dying in convulsions. (Wharton and Stillé, Med. Jurisp., 1873, ii. p. 596)—R.]

POISONOUS MUSHROOMS (FUNGI).

Symptoms and effects.—The noxious species of mushrooms act sometimes as narcotics, and on other occasions as irritants. It would appear from the reports of several cases, that when the narcotic symptoms are excited, they come on soon after the meal at which the mushrooms have been eaten, and they are chiefly manifested by drowsiness, giddiness, dimness of sight, and debility. The person appears as if intoxicated, and there are sometimes singular illusions of sense. The pupils are dilated. Spasms and convulsions have been occasionally witnessed among the symptoms, chiefly in fatal cases. In some instances these have been of a tetanic character with great difficulty of breathing. ("Brit. Med. Jour.," Oct. 10, 1874.) When the drowsiness passes off, there is generally nausea and vomiting; but sometimes vomiting and purging precede the stupor. If the symptoms do not occur until many hours after the meal, they partake more of the characters of irritation, indicated by pain and swelling of the abdomen, vomiting, and purging. In a recent case of poisoning by mushrooms, there was slight vomiting about an hour and a half after the meal, but no violent symptoms until after the lapse of ten hours. Several cases, in which the symptoms did not appear for fourteen hours, are reported in the "Medical Gazette" (vol. 25, p. 110). In some instances the symptoms of poisoning have not commenced until thirty hours after the meal; and in these, narcotism followed the symptoms of irritation. It might be supposed that these variable effects were due to different properties in the mushrooms; but the same fungi have acted on members of the same family, in one case like irritants, and in another like narcotics. In most cases recovery takes place, especially if there is early vomiting. In the instances which have proved fatal, there has been greater or less inflammation of the stomach and bowels, with congestion of the vessels of the brain. (See "Med. Gaz.," vol. 46, p. 307; vol. 47, p. 673; and "Journ. de Chimie Méd.," 1853, p. 694.)

Poisoning with mushrooms is usually the result of accident or mistake. They are not taken for the purpose of suicide, and I have met with only one instance in which it was alleged they were intentionally given to

destroy life. In August, 1873, a gardener in the metropolitan district was committed on a charge of murder for causing the death of a young woman by giving her poisonous mushrooms. The accused, it was alleged, had a motive for the act, but he denied that he knew the mushrooms to be poisonous. The deceased fried them, and had some for breakfast. She suffered severe pain, and died the same evening. Other persons who partook of them were also taken ill, but recovered.

This form of homicide would be very difficult to establish. It would be necessary to show that the mushrooms were really poisonous, and to the knowledge of the accused. None might be forthcoming, so that there would be no botanical evidence of their poisonous nature. But as persons have died from taking edible mushrooms (see case, *infra*), it might be alleged that there was nothing criminal in the act, and that the death was owing to idiosyncrasy.

In the "Guy's Hospital Reports" for October, 1865, p. 382, I have recorded two fatal cases, in a mother and daughter, who died from the effects of the *Amanita citrina*, a yellow-colored fungus, gathered in mistake for mushrooms. The woman fried the fungi, and they were eaten for supper. No symptoms appeared for seven hours. The child when seen by a medical man was feverish and thirsty, and the pupils were strongly dilated. There was severe pain in the stomach, and a sense of constriction in the throat. The child became convulsed and insensible, and died forty-one hours after eating the fungi. The mother and another child suffered from similar symptoms; the mother partially recovered, but had a relapse, and died on the fifth day. No inspection of the bodies was made.

These fungi can be recognized only by their special botanical characters. An experienced mycologist (the Rev. J. Berkeley) says: "No general rule can be given for the determination of the question whether fungi are or are not poisonous. Color is quite indecisive, and some of the most dangerous fungi, and amongst them the *Agaricus Phalloides*, are void of any unpleasant smell when fresh, though the most wholesome may be extremely offensive when old. Experience is the only safe test, and no one should try species incautiously with whose character he is not thoroughly acquainted." The learned mycologist who gives this advice, appears to have forgotten that a person may lose his life in making this "thorough acquaintance" with the characters of fungi. Portions of the fungi may be found in the food or in the contents of the stomach; but if there have been vomiting and purging, it is probable that the whole of the substance will be expelled. Fungi contain but little solid matter.

Much has been said and written on the methods of distinguishing the edible from the noxious fungi, but instances have occurred in which the former have produced symptoms of poisoning, and have destroyed life. A case in which a woman died in twenty hours from eating ordinary mushrooms was communicated to me by Dr. H. P. Smith, of Shepton Mallet, in August, 1873. The symptoms resembled those above described.

HENBANE. (*HYOSCYAMUS NIGER*.)

Symptoms and appearances.—The seeds, roots, and leaves of this plant are poisonous. When the dose is not sufficient to destroy life, the

Fig. 29.

Seeds of henbane.

a. Natural size.

b. Magnified 30 diameters.

symptoms are: General excitement, fulness of the pulse, flushing of the face, weight in the head, giddiness, loss of power, and tremulous motion of the limbs, somnolency, dilatation of the pupils, double vision, nausea, and vomiting. After a time these symptoms pass off, leaving the patient merely languid. When a large quantity of the *root* or *leaves* has been eaten—an accident which has occurred from the plant having been mistaken for other vegetables—more serious effects are manifested. In addition to the above symptoms in an aggravated form, there will be loss or incoherency of speech, delirium, confusion of thought, insensibility, coma, and sometimes a state resembling insanity; the pupils are dilated and insensible to light, there is coldness of the surface, cold perspiration, loss of power in the legs, alternating with tetanic rigidity and convulsive movements of the muscles, the pulse small, frequent, and irregular, the respiration deep and laborious. (See “Med. Gaz.,” vol. 47, p. 640.) Occasionally there is nausea, with vomiting and purging. Death may take place in a few hours or days, according to the severity of the symptoms.

The special effect of this poisonous plant is manifested in its tendency to produce a general paralysis of the nervous system. It owes its properties to the presence of an alkaloid (*Hyoscyamia*). According to Mr. White, the biennial is more powerful than the annual plant. This gentleman reports the case of a woman, aged thirty-four, who swallowed, by mistake for a black draught, an ounce and a half of the tincture of hyoscyamus. Symptoms came on in ten minutes; the most marked among them being a complete loss of power to move her legs; insensibility and delirium followed, and it was six days before she began to recover. She entirely lost her memory. (“Lancet,” July 5, 1873, p. 8.)

Analysis.—When the vegetable has been eaten, it can be identified only by its botanical characters. The seeds are very small and hard; they are furrowed on the surface, and may be easily confounded with those of belladonna. They are of an oblong, oval, or pyriform shape. The leaves are peculiar in shape and other characters, by which they may be easily identified. *Hyoscyamia* is very difficult of extraction. The crystals have a silky lustre; they are not very soluble in water, but are easily dissolved by alcohol and ether. It has an alkaline reaction, and its saline solutions are precipitated by tannic acid. It has an acrid disagreeable taste, resembling that of tobacco. It is highly poisonous, and causes dilatation of the pupils.

(SPINAL POISONS.)

CHAPTER XIX.

NUX VOMICA.—STRYCHNIA.—SYMPTOMS AND APPEARANCES.—CHEMICAL AND MICROSCOPICAL ANALYSIS OF NUX VOMICA AND STRYCHNIA.—PROCESS FOR ORGANIC MIXTURES.—BRUCIA.

NUX VOMICA. STRYCHNIA.

NUX VOMICA in powder has a bitter taste, and cannot therefore be easily administered in a poisonous dose without exciting suspicion. It owes its poisonous properties to the presence of from one to one-half per cent. of the alkaloid *strychnia*, associated with another alkaloid named *brucia*. Strychnia itself has a very bitter taste, even in very small quantity; but as it destroys life in a small dose, and it may be given in the form of pills, or professedly administered as quinine or other medicines, it offers every facility for criminal administration.

Symptoms.—At a variable interval after taking either nux vomica or strychnia in a poisonous dose, the person experiences a sense of uneasiness and restlessness, accompanied by a feeling of impending suffocation. There is a shuddering or a trembling of the whole frame, with twitchings and jerkings of the head and limbs. Tetanic convulsions then commence suddenly with great violence, and nearly all the muscles of the body are simultaneously affected. The limbs are stretched out involuntarily, the hands are clenched; the head after some convulsive jerkings is bent backwards, and the whole of the body becomes as stiff as a board. As the convulsions increase in frequency and severity, the body assumes a bow-like form (*opisthotonos*), being arched in the back and resting on the head and heels. The head is firmly bent backwards, and the soles of the feet are incurvated or arched, and everted, the legs sometimes separated. The abdomen is hard and tense, and the chest spasmodically fixed, so that respiration appears to be arrested. The face assumes a dusky, livid or congested appearance, with a drawn, wild or anxious aspect, the eyeballs are prominent and staring, and the lips are livid. The intellect is clear, and the sufferings, during this violent spasm of the voluntary muscles, are severe. The patient in vain seeks for relief in gasping for air and in requiring to be turned over, moved or held. The muscles of the lower jaw, which are the first to be affected in tetanus from disease, are generally the last to be affected by this poison. The jaw is always fixed during a paroxysm. The patient can frequently speak and swallow, and great thirst has been observed among the symptoms. In some cases of poisoning by nux vomica, the jaw has been fixed by muscular spasm; but, unlike the lock-jaw of disease, this has come on suddenly in full intensity with tetanic spasms in other muscles,

and there have been intermissions which are not witnessed in the tetanus of disease. The sudden and universal convulsion affecting the voluntary muscles has sometimes been so violent that the patient has been jerked off the bed. After an interval of half a minute to one or two minutes, the convulsions subside, there is an intermission, the patient feels exhausted, and is sometimes bathed in perspiration. It has been noticed in some of these cases that the pupils during the paroxysm are dilated, while in the intermission they are contracted. The pulse during the spasms is so quick that it can scarcely be counted. Slight causes, such as an attempt to move, a sudden noise, or gently touching the patient, will frequently bring on a recurrence of the convulsions. In cases likely to prove fatal, they rapidly succeed each other and increase in severity and duration until at length the patient dies utterly exhausted. The tetanic symptoms produced by strychnia, when once clearly established, progress rapidly either to death or recovery. The person is conscious, and the mind is commonly clear to the last. He has a strong apprehension of death. The duration of the case, when the symptoms have set in, is reckoned by minutes, while in the tetanus of disease, when fatal, it is reckoned by hours, days, and even weeks. As a general statement of the course of these cases of poisoning, within two hours from the commencement of the symptoms the person either dies or recovers, according to the severity of the paroxysms and the strength of his constitution. Death sometimes takes place in a paroxysm. (See case by Mr. Lawrence, "*Lancet*," June, 1861, p. 572.) In strychnia poisoning the temperature of the body is much increased.

The time at which the symptoms commence appears from the recorded cases to be subject to great variation. In poisoning by *nux vomica*, the symptoms are generally more slow in appearing than in poisoning by strychnia. Until they set in suddenly, the patient is capable of walking, talking, and going through his or her usual occupations. In a case which occurred to M. Pellarin, a man swallowed about 300 grains of *nux vomica* and no symptoms appeared for two hours. He died speedily in a violent convulsive fit. ("*Ann. d'Hyg.*," 1861, vol. 2, p. 431.) On an average in poisoning by strychnia, the symptoms appear in from five to twenty minutes. The longest interval recorded was in the following case: A boy, æt. 12, swallowed a pill containing three grains of strychnia. No symptoms appeared for *three hours*; they then set in, in the usual way, and death took place in ten minutes. It was clearly proved that the pills taken had been composed of three grains of strychnia with mucilage; they had been prepared eight months previously for the purpose of poisoning dogs; hence they were hard, and underwent only slow solution in the body. ("*Lancet*," 1861, 2, 480.)

The form in which the poison is administered or applied has a considerable influence on the time at which the symptoms commence. Thus when strychnia is given in pills, especially if, as in the above case, they are hard, the symptoms are much longer in appearing than when the poison is taken in solution.

Appearances after death.---In general the body is relaxed at the time of death, and stiffens afterwards; but the commencement and duration of the rigid state depend on various conditions.

Among the *internal* appearances which have been met with in different cases, are congestion of the membranes and substance of the brain, as also of the upper part of the spinal marrow, with congestion of the lungs. The heart is contracted and empty; but its right cavities in some instances are full of liquid blood. The blood has been found black and liquid throughout the body. The mucous membrane of the stomach has occasionally presented slight patches of ecchymosis or congestion, probably depending on extraneous causes,—such as the process of digestion, the presence of food, or of alcoholic liquids. In most instances, the stomach and intestines have been found quite healthy, and it is not in the nature of this poison to either inflame or irritate the mucous membrane. Of the appearances observed in poisoning by strychnia, there are none which can be considered strictly characteristic. Congestion of the membranes of the brain and spinal marrow is probably the most common.

Fatal dose.—The *sixteenth part of a grain* of strychnia killed a child between two and three years of age in four hours. The smallest fatal dose in an adult was in the case of *Dr. Warner*. *Half a grain* of the sulphate of strychnia here destroyed life. (“On Poisoning by Strychnia,” pp. 138, 139.) So powerful are the effects of this drug in certain cases that ordinary medicinal doses can scarcely be borne. Symptoms of its poisonous action have frequently been unexpectedly produced. *Dr. Fraser* states that its action is most powerful through the skin. He found that when applied to rabbits hypodermically, from one-twentieth to one-fiftieth of a grain produced violent tetanic convulsions, followed, in a few minutes, by death.

With respect to *nux vomica*, three grains of the alcoholic extract have destroyed life. The smallest fatal dose of *nux vomica* in powder was in a case reported by Hoffmann, and quoted by Christison (p. 901), also by Traill (“*Outlines*,” p. 137). *Thirty grains* of the powder, given in two doses of fifteen grains each, proved fatal. The poison was given by mistake for bark to a patient laboring under quartan fever. This is about equivalent to the weight of one full-sized seed, and to only one-third of a grain of strychnia in the two doses.

In fatal cases death generally takes place within two hours after the taking of strychnia. One of the most rapidly fatal cases recorded is that of *Dr. Warner*. The symptoms commenced in five minutes, and he died in *twenty minutes*. In the case of *J. P. Cook*, the symptoms commenced in an hour and a quarter, and terminated fatally in *twenty minutes*. In poisoning by *nux vomica*, death may occur within two hours. Sir R. Christison mentions a case in which a man died in *fifteen minutes* after taking a dose. This is probably the shortest period known.

Vermin and Insect Killers.—Although it is difficult to procure strychnia at a druggist’s shop, the poison is extensively sold to the public, in threepenny and sixpenny packets, under the name of Vermin Killers. *Butler’s Vermin Killer* consists of a mixture of flour, soot, and strychnia. I have found the sixpenny packet to weigh about a drachm, and to contain from two to three grains of strychnia. As the poison is mechanically mixed with the other ingredients (flour and coloring matter), and is probably manufactured on a large scale, the propor-

tion of strychnia is liable to variation. The threepenny packet contains about half the quantity of strychnia, but this is quite sufficient to destroy the life of an adult. In place of soot, Prussian blue is sometimes used as a coloring substance. *Battle's Vermin Killer* is a powder similar to that of Butler, containing a fatal proportion of strychnia, as it is sold in packets. These powders are a fertile source of poisoning, either through accident or design; they are openly sold by ignorant people to others still more ignorant.

Chemical analysis.—*Nux vomica* is well known as a flat, round kernel, about the size of a shilling, with radiating silken fibres, slightly raised in the centre. It is of a light brown color, and covered with fine silky fibres. (See Figs. 30 and 31.) It is very hard, brittle, tough, and difficult to pulverize. The powder is of a gray brown color, like

Fig. 30.

Fig. 31.

that of liquorice; it is sometimes met with in a coarsely rasped state; it has an intensely bitter taste. It yields to water and alcohol, strychnia, brucia, igasuric or strychnic acid, and some common vegetable principles. Heated on platinum foil, it burns with a yellow smoky flame. Nitric acid turns it of a dark orange-red color, which is destroyed by chloride of tin. These chemical properties are sufficient to distinguish it from various medicinal powders which it resembles in color; but the presence of any silky hairs or fibres, revealed by the microscope (Fig. 32), would at once distinguish it from all other powders. They may be obtained from the contents of the stomach or any liquid article of food by washing and decantation. They are quite insoluble in water. The aqueous infusion or decoction of *nux vomica* is deeply reddened by nitric acid, and is freely precipitated by tincture of galls. Persulphate of iron gives with it an olive-green tint.

Strychnia.—This alkaloid may be readily obtained crystallized from an alcoholic solution. The crystal is very small, and its form is subject to great variation, according to the strength of the solution, rapidity or slowness of evaporation, the presence of foreign matters, etc. It is commonly seen in octahedra, sometimes lengthened into prisms of a peculiar shape, bevelled at the ends, and crossing each other at angles of 60° . (See Fig. 33.) There are as many as six or eight varieties of crystals, so that too much importance must not be attached to this branch of the analysis. As strychnia is procured from the solutions of its salts by

the addition of ammonia, it is usually deposited in long slender prisms. (Fig. 34.)

Fig. 33.

Various forms of crystals of strychnia, as they were obtained from an alcoholic solution. Magnified 124 diameters.

Fig. 34.

Crystals of strychnia obtained by adding ammonia to the sulphate. Magnified 124 diameters.

1. Strychnia is white, of an intensely bitter taste, even when it forms only 1-30,000th part of a watery solution. 2. When heated on platinum, it melts and burns like a resin, with a black smoky flame; in a close tube it yields ammonia. 3. It is not perceptibly dissolved by cold water; it requires 7000 parts for its solution. 4. It is easily dissolved by acids, and it is precipitated from its concentrated solutions by potash, in which it is insoluble. 5. Strong nitric acid imparts to it a pale red-dish color, owing to the presence of brucia. 6. Sulphuric acid produces no apparent change in it; but when to this mixture a small crystal of bichromate of potash, of ferricyanide of potassium, or a small quantity of black oxide of manganese, or of peroxide of lead, is added, a series of beautiful colors (blue, purple, and violet) appear, passing rapidly to a light red tint (green with bichromate). Among these substances black oxide of manganese will be found preferable for use.

Mr. Horsley has suggested that a solution of strychnia should be sufficiently concentrated, and then precipitated by chromate of potash; the crystals may be examined microscopically; they are seen to form gradually in tufts of radiated prisms of a yellow color (Fig. 35.) On being touched with strong sulphuric acid, the color reactions of strychnia are at once brought out. Pieric or carbazotic acid, recommended by Dr. Guy, is even a more delicate precipitant of a solution of strychnia. It gives small tufts or groups of stellated crystals.

Strychnia has been fatally mistaken for *santonine* ("Lancet," 1870, 1, 598), *salicine*, and *jalapine*, and has caused death on several occasions. *Jalapine* does not crystallize; and the crystalline forms of *santonine* and *salicine* are very different from those of strychnia. These two vegetable principles

Fig. 35.

Crystals of chromate of strychnia, magnified 124 diameters.

differ from strychnia in their properties. When heated in close tubes, they give off acid vapors. Salicine is soluble in water. Santonine is not soluble in water, but is dissolved by alcohol. Tannic acid and the chloriodide of potassium and mercury do not precipitate the solutions, while they readily precipitate those of strychnia. Nitric acid has no effect upon either, while sulphuric acid, which does not change santonine, gives a pink red color to salicine. Chloride of gold is a delicate precipitant of strychnia. According to M. Filhol, 1-650th part of a grain is thus thrown down in a crystalline state. This precipitate, collected and dried, may be dissolved in concentrated sulphuric acid, and any of the color tests then applied to it. Iodic acid is not decomposed by strychnia or its salts, and sulpho-molybdic acid gives to it slowly, only a pale blue color. It is thus readily distinguished from morphia. In testing solutions of strychnia the presence of alcohol should be avoided.

In *Organic mixtures* a modification of the process originally suggested by Stas may be employed for the separation of this poison. The principle of its operation consists in dissolving the strychnia by a gentle heat out of the tissue or organ, very finely cut up, by means of rectified spirit mixed with a small quantity of acetic acid. The liquid is strained, and the residue well pressed and washed with alcohol; the acid solution of strychnia thus obtained is concentrated in a water-bath. The concentrated liquid is carefully neutralized by potash or its bicarbonate, a slight excess of alkali being added. The alkalinized liquid is then shaken in a long stoppered tube, with twice its volume of ether, or a mixture consisting of two parts of ether and one of chloroform. These liquids dissolve the strychnia set free by the alkali. The ethereal solution is separated from the watery liquid by a pipette, and submitted to spontaneous evaporation, when, if strychnia is present, the alkaloid will be obtained, but generally associated with oily and other organic matters, which may interfere with the production of crystals. The impure residue left by the ether is heated in a water-bath, with a few drops of strong sulphuric acid: this destroys the organic matter. Water is added, and the acid liquid is filtered through paper, neutralized by potash, and again treated with ether, when strychnia will be obtained in small and slender prisms. The crystals, after an examination by the microscope (see Fig. 34, p. 233) are treated with sulphuric acid and peroxide of manganese, and the color-reactions of strychnia, if the alkaloid is present, will appear. Mr. Bloxam has recommended the use of benzole in place of ether; while the process of separating strychnia by dialysis (p. 103) has been most successfully carried out by Dr. Gray, of Glasgow. The reader will find in his essay on strychnia a full account of the method of employing this process for the detection of the poison in organic liquids and the best modes of applying the tests. ("Strychnia," by Dr. James St. Clair Gray, Glasgow, 1872, p. 75.) Whatever process may be adopted, the analyst should bear in mind that it is better to operate on a small quantity of strychnia in a pure state than on a large quantity in an impure state.

Non-detection of strychnia in the body.—Strychnia does not appear to undergo any change in the dead body from the process of putrefaction, but it may disappear from the stomach like opium or morphia, and owing to similar causes (see p. 205). In the case of *Reg. v. Pearson* (Durham

Summer Ass., July, 1875), where death was clearly traced to strychnia, only the 1-16th part of a grain was found in the body by Dr. Scattergood. Had the man survived a few hours longer, probably none would have been found. Dr. C. Cameron, of Dublin, informs me that in the case of a man who died from strychnia, administered by his stepmother, not a trace of the poison could be detected through the entire viscera. It is well known that in the case of Cook (*Reg. v. Palmer*, 1856) the chemical evidence failed to show that any strychnia remained in the body, and some chemical experts at this trial maintained that unless strychnia were found in the body death could not be ascribed to this poison. In Cook's case the prisoner Palmer, who was present at the post-mortem, cut through the stomach and mixed the contents with the whole of the intestines and their contents. Under these adverse circumstances Dr. Rees and I could not find very satisfactory evidence of the presence of strychnia in the large quantity of organic and fecal matter with which the contents of the stomach had been mixed. The non-detection here appeared to be sufficiently explained except by those who claim infallibility in analysis.

A trial involving a similar question was tried recently at the Assizes in Bavaria. A veterinary surgeon was charged with the murder of his wife by strychnia. The body was exhumed after four months' burial, and analysis of the viscera was made by Professor Büchner of Munich, but with a purely negative result. No trace of strychnia could be detected in the body. ("Ann. d'Hyg.," March, 1880, p. 279.) Profs. Dragendorff, of Dorpat, and Uslar, of Göttingen, were called on the part of the defence, and they deposed in the most positive manner that strychnia could always be found in the body of a person poisoned by the alkaloid even after four months' burial. After this categorical statement the court ordered the prisoner to be discharged. There was probably in this case an absence of supplementary evidence. In the case of W. Palmer the deficiencies of the chemical evidence were supplied by proofs from symptoms and post-mortem appearances, as well as by proof of possession of the poison and administration by the prisoner. In a case of poisoning by this alkaloid, which was the subject of a trial for murder at Perry Co., Penna., in April, 1861, Dr. Reese, of Philadelphia, made separate analyses of the contents of the stomach and the contents of the intestines, as well as of the tissues, and each one of these was repeated to avoid all possible error. Yet there was no evidence of the presence of strychnia by the bitter taste of the final extract, or by the color tests. The witness, by a comparative experiment, satisfied himself that he could detect the half-millionth of a grain ("Amer. Journ. Med. Sci.," Oct. 1861), but in this power of detecting so small a quantity of strychnia in a pure state he had already been anticipated by Mr. W. Copney ("Pharm. Journ.," July, 1856, p. 24). In Dr. Reese's case, the quantity taken was unknown, the woman lived five or six hours, and the body was not examined until six weeks after death. A small but fatal dose, and the duration of the case will sufficiently account for the negative results, without resorting to any other hypothesis. In the case of *Mrs. Salter*, who died from a dose of strychnia in September, 1869, death probably took place within two or three hours, but the most

careful examination made of the stomach and liver by Mr. Horsley, of Cheltenham, led to a negative result. Strychnia, in the opinion of all the medical witnesses was the cause of death, but no trace of strychnia could be detected in the body by one well qualified to detect it. There was some reason to think that the poison had been taken in solution, but even under these circumstances it must have been rapidly absorbed, diffused, and eliminated. Strychnia has been detected in the liver and other viscera of the body, even after putrefaction had set in. It has also been found in the blood. [See paper by the Editor "On the Influence of Morphia in Disguising the Color-test of Strychnia;" also "On the Comparative Bitterness of Strychnia," and "On the Physiological or Frog-test for Strychnia," in the "Am. Journ. of Med. Sci.," Oct. 1861.—R.] This question is now in a great measure set at rest. A person may die from poison, although none may be detected in the body. Among recent cases that of *Chantrelle* may be quoted as an illustration.

When the poison has been taken in the form of *nux vomica* it is rare that it can be discovered in the absorbed state in the tissues, as the seed contains only about one per cent. of the alkaloid strychnia. In the case of an infant which died in three hours from a dose of *nux vomica*, absorbed strychnia was sought for in the different organs, but none could be detected, although there was no doubt that it had been the cause of death. In poisoning with *nux vomica*, brucia will be more readily detected than strychnia.

Brucia.—Brucia is an alkaloid generally associated with strychnia in the seeds of *nux vomica*, but it is more abundantly contained in the bark of the tree. It is not so powerful a poison as strychnia, but the symptoms which it produces are similar. It is considered to have about one-sixth of the strength of strychnia. It is not affected by the color-tests employed for the detection of strychnia, and it acquires an intense red color on the addition of nitric acid. [This is changed to violet by the action of chloride of tin.—R.] It is much more soluble in water than strychnia, and has a bitter taste. Its aqueous solution is strongly alkaline, and by spontaneous evaporation, it yields groups of slender prismatic crystals arranged in a fan-like shape. Unlike strychnia, it cannot be

crystallized from a solution in benzole, and only imperfectly from a solution in alcohol. Hydrochloric and iodic acids produce in it no change, either in the cold or when heated. Sulphuric acid gives to it a pink red color without carbonizing it. The sulphate of brucia crystallizes in well-defined prisms truncated at the ends. They are larger and longer than the prisms of strychnia. (See Fig. 36.) From a case of poisoning with this alkaloid which occurred to Dr. Edwards, it is necessary to give a caution to medical men respecting the possible criminal use of brucia. The symptoms which it causes, so closely resemble those of poisoning with

Fig. 36.

Crystals of sulphate of brucia, magnified 124 diameters.

strychnia, that in the event of death, the latter poison only may be sought for and not found. The real poison, brucia, may be overlooked. The tetanic symptoms are more slowly produced by brucia, and the poison is not so rapidly fatal as strychnia; but these conditions may be altered by the larger quantity given.

When, in any suspected case, the color-tests for strychnia fail to show the presence of this alkaloid, nitric acid should be added to the crystalline residue obtained (as in the process for strychnia) from ether or chloroformic ether. The intense reddening produced by this test, with the other characters above mentioned, will indicate the presence of brucia. Sulphomolybdic acid (p. 234) also forms a striking distinction between the two alkaloids. While it slowly gives a pale blue with strychnia, it rapidly gives a deep brick-red color, passing to brown-red, with brucia or its salts.

(CEREBRO-SPINAL POISONS.)

CHAPTER XX.

CONIUM MACULATUM.—HEMLOCK.—CONIA.—ÆNANTHE CROCATÆ.—ÆTHUSA CYNAPIUM.—ACONITE OR MONKSHOOD.—ACONITINA.

COMMON OR SPOTTED HEMLOCK. (CONIUM MACULATUM.) CONIA.

Symptoms and appearances.—The effects produced by hemlock have not been uniform: in some instances there have been stupor, coma, and slight convulsions; while in other cases the action of the poison has been chiefly manifested on the spinal marrow—*i. e.*, it has produced paralysis of the muscular system. A man ate a large quantity of hemlock-plant, by mistake for parsley. In from fifteen to twenty minutes there was loss of power in the lower extremities; but he apparently suffered no pain. In walking, he staggered as if he was drunk; at length his limbs refused to support him, and he fell. On being raised, his legs dragged after him, and when his arms were lifted they fell like inert masses, and remained immovable. There was perfect paralysis of the upper and lower extremities within two hours after he had taken the poison. There was loss of power of swallowing, and a partial paralysis of sensation, but no convulsions, only slight occasional motions of the left leg; the pupils were fixed. Three hours after eating the hemlock, the respiratory movements had ceased. Death took place in three hours and a quarter; it was evidently caused by gradual asphyxia from paralysis of the muscles of respiration; but the intellect was perfectly clear until shortly before death. On inspection, there was slight serous effusion beneath the arachnoid membrane. The substance of the brain was soft; on section there were numerous bloody points, but the organ was otherwise healthy. The lungs were gorged with dark fluid blood; the heart was soft and flabby. The stomach contained a green-colored pulpy mass resembling parsley. The mucous coat was much congested, especially at its greater end.

Here there were numerous extravasations of dark blood below the membrane, over a space of about the size of the hand. The intestines were healthy, here and there presenting patches of congestion in the mucous coat. The blood throughout the body was fluid and of a dark color.

In a case which was the subject of a trial for murder (*Reg. v. Bowyer*, Ipswich Summer Assizes, 1848), a child died in one hour after swallowing part of a teacupful of a decoction of hemlock, alleged to have been administered by the mother. The child sipped the decoction, until it lost the power of holding the cup; it became insensible and paralyzed, and died in the chair in a sitting posture. There were no morbid appearances, and no hemlock leaves were found in the body, these having subsided in the cup, and being left in the dregs. The child had been poisoned by the upper stratum of clear liquid. The mother was acquitted for want of proof, the death of the child having taken place in secrecy.

Hemlock is known from most other plants which resemble it by its large round smooth stem, with dark purple spots. The leaves are of a dark green color, and smooth and shining. Every portion of the plant has a peculiar and disagreeable smell when bruised, resembling cat's urine, or, according to some, the odor of mice. It is strongly brought out when the stem, leaves, or seeds are rubbed with a solution of caustic potash. An illustration of the seeds of hemlock, is annexed (Fig. 37). They are peculiar in their form, and are easily distinguished from the seeds of other umbelliferous plants. A person may be poisoned by a decoction of leaves of hemlock, and no leaves be found in the stomach or bowels (case of *Bowyer*, supra). In this case the stomach had been emptied, and the contents lost, before it was sent to me! No trace of conia was found.

Fig. 37.

- a Seed of hemlock, natural size.
- b The same, magnified 30 diameters.
- c Group of seeds.

The poisonous alkaloid of hemlock is known under the names of *conia*, *concin*, *conicine*, and *conicina*. It resembles nicotine and ammonia in

its liquidity, volatile reaction, and in some of its chemical properties. It is a liquid of oily consistency, of a pale yellow color, powerfully alkaline, and has, when its vapor is diluted, a smell resembling that of mice, and an acrid bitter taste. It gives a volatile greasy stain to paper, and burns with a yellow flame and thick smoke. 1. It is not colored or affected by nitric, sulphuric, or hydrochloric acid; the last-mentioned acid produces with it, dense white fumes of hydrochlorate of conia, and on heating the mixture, this salt remains in prismatic crystals. [Prof. Wormley states ("Micro-chemistry of Poisons," p. 449) that when strong sulphuric acid is brought into contact with pure conine, the mixture assumes a pale red color, which increases in intensity, and after a time becomes nearly blood-red. The action of nitric and sulphuric acids is nearly similar, especially that of the former.—R.] 2. It is not dissolved by water, but floats on it in oily globules. It is soluble in alcohol and ether, and this last-mentioned liquid removes it from its aqueous solution, and leaves it in oily globules on evaporation. In reference to

its presence in *organic mixtures*, it may be detected by its peculiar odor, or by distilling the liquid with a solution of potash, and examining the distillate.

The reaction produced by tests on small quantities should be distrusted, unless there is strong evidence of the action of the poison on the body from the symptoms. As in reference to strychnia, veratria, and other alkaloids, an incautious operator may readily come to the conclusion that he has found "traces," and ascribe death to the poison. The following case occurred in Germany a few years since. A man died very suddenly, *i. e.*, in two hours and a half after going to bed, and it was alleged that his wife had poisoned him. The persons commissioned to make the analysis deposed that they had found traces of conia in the stomach, intestines and kidneys, and they came to the conclusion that the man had died from the effects of hemlock, which implicated his wife in the charge of murder. Some doubt appears to have arisen in the minds of the authorities on this point, and the matter was then referred to Mitscherlich and Casper, of Berlin, and they found that the chemical processes pursued failed to detect conia in the body—that there was nothing to indicate that deceased had taken hemlock or conia in any form, and that the state of the windpipe sufficiently accounted for the sudden death of deceased. He had eaten and drunk freely, had vomited after going to bed; a portion of the food had entered the trachea and had suffocated him. (See Casper's "Vierteljahrschrift," 1859, p. 194.)

WATER-HEMLOCK. (*CICUTA VIROSA*.)

Synptoms and appearances.—The symptoms produced by the roots of this plant are giddiness, dimness of sight, headache, and difficulty of breathing. There is burning pain in the stomach, with vomiting, and these symptoms are accompanied by heat and dryness of the throat. Convulsions have been observed to precede death. In the case of three children who died in convulsions from this poison, Metzдорff found an injected state of the mucous membrane of the stomach, with redness of the air-passages, as well as of the cardia, and pylorus; the vessels of the brain and sinuses were filled with dark liquid blood. (Wibmer, "Cicuta," 119.)

HEMLOCK WATER-DROPWORT. (*ÆNANTHE CROCATA*.)

This umbelliferous plant grows on the banks of rivers, streams, and ditches. It is one of the most poisonous of the order, and is considered to be one of the most virulent of English vegetable poisons.

Synptoms and appearances.—In April, 1857, two cases of poisoning with this plant occurred at West Boldon, in Durham. Two laborers ate some of the roots of the *ænanthe*. They were found soon afterwards lying insensible and speechless, their faces livid, tongues swollen and protruded, and there were convulsive movements of the jaws, with frothy mucus and blood about their mouths, the eyes full and projecting, pupils dilated, breathing stertorous and labored, with occasional general convulsions. They both died in an hour and a half from the time at which

they were first discovered. On inspection, it was found that there had been bleeding from the ears; the abdomen was livid and swollen. The stomach contained a gruelly liquid with some of the partly digested roots; on removing this liquid, the lining membrane was found congested and softened. The lungs were engorged with dark liquid blood, and the blood contained in the heart was in a similar state. Mr. Boyle, to whom these cases occurred, forwarded to me a portion of the roots, and there was no doubt that they were the roots of the *cenanthe crocata*. I am indebted to Mr. Drinkwater, of Llangollen, for an account of three cases of poisoning by this plant, in April, 1875, two of which proved fatal. It seems that three boys ate the roots and stems of the plant, which they supposed to be wild carrots. They had a sweet, nutty taste. One boy complained of feeling cold, and was attacked with severe vomiting and purging. After this he recovered, and was able to give evidence at the inquest on his two companions. A second boy was found dead in the road about fifty yards from the brook where the *cenanthe* grew. He had vomited, and had struggled, being violently convulsed. His face was black, and froth had escaped from his mouth. The third boy was found in a similar condition—dead, with froth about his mouth. The post-mortem examination revealed congestion of the brain with black fluid blood, engorgement of the lungs and heart with the same, congestion of the mucous membrane of the stomach. This organ contained the masticated root of the *cenanthe*, with some of the green leaves. (For other cases see "Medical Gazette," vol. 34, p. 288.) This plant is equally fatal to animals. Dr. Cameron states that forty-three oxen which were turned into a pasture in which the *cenanthe* grew were killed by eating the plant. Foaming at the mouth, shivering, difficult breathing, and tetanic spasms, with pleuro-thotonos or spasmodic bending of the body to one side, were among the symptoms. ("Lancet," June 28, 1873, p. 918.)

It is not often that attempts are made to destroy others by the administration of these vegetable poisons; but a case occurred in France in which a woman attempted to poison her husband by mixing slices of the root of this plant with his soup. His suspicions were excited by the acrid taste of the soup. The woman was tried for the crime, and M. Toulmouche deposed at the trial that the plant from which the root had been taken was the *cenanthe crocata*, that it was a powerful poison, and might cause death in two or three hours. The prisoner was convicted, and condemned to ten years at the galleys. ("Gaz. Med.," Jan. 3, 1846, 18; also, "Journ. de Chim. Med.," 1854, 533.)

Analysis.—The *cenanthe crocata* can be identified only by its botanical characters. The leaves are of a dark green color, with a reddish-colored border. They have no unpleasant odor when rubbed. The seeds, of which an illustration is annexed (Fig. 38), are peculiar. The plant bears a greater resemblance to celery than most of the other umbelliferæ. Its stem is channelled, round, smooth, and branched, of a yellowish-red color, and growing to the height of two or three feet. The root consists of a series of oblong tubercles, with long slender fibres. It is of a yellowish-white color, and not unpleasant to the taste. It is the most active part of the plant. The leaves yield much tannic acid to water, but the decoction appears to contain no alkaloidal base,

Fig. 38.

Seeds of *ananthe crocata*. d. Natural size. b. Magnified 30 diameters. c. One half of a seed magnified. e. One half natural size. e. Group of seeds.

since the chloriodide of potassium and mercury produces no precipitate in it. The roots and stems of this plant are more frequently eaten than the leaves or seeds.

FOOL'S PARSLEY. (*ÆTHUSA CYNAPIUM*.)

FOOL'S PARSLEY, OR LESSER HEMLOCK, is very common in gardens and hedge-rows. The leaves so closely resemble those of parsley that they have often been gathered for them by mistake.

Symptoms and appearances.—In May, 1845, a girl, æt. five years, in good health, ate the bulbs of the *æthusa* by mistake for young turnips. She was suddenly seized with pain in the abdomen, followed by a feeling of sickness; but she did not vomit. She complained of feeling very ill. On trying to eat she could not swallow. She was incapable of answering questions, and her countenance bore a wild expression. The lower jaw became fixed, so as to prevent anything being introduced into the mouth. She then became insensible, and died in *an hour* from the commencement of the symptoms; so far as could be ascertained, there were no convulsions. A second child, æt. three years, shortly after eating the same substance, was attacked with pain in the stomach, sickness, vomiting, and profuse perspiration. She soon recovered, with the exception of suffering severe griping pains without purging; but these disappeared on the following day. A third child, of the same age, suffered from similar symptoms. Recovery in the last two cases was probably due to the plant having been eaten on a full stomach, and to the effect of early and copious vomiting. ("Med. Times," Aug. 23, 1845, 408.)

This plant is known from garden parsley by the smell of its leaves when rubbed, which is peculiar, disagreeable, and very different from that possessed by the leaves of parsley. The leaves of fool's parsley are finer, more acute, and of a darker green color. The seeds are also peculiar. They are represented in the annexed illustration (Fig. 39). Its flower-stem, which is striated or slightly grooved, is easily known from all other unbelliferous

Fig. 39.

a. Natural size.
b. Magnified 30 diameters.
c. Group of seeds.

plants by the beard, or three long pendulous leaves of the involucre under the flower. The flowers are white; those of the garden parsley are of a pale yellow color. Dr. Harley denies the poisonous properties of this plant. (See "ON POISONS," 3d ed. p. 745.)

MONKSHOOD. (ACONITUM NAPELLUS.) ACONITINA.

This well-known garden plant is in some parts of the country called *Wolfsbane*, and in Ireland *Blue-rocket*. The roots, seeds, and leaves are highly poisonous, owing to the presence of the alkaloid *aconitina*; the root is especially noxious, and when the leaves have fallen off, it appears to possess its greatest virulence. These parts of the plant, when masticated, produce a peculiarly cool numbing sensation, affecting the lips, tongue, and interior of the mouth generally. At first the root appears to be tasteless, as the effects are only strongly manifested after a quarter of an hour or twenty minutes. From tasting only a small portion of the dried root, I found that this disagreeable sensation remained on the tongue and lips for four hours. In larger quantity the taste has been described as burning, and it is stated to have been followed by a hot acrid sensation in the throat.

Symptoms and appearances.—In from a few minutes to an hour after the poison has been taken, the patient complains of numbness and tingling in the mouth and throat, which are parched: there is giddiness, with numbness and tingling in the limbs, a loss of power in the legs, sometimes frothing at the mouth, and severe pain in the abdomen, followed by vomiting and purging. In some cases the patient is completely paralyzed, but retains his consciousness: in others the giddiness is followed by dimness of sight, delirium, and other cerebral symptoms, but not amounting to the complete coma produced by the cerebral or narcotic poisons. The pupils are dilated, the pulse sinks, the skin is cold and livid, and the breathing difficult. Convulsions are not commonly observed in man; they are indicated by general tremors or twitchings of the voluntary muscles. The poison produces convulsions in animals. Poisoning by the *root* of aconite is by no means unfrequent. In the spring or autumn, the root is liable to be mistaken for that of horseradish. It has been thus accidentally eaten on several occasions, and has caused death. A mistake of this kind led to fatal results in three hours in a case which occurred at Lambeth; and another set of cases occurred at Dingwall, in Scotland, in January, 1856. Here three persons were poisoned by reason of their having had sauce made with the root of aconite, served at dinner with roast beef in place of horseradish sauce! They were healthy adults; they all died within three hours and a half. These mistakes show deplorable ignorance, but there is always the risk of their occurrence when horseradish and aconite are grown near to each other in a garden, at that season of the year when the leaves have fallen.

The tincture of the *root* is a powerful poison. In January, 1853, a woman took by mistake *seventy minims* of *Fleming's tincture* of the root mixed with one grain of acetate of morphia. In a few minutes she became very thirsty, complained of a burning sensation and pain in her

stomach, to relieve which she swallowed a quantity of cold water. In fifteen minutes there was violent vomiting, which continued for two hours. She lost the power of standing, and was very restless. The pain in the stomach increased, and there were convulsive movements of the muscles. She was conscious until shortly before her death, which took place in about four hours after she had taken the poison. There were no general convulsions: the pain in the stomach was well marked throughout. On inspection, the membranes of the brain were congested, but the brain itself was firm and healthy. The lungs were healthy; and the heart was flaccid, the uterus congested. The stomach contained some mucus, and the lining membrane at the larger curvature was injected (reddened) in patches, but otherwise natural. The mucous membrane of the duodenum was in a high state of inflammation, partially abraded, softened, and broken down. Some spots were of a very dark color, passing into

Fig. 40.

Root of aconite.

Fig. 41.

Root of horseradish.

mortification. In October, 1852, an excise officer lost his life by merely tasting Fleming's tincture of aconite, under the supposition that it was flavored spirit. He was able to walk from the custom house over London bridge, but he died in about four hours after tasting the poison.

The case of the man *Hunt*, who, in November, 1863, destroyed his wife and children by prussic acid, and himself by aconite, presents some features of interest in reference to the symptoms and appearances produced by the *tincture*. The quantity taken by him was not determined; but the man was soon afterwards seized with violent spasmodic retching, face pale, skin cold and clammy, pulse small and hardly perceptible, and the action of the heart feeble. The pupils were much dilated, and the eyes brilliant and sparkling; the breathing was quiet and regular, except during the fits. He complained of pain in his heart. In attempting to walk, he staggered, and had no power to raise his arms. He was perfectly conscious, called for writing materials, and wrote a few lines. He then became suddenly worse, and a quarter of an hour before his death he lost all power and sensation in his limbs, the sharpest pinches producing no impression. The pulse was imperceptible. There were no convulsions, but complete relaxation of the limbs at death, which appeared to arise from syncope three-quarters of an hour after he had taken the poison. On *inspection*, forty-two hours after death, there was great rigidity of the muscles. The substance of the brain was firm and healthy: the vessels on the surface were filled with blood. The heart was healthy: the right side was greatly distended with dark fluid blood: the left side contracted and quite empty. The lungs were healthy. In the abdomen the viscera were healthy, with the exception of the stomach and duodenum. There was great capillary congestion at the larger end of the stomach, the mucous membrane having a bright red color. There were marks of irritation, with softening and separation of the mucous lining, the whole of the membrane being in a highly corrugated condition. Traces of aconitina were found in the contents of the stomach. The deceased had provided himself with an ounce of the tincture of aconite, and had swallowed the greater part of this mixed with water.

Analysis.—The botanical characters of the leaves and root, when any portions can be obtained, will enable a medical witness to identify this vegetable poison. The root has been frequently and fatally mistaken for horseradish, but there are these striking differences: 1. Aconite root is very short, conical, and tapers rapidly to a point (Fig. 40). 2. It is externally of an earthy-brown color, internally white, and of an earthy smell; the cut surface is rapidly reddened by exposure to air. It has numerous long thin fibres proceeding from it. 3. It has at first a

bitter taste, but after a quarter of an hour or twenty minutes it produces a disagreeable sense of tingling and numbness on the lips and tongue. 1. Horseradish root is long, cylindrical, or nearly so, and of the same thickness for many inches (Fig. 41). 2. It is externally whitish-yellow, and has a pungent odor when scraped. 3. Its taste is sometimes bitter, but it produces an immediate hot or pungent sensation.

The leaves of aconite or monkshood are of a dark-green color and of a peculiar shape. When masticated they slowly produce on the

Fig. 42.

a. Seed of aconite, natural size.
b. The same magnified 30 diameters.

lips and tongue the persistent sense of tingling and numbness, with the sense of coolness observed in the root. They are less powerful than the root and seeds. The seeds are dark-colored and differ in appearance from those of other poisonous plants (Fig. 42).

Aconitina.—The alkaloidal base of this plant, *aconitina*, is a formidable poison, exceeding all others in its effects. In one case one-fiftieth part of a grain nearly proved fatal to an elderly lady (Pereira, "Mat. Med.," vol. 2, pt. 2, p. 695); and it is probable that *one-tenth* part of a grain of pure *aconitina* would prove fatal to a human being. Some samples of this alkaloid are, however, much less potent than others, and the chemical properties are different. (See paper by Schroff, "Reil's Journal für Toxikologie," 3d H. 1857, p. 335, and one by Liégeois, "Chem. News," Oct. 24, 1863, p. 201.) The latter contains the account of a simple method for the extraction of the alkaloid.

A sample of English *aconitina* possessed the following properties: It was in whitish granular masses, without any distinctly crystalline structure. 1. When heated it readily fused and burnt in the air with a bright yellow flame. 2. Heated in a close tube, it evolved first an alkaline and then an acid vapor. 3. It was scarcely soluble in water, but was dissolved by weak acids and alcohol: it did not readily crystallize. 4. Nitric acid dissolved it, without causing any change of color. 5. Sulphuric acid gave to it a yellowish color, and green oxide of chromium was separated on adding to it a crystal of bichromate of potash. *Aconitina* cannot be separated from its solutions in a crystalline state by the addition of ammonia. 6. Tannic acid and the chloriodide of potassium and mercury readily precipitated the solution.

Aconitina is sufficiently soluble in ether to allow of its separation from *organic liquids* by a process similar to that used for strychnia (p. 234). Dr. Headland recommends, as a physiological test, the production of an alcoholic extract of the contents of the stomach, and its application to animals. One-twentieth of a grain will be sufficient: the 1-300th of a grain will poison a mouse; the 1-100th, a bird; and 1-1000th cause stinging and numbness of the tip of the tongue. The 1-100th of a grain dissolved in spirit and rubbed into the skin, causes loss of feeling, lasting for some time. ("Lancet," March 29, 1856, p. 343.) There is, however, a great difference in the properties of this alkaloid, according to the mode in which it has been prepared (Bouchardat, "Ann. de Thérapeutique, 1864, pp. 48 and 54; also "Annuaire," 1863, p. 41).

CHAPTER XXI.

ATROPA BELLADONNA, OR DEADLY NIGHTSHADE.—POISONING BY ATROPIA.
—LOBELIA.—DATURA STRAMONIUM, OR THORNAPPLE.—DATURIA.

DEADLY NIGHTSHADE. (ATROPA BELLADONNA.) ATROPIA.

Symptoms.—The symptoms which are produced by the leaves, berries, seeds, and root of belladonna are of a uniform character, and, as a summary, they may be thus described: Heat and dryness of the mouth and throat, nausea, vomiting, giddiness, indistinct or double vision, delirium, great excitement, convulsions, followed by stupor and lethargy. The pupils are much dilated, and the eyes are insensible to light. In two cases which occurred to Mr. Tufnell, the pupils were contracted during sleep, although dilated in the waking state. (“Dublin Med. Press,” Jan. 5, 1853; “Journal de Chimie Médicale,” 1853, p. 695.) Several deaths from the poisonous effects of the *berries* occurred in London in 1846. The following case was admitted into Guy’s Hospital: A boy, æt. 14, ate, soon after breakfast, about thirty of the berries of the belladonna, which he had bought as fruit in the streets. In about three hours he had the sensation of his face being swollen: his throat became hot and dry, his vision was impaired, objects appeared double, and they seemed to revolve and run backwards. His hands and face were flushed, and his eyelids swollen; there were occasional flashes of light before his eyes. He tried to eat, but could not swallow on account of the state of his throat. In endeavoring to walk home he stumbled and staggered; and he felt giddy whenever he attempted to raise his head. His parents thought him intoxicated: he was incoherent—frequently counting his money, and did not know the silver from the copper coin. His eyes had a fixed, brilliant, and dazzling gaze; he could neither hear nor speak plainly, and there was great thirst; he caught at imaginary objects in the air, and seemed to have lost all knowledge of distance. His fingers were in constant motion: there was headache, but neither vomiting nor purging. He did not reach the hospital until nine hours had elapsed; and the symptoms were much the same as those above described. He attempted to get out of bed with a reeling, drunken motion; his speech was thick and indistinct. The pupils were so strongly dilated that there was merely a ring of iris, and the eyes were quite insensible to light. The eyelids did not close when the hand was passed suddenly before them. He had evidently lost the power of vision; although he stared fixedly at objects as if he saw them. The nerves of common sensation were unaffected. When placed on his legs he could not stand. His pulse was 90, feeble, and compressible; his mouth was in constant motion, as if he were eating something. His bladder was full of urine on admission. He con-

tinued in this state for two days, being occasionally conscious, when by a free evacuation of the bowels, some small seeds were passed; these were examined and identified as the seeds of belladonna. The boy gradually recovered, and left the hospital on the sixth day after his admission: the progress of recovery was indicated by the state of the pupils, which had then only acquired their natural size and power of contraction.

In three other cases which occurred at the same time, the berries having been baked in a pie, pains in the limbs, drowsiness, insensibility, and convulsions, were among the symptoms. In two instances of poisoning by the berries related by Dr. Moll, the symptoms bore a strong resemblance to those of delirium tremens, but among them were some peculiar to the action of belladonna, namely, heat and dryness of the throat, loss of power of swallowing, incoherent speech, double vision, and strange spectral illusions, with occasional fits of wild and ungovernable laughter. On the following morning both these patients recovered as if from a dream; but they suffered for some time from languor, thirst, and dryness of the throat: the pupils also continued dilated. (Casper's "Wochenschrift," 10 Jan. 1846, p. 26.) Two cases, showing the poisonous effects of the berries on children, are quoted in the "Edinburgh Medical and Surgical Journal." (Vol. 29, p. 452.) The following case, which occurred in Nov. 1871, is remarkable for the fact that a woman recovered from a large dose of the extract. A nurse gave by mistake to a lady whom she was attending a belladonna liniment containing three drachms of the extract mixed with soap liniment. She had vomited slightly. When seen by Mr. F. Keen he found her suffering from dryness of the throat, difficulty of swallowing, drowsiness, delirium, pupils dilated, fixed staring of the eyes, loss of power and difficulty of speech. Paralysis of the extremities came on, with great pain in the back. Emetics with brandy and cayenne pepper were employed with success. The woman recovered, but not until after five weeks from the time of swallowing the liniment. A child nearly four years old swallowed only two or three drops of a liniment containing belladonna. The child went to sleep for an hour, when it was seized with tremblings and convulsions, dilated pupils, delirium, and other symptoms of belladonna poisoning. It recovered only after three days, this being indicated among other signs by the normal state of the pupils. ("Guy's Hosp. Gazette," June, 1878.) In another case, in which a lady swallowed four ounces of belladonna liniment, in addition to the usual symptoms speech was lost. There was complete paralysis of the legs, and a diffused scarlet rash appeared on the neck and the upper part of the chest. She fell into a state of somnambulism, and on her recovery in three or four days, her life appeared to be a complete blank. ("Brit. Med. Jour.," Nov. 25, 1876, p. 678.)

This poison readily acts through the unbroken skin. In one case equal parts of mercurial ointment and extract of belladonna were applied to the scrotum of a man. On the second day all the symptoms of poisoning came on, with flushed face and pupils dilated and insensible to light. ("Brit. Med. Jour.," Feb. 1877, p. 164.)

Appearances.—The appearances observed in several cases of poisoning with the berries, which proved fatal in London during the autumn of

1846, were as follows: the vessels of the brain were congested with liquid blood; the stomach and intestines were pale and flaccid; there were some red spots towards the cardiac end. In other fatal cases, of which the appearances have been reported, the vessels of the brain and its membranes were found distended with thick black blood. Red spots have also been observed around the throat and gullet, and congested patches of a dark purple color on the coats of the stomach. In some instances the mucous membrane has been completely dyed by the juice of the berries. A boy, æt. 5, after having eaten a quantity of the berries of the belladonna, went to bed, was very restless, vomited once, and died in convulsions about fifteen hours after having taken the poison. On inspection, the eyes were half-open, with an intense lustre; the pupils dilated; the mouth was spasmodically closed, and the sphincter ani relaxed. The cerebral vessels were distended with dark-colored blood: the substance of the brain, cerebellum, and medulla oblongata presented numerous bloody points. In the throat and gullet there were several patches of redness. In the stomach there was some fluid, with three open berries; the mucous membrane was of a reddish-blue color in various parts. (Case by Dr. Rosenberger, Canstatt's "Jahresb.," 1854, p. 295.)

Analysis.—The indigestible nature of the leaves, fruit, and seeds will commonly lead to their detention in the matters vomited or passed by the bowels, or in the contents of the viscera after death. The seeds of belladonna are very small; they can be distinguished by the microscope from the seeds of other poisonous plants. They are of a somewhat oval shape and of a dark color. Under a low magnifying power they present a honeycombed surface (Fig. 43). In henbane the surface of the seed presents more irregular depressions resembling those seen on certain corals or madrepores. The coloring matter of the berry is of a deep purple hue; it is turned green by alkalis, and red by acids. The leaves would be known by their botanical characters, and a decoction or infusion of them by the liquid causing dilatation of the pupil.

Seeds of belladonna.

b. Magnified 30 diameters.

Atropia.—Atropia is the name given to the alkaloidal principle of belladonna; it is a powerful poison. Some consider it to be identical with daturia, the poisonous alkaloid of thornapple, but this is not yet satisfactorily established, either chemically or physiologically. Symptoms of poisoning have been produced by the application of a weak solution of atropia to the eyes. Dr. Bowles found about one-sixtieth of a grain repeated twice in half an hour, making one-thirtieth of a grain, dropped into the eye, produced in two adults, after some hours, loss of vision, giddiness, soreness of the throat, loss of power of swallowing, and widely dilated pupils. The latter symptom remained for eight days. ("Brit. Med. Jour.," April, 1876, p. 533.) One-eighth of a grain injected beneath the skin for the relief of sciatica, caused all the symptoms of poisoning with belladonna. One grain used endermically nearly proved fatal at Guy's Hospital, and in the following case reported by Mr. Leach ("Med. Times and Gaz.," July 6, 1865, p. 34), a man

who swallowed, by mistake, a grain of sulphate of atropia in solution, had a narrow escape of his life. In an hour afterwards, the following symptoms were observed: the pupils were enormously dilated, so that the irides were scarcely visible; the eyes moved restlessly from side to side. The pulse was very quick, and the patient appeared as if intoxicated. In another hour his hands were cold, the pulse weak, and there was loss of power in the limbs. He became restless, incoherent, and unconscious of preceding events. There was also delirium. In a later stage there was morbid sensitiveness to sounds and objects; the tongue was furred, and the skin dry and hot. The pupils continued dilated for a week, and for several days there was a partial paralysis of the bladder. He recovered in a fortnight.

A fatal case of poisoning by sulphate of atropia is recorded by Dr. Greenway. A man, æt. forty-five, swallowed by mistake, a teaspoonful of liquor atropiæ sulphatis, equal to half a grain of the sulphate. The usual symptoms of poisoning followed, but it is remarkable that the patient did not die until the sixth day. ("Brit. Med. Jour.," Oct. 5, 1878, p. 516.)

Analysis.—Atropia is a white crystalline substance, not very soluble in water, but easily dissolved by alcohol, ether, and diluted acids. It does not readily crystallize, but it forms crystallizable salts. The crystals melt at 194° , and at 284° they are volatilized; being at the same time in great part decomposed. Ammonia added to a solution of sulphate of atropia does not separate the alkaloid in distinct crystals. In this respect it differs from morphia and strychnia. When atropia is heated on platinum it melts, darkens in color, and burns with a yellowish smoky flame. Sulphuric, hydrochloric, and nitric acids dissolve it without any change of color. It does not decompose iodic acid. Sulphomolybdic acid produces in it no change; but after a time the mixture acquires a light blue color. When to the mixture with sulphuric acid, a crystal of bichromate of potash is added, a green color is produced by the formation of oxide of chromium. Tannic acid precipitates the alkaloid from its solutions; but the most effectual precipitant is the chloriodide of potassium and mercury, which throws down a dense white precipitate even in very diluted solutions. Atropia is also precipitated by chloride of gold, but, unlike strychnia, it is not precipitated by sulphocyanide or chromate of potassium. It may be detected in, and separated from, organic liquids by the process of Stas. (See p. 234.)

According to Winckler, atropia is precipitated most completely from all its solutions by the chloriodide of potassium and mercury. By the use of this precipitant he was able to determine the proportion of atropia contained in the powder of the dry leaves and root. In the leaves the alkaloid varies from 0.41 to 0.49 per cent., and in the root it amounts to 0.48 per cent. ("Pharm. Journ.," June, 1872, p. 1029.) [According to Wormley ("Micro-chem. of Poisons," p. 630), the most characteristic test for atropia is a solution of bromine in hydrobromic acid; this reagent produces, even in highly diluted solutions of atropia, a yellow amorphous precipitate, which shortly becomes crystalline.—R.]

There are no absolute or certain chemical tests for this alkaloid when contained in an organic liquid. The only test usually employed is of a

physiological nature, namely, the effect produced on the pupil by small quantities of liquid, or extract, containing traces of atropia. The pupil is largely dilated, and the eye loses its sensibility to light. *Daturia*, *hyoscyamia*, and *digitaline* also produce dilatation of the pupil. Poisonous mushrooms and other noxious organic matters have a similar effect, so that there is nothing conclusive in this result, unless there is also strong evidence from *symptoms* that *belladonna* has been actually taken or administered.

At the Exeter Autumn Assizes for 1865 (*Reg. v. Sprague*), a medical man was charged with attempting to poison his wife and other persons with atropia, which, it was alleged, had been placed in a rabbit pie. The evidence failed to show at the trial that the prisoner, or any other person, could have mixed poison with the pie, much less such a poison as this, which in the dose of one or two grains either destroys life or produces serious illness continuing for some time. The symptoms, as described, resembled those caused by noxious food, and differed in many respects from those of poisoning by atropia. The only fact on which this chemical theory seemed to rest, was that the pupils of the eyes of those who ate of the pie and were taken ill, were dilated, and a portion of the extract of the scrapings of the pie dish is said to have caused a dilatation of the pupil of the analyst. (See "*Med. Times and Gaz.*," August 12, 1865, p. 168; also "*Chemical News*," August 11, 1865, p. 72.) It is stated that the supposed poison was separated from the baked leg of a rabbit by soaking it in dilute hydrochloric acid, but, according to those who have examined the properties of atropia, this alkaloid melts at 194° , is entirely volatile under 300° , and is then in great part decomposed. This is below an ordinary cooking temperature. ("*Chemie der Organischen Alkalien*, Schwartzkopf," p. 317.) The whole of the scientific theory rested upon the dilatation of the pupils, and this, although presumptive, is not positive evidence of atropia having been administered.

The criminal administration of atropia is a rare event in this country. A trial for murder by this alkaloid took place at the Manchester Lent Assizes, 1872 (*Reg. v. Steele*). The prisoner, who was a nurse in the workhouse, was charged with administering atropia to the senior surgeon, Mr. Harris, and thereby causing his death. The deceased was taken suddenly ill after his breakfast, and died under the usual symptoms of poisoning with atropia in about twelve hours. The poison was detected in the body by Mr. Calvert, and also in a liquid found in the room—a solution of atropia in spirit. Milk was the vehicle through which it was taken. The milk as sent from the kitchen contained nothing injurious, but that found in deceased's room was tasted by two of the nurses and both suffered from poisoning by atropia. The prisoner had access to this room, and it was alleged that she had a strong motive for this criminal act, but there was no direct proof to show that she put the poison into the milk, and she was acquitted.

INDIAN TOBACCO. (LOBELIA INFLATA.) LOBELINA.

The powdered leaves of Indian tobacco contain an acrid principle, *lobelina*, which is capable of producing poisonous effects on the brain and spinal marrow, attended with irritation of the stomach and bowels. When administered in doses of from ten to twenty grains, lobelia operates as an emetic; but in larger quantity it acts deleteriously. In one case a man lost his life by swallowing *one drachm* of the powdered *leaves*, prescribed by a quack. This person was seen by a medical practitioner soon after he had taken the poison: he was evidently suffering great pain, but he was quite unconscious,—the pulse was small, and the pupils were strongly contracted and insensible to light. He had vomited the greater part of the poison. He suffered from spasmodic twitching of the face, sank into a state of complete insensibility, and died in about thirty-six hours. On inspection, some fluid was found in the stomach, but none of the powder. The mucous membrane was intensely inflamed, and the vessels of the brain were strongly congested. ("Pharm. Times," May 1, 1847, p. 182.) The *seeds* of lobelia are equally poisonous. In the "Med. Times and Gazette," Nov. 26, 1853, p. 568, two cases are reported in which the seeds proved fatal. In one, the mucous membrane of the stomach was highly inflamed. Another case is referred to in the same journal, March 12, 1853, p. 270. There have been many inquests and trials for manslaughter in this country as the result of the improper administration of the leaves of the *Lobelia inflata* by ignorant quacks, calling themselves medical botanists and dealers in vegetable medicines. The medical evidence given on these trials has proved that in large doses lobelia is a most noxious drug.

Lobelia is seen in the form of a greenish-colored powder (fragments of leaves). This powder acquires a reddish-brown color from strong nitric acid, and is blackened by concentrated sulphuric acid. Iodine water has no effect upon the infusion. The proto- and persulphate of iron produce with it a dark-green color—the per-sulphate very rapidly. The leaves and seeds contain a resinoid substance called *lobelina*, which has the smell and taste of the plant. It acts as a powerful emetic in doses of from one-half to one grain. The leaves of lobelia are generally seen in fragments which do not readily admit of identification by the microscope. The *seeds* are very small, of a lengthened oval shape (Fig. 44), reticulated on the surface with projecting hairs or fibres, and of a light brown color. The discovery of them among the fragments of leaves would furnish a sufficient proof of the presence of lobelia.

Seeds of lobelia.
a. Natural size.
b. Magnified 70 diameters.

THORNAPPLE. (DATURA STRAMONIUM.) DATURIA.

Symptoms and appearances.—The symptoms produced by stramonium, whether the leaves or seeds are used, are as follows: soon after the poison

has been taken there are giddiness, dimness of sight, a sense of fainting, insensibility, fixed and dilated pupils, flushed countenance, and a slow and full pulse. Sometimes there is great restlessness, with a hot and red skin, and a wild and staring expression in the countenance, the breathing hurried and gasping, incessant talking without distinct articulation; and there are attempts to drive away, or grasp at, imaginary objects. There is picking at the bedclothes, with paroxysms of excessive laughter; and if the person can walk, it is with a staggering gait, and he falls to the ground as if intoxicated, or completely exhausted. The seeds of two varieties of datura were used by the Thugs of India for rendering their victims powerless and insensible.

Appearances.—In a well-marked case of poisoning by stramonium-seeds, in which death took place in less than eight hours, the following appearances were found: great congestion of the vessels of the brain and its membranes, the brain firm and highly injected, choroid plexus turgid, ventricles containing serum, substance of the lungs congested, and the heart flaccid. The stomach contained about four ounces of digested food, mixed with eighty-nine seeds of stramonium. There were two patches of extravasation in the mucous coat—one on the larger curvature, and the other near the pylorus. Many seeds and fragments were also found in the intestines. ("Lancet," Sept. 18, 1847, p. 298.) In another case there were marks of diffused inflammation about the cardiac end of the stomach.

Analysis.—The seeds of stramonium, from which accidents have most frequently occurred, are flattened, kidney-shaped, but half-oval, rough, and of a dark-brown or black color. They are liable to be mistaken for the seeds of capsicum. Of the dry datura stramonium, there are about eight seeds to a grain. They are of an oblong kidney-shape, and of a dark-brown or black color. The illustration (Fig. 45) shows their appearance under a low power of the microscope. The leaves of the common datura stramonium are well characterized by their peculiar shape.

Fig. 45.

Seeds of datura stramonium.
a. Natural size.
b. Magnified 30 diameters.

Fig. 46.

Crystals of datura, magnified 30 diameters.

Datura.—The poisonous properties of thornapple are owing to the presence of an alkaloid, *datura*, which forms about one per cent. of the dried vegetable. Some have considered this alkaloid to be identical

with atropia, but the physiological properties are different. See Bouchardat, "Ann. de Thérapeutique," 1864, p. 24. [Prof. Wormley believes these two alkaloids to be identical in both their physiological and chemical properties. The bromine test answers equally well for each.—R.] Daturia crystallizes in long colorless prisms or needles (Fig. 46); it has a bitter taste, somewhat acrid, and slightly resembling that of tobacco. It is poisonous. The eighth of a grain killed a sparrow in three hours. When placed on the eye, or introduced into the cellular membrane of an animal, it is observed, like atropia, to cause dilatation of the pupil. When heated in a tube it is decomposed, and ammonia is evolved, as with other alkaloids. It is soluble in water, and the solution has an alkaline reaction. It is precipitated by *tannic* acid and by the chloriodide of potassium and mercury. Nitric and hydrochloric acids dissolve it without producing any change of color. Sulphuric acid produces with the crystals a pale rose-red color, which becomes paler when the acid mixture is diluted with water. Stramonium is sometimes smoked like tobacco, but daturia has not been found in the smoke.

(CEREBRO-CARDIAC POISONS.)

CHAPTER XXII.

TOBACCO.—NICOTINA.—FOXGLOVE, OR DIGITALIS.—DIGITALINE.—OTHER POISONOUS SUBSTANCES.

TOBACCO. (NICOTIANA TABACUM.) NICOTINA.

Symptoms.—The effects which tobacco produces, when taken in a large dose, either in the form of powder or infusion, are well marked. The symptoms are faintness, nausea, vomiting, giddiness, delirium, loss of power in the limbs, general relaxation of the muscular system, trembling, complete prostration of strength, coldness of the surface, with cold clammy perspiration, convulsive movements, paralysis, and death. In some cases there is purging, with violent pain in the abdomen: in others, there is rather a sense of sinking or depression in the region of the heart, passing into syncope, or creating a feeling of impending dissolution. With the above-mentioned symptoms there is dilatation of the pupils, with insensibility to light, dimness of sight, with confusion of ideas, a small, weak, and scarcely perceptible pulse, difficulty of breathing, and involuntary discharge of urine.

Tobacco operates as a poison when applied externally. A remarkable instance of this kind is reported in the "Lancet" (March, 1879, p. 296). A woman, æt. 40, suffering from varicose veins, struck her leg accidentally against a sewing machine. Severe hemorrhage followed, and to stop this she applied some tobacco to the wounds, and bandaged the leg. Three-quarters of an hour afterwards she consulted Dr. O'Neill about the bleeding, and the symptoms which she then presented were alarming.

She had fainted in the interval, but had recovered after taking some brandy and water, but she said she then felt as if she were dying. Dr. O'Neill found her quite prostrated, with the skin pale, cold, and wet with a clammy perspiration. The pupils of the eyes were much dilated, and in a faint whisper she complained of dimness of sight, dizziness, and confusion of thoughts. There was severe pain in the abdomen, with constant nausea and vomiting.

As these symptoms were not explained by the accident to the leg, Dr. O'Neill removed the bandage, and he then found that a handful of chopped tobacco had been applied firmly to the wounds, which were deeply stained by it. This was the first intimation which he had of the use of tobacco, and it fully accounted for the unusual symptoms. The tobacco was removed, the skin well cleansed, stimulants were given, and the woman then completely recovered from the effects of the poison. This case illustrates the action of the poison by absorption through the bloodvessels.

Nicotina.—Tobacco owes its poisonous properties to the presence of a liquid volatile alkaloid, *Nicotina*. This is a deadly poison, and like prussic acid it destroys life in small doses with great rapidity. It has the powerful odor of tobacco. It is volatile, and may be procured by distillation. I found that a rabbit was killed by a single drop in three minutes and a half. ("Guy's Hospital Reports," Oct. 1858, p. 355.) A case of poisoning by this alkaloid which occurred in Belgium in 1851, was the subject of a trial for murder case of the *Count Beurné*. ("Ann. d'Hyg.," 1851, vol. 2, pp. 147 and 167.) In another, which proved fatal in from three to five minutes, the appearances observed were a general relaxation of the muscles, prominent and staring eyes, bloated features, great fulness with lividity about the skin of the neck. There was no odor resembling nicotina or tobacco perceptible about the body. When the body was examined between two and three days after death, putrefaction had occurred. The swelling of the neck was found to arise from an effusion of dark liquid blood, especially in the course of the veins. The scalp and the membranes of the brain were filled with dark-colored blood. The lungs were engorged, and of a dark purple color. The cavities of the heart were empty, with the exception of the left auricle, which contained two drachms of dark-colored blood. The stomach contained a chocolate-colored fluid, in which nicotina was detected: the mucous membrane was of a dark crimson-red color from the most intense congestion. There was no odor excepting that of putrefaction. The liver was congested, and of a purple-black color. The blood throughout the body was black and liquid, but in some parts it had the consistency of treacle. (G. H. R., Oct. 1858, p. 354.) The insidious nature of this poison is proved by the fact that in September, 1877, a child, *æt.* 3 years, died from using an old wooden pipe for blowing soap-bubbles. It had been used by his father for smoking, but had been put by for a year. He had washed it before giving it to his son. The child was quite well at the time, but in an hour he was seized with drowsiness and sickness, and died with all the symptoms of narcotic poisoning. He had imbibed sufficient nicotina from the pipe to destroy life.

Nicotina is presep in some segars in the proportion of about four

per cent., but the smoke derived from them contains none. Small quantities of sulphide and cyanide of ammonium were found in the smoke. Snuff yielded from .04 to .06 per cent. of nicotina. ("Ann. d'Hyg.," 1873, 1, p. 436.)

FOXGLOVE. (DIGITALIS PURPUREA.) DIGITALINE.

Symptoms and effects.—Cases of poisoning with foxglove are not very common. A boy who swallowed six ounces of a strong decoction of the leaves was soon attacked with vomiting, purging, and severe pain in the abdomen. After some time he became lethargic, and slept for several hours; in the night he was seized with convulsions. The pupils were dilated and insensible, the pulse was slow, small, and irregular; coma followed, and the boy died twenty-two hours after taking the poison. On inspection, the membranes of the brain were found much injected, and the mucous lining of the stomach was partially inflamed. The prisoner was acquitted of the charge, because he had only given his fatal advice on the application of the friends of the deceased! ("Ed. Med. and Surg. Jour.," 27, 223.) A young man swallowed a strong decoction of foxglove by mistake for purgative medicine. He was soon seized with vomiting, pain in the abdomen, and purging. In the afternoon he fell asleep. At midnight he awoke, was attacked with violent sickness, colic, and convulsions; the pupils were dilated and insensible to light; the pulse was slow and irregular. He died twenty-two hours after taking the poison. (Wibmer, op. cit., *Digitalis*.) A few grains of the powdered leaves have been known to produce giddiness, languor, dimness of sight, and other nervous symptoms. A drachm has, however, been taken without causing death; but in this instance it produced violent vomiting. A common effect of this poison is to produce great depression of the heart's action.

When foxglove has been taken in substance, *i. e.*, in the form of seeds or leaves, or any portion of these has been swallowed in a decoction or infusion, fragments may be found in the stomach and bowels. In reference to the infusion, decoction, tincture, or extract, except there be sufficient to allow of the separation of digitaline, there is no chemical process known by which the poison may be recognized. If any fragments of leaves or seeds are found in the contents of the stomach or in food, they may be identified by the aid of the microscope. The annexed illustration (Fig. 47) represents the seeds of foxglove: they are of a reddish-brown color, remarkably small, oblong, and somewhat angular in shape. They have peculiar markings. By the aid of the microscope, they may be easily distinguished from the seeds of hyoscyamus, datura, belladonna, and most other poisonous plants.

Digitaline is the active principle of foxglove. It constitutes one per cent. of the dried leaves. Its physiological properties have been fully investigated by M. Homolle. ("Journal de Pharmacie," Janvier, 1845-57;

also, by Bouchardat, "Ann. de Thérapeutique," 1864, p. 155.) It is an uncrystallizable substance, and has no well-defined chemical characters.

Pure digitaline itself operates as a poison on man and animals in very small doses. The one-sixteenth of a grain, which is considered to be equal to eight grains of the well-prepared powder of the dried leaves, is sufficient to cause symptoms of poisoning. Doses of from one-eleventh to one-thirty-second part of a grain have lowered the pulse and caused nausea, vomiting, griping, purging, and an increased secretion of urine. (Pereira, "Mat. Med.," vol. 2, p. 528.) Doses of from one-quarter to one-half of a grain would probably prove fatal to life. Digitaline has acquired some notoriety by reason of the trial of *Dr. De la Pommerais*, at Paris, in May, 1864, for the murder of a woman named *Pauw*. (See "On Poisons," 3d ed., p. 801; "Ann. d'Hygiène," 1864, tom. 2, p. 105.)

The bark, seeds, berries, and leaves of the *Laburnum*, *Yew*, and *Privet*, *Holly* and *Guelder Rose* have in a few cases given rise to symptoms of poisoning. These poisons affect the brain and the alimentary canal, producing vomiting and purging, followed by insensibility and convulsions. Accidents from these plants are not frequent, and when they occur there is usually sufficient botanical evidence of the nature of the poison taken.

WOUNDS AND PERSONAL INJURIES.

CHAPTER XXIII.

DEFINITION OF A WOUND.—DANGER TO LIFE.—GRIEVOUS BODILY HARM.—EXAMINATION OF WOUNDS.—DESCRIPTION OF WOUNDS.—CHARACTERS OF WOUNDS INFLICTED ON THE LIVING AND DEAD BODY.—ECCHYMOSIS IN THE LIVING AND DEAD.—EFFECTS OF VIOLENCE ON THE DEAD BODY.—ECCHYMOSIS NOT ALWAYS A RESULT OF VIOLENCE.

Definition.—In a medico-legal sense, a wound implies a breach of continuity in the structures of the body, whether external or internal, suddenly occasioned by mechanical violence. This definition therefore includes injuries to the skin or mucous membrane of the outlets of the body, also dislocations and fractures, whether simple or compound, as well as ruptures of the viscera. In a medical point of view, a wound is commonly restricted to those *external* injuries in which the skin is implicated; but in legal medicine the term has a much wider signification.

Danger to life.—When a wound has been criminally inflicted on a person by the wilful act of another, one of the first questions which presents itself for consideration is how far the injury is dangerous to life. In order to justify the detention of the accused, a magistrate may require a medical opinion or a written statement from the surgeon in attendance. The meaning of the words "*dangerous to life*," is left entirely to the professional knowledge of a witness. It is not sufficient on these occasions that he should make a naked declaration of the wound being dangerous to life; he must, if called upon, state to the court satisfactory reasons for his opinion; and these reasons are rigorously inquired into by counsel for the defence. As a general principle it would not be proper to consider those wounds dangerous to life, in which the danger is not *imminent*. A wound of a great bloodvessel, of any of the viscera, or a compound fracture with depression of the bones of the head, must in all instances be regarded as bodily injuries dangerous to life; because, in such cases the danger is imminent. Unless timely assistance be rendered, these injuries will most probably prove fatal, and, indeed, they often destroy life in spite of the best surgical treatment. When, however, the danger is remote, as in a puncture or laceration of the hand or foot, which may be followed by tetanus, or in a laceration of the scalp, which may be followed by erysipelas, or in penetrating wounds of the orbit, which may be attended by fatal inflammation of the brain or its membranes, the case is somewhat different.

Such injuries as these are not directly dangerous to life,—they are only liable to be attended with danger in certain cases, and under certain circumstances; hence the medical opinion must be qualified. The law, on these occasions, appears to contemplate the direct, and not the future or possible occurrence of danger; if the last view were adopted it is clear that the most trivial lacerations and punctures might be pronounced dangerous to life, since tetanus or erysipelas proving fatal, has been an occasional consequence of very slight injuries. A difference of opinion will often exist among medical witnesses whether a particular wound is or is not dangerous to life. Unanimity can only be expected when the judgment and experience of the witnesses are equal. The rules for forming an opinion in these cases will, perhaps, be best deduced from the results of the observations of good surgical authorities in relation to injuries of different parts of the body.

[In case of application for release on bail, the medical attendant may be called upon to testify as to the amount of danger to life involved in the injury inflicted, and must be governed in his deposition by the principles here laid down. The opinion should be qualified in every case of injury not directly dangerous to life, but only incidentally liable to fatal termination. Unless this distinction be clearly expressed, great injustice may be done in withholding a privilege which the law expressly grants in cases of trifling wounds.—H.]

Wounds causing grievous bodily harm.—A wound may not be dangerous to life, but it may have produced "*grievous bodily harm.*" This question is sometimes put, although the usual practice is to leave it to be drawn by the jury as an inference from a professional description of the injury. The words have a vague signification; but it would perhaps be difficult to substitute for them others less open to criticism. They evidently refer to a minor description of offence, and are applied commonly to those injuries which, while they do not actually place life in danger, may be attended with considerable personal inconvenience, or be in some way detrimental to the health of the wounded person. The late C. B. Pollock stated on one occasion that "*grievous bodily harm*" would reasonably apply to such an injury as would render medical treatment necessary. It is always a question for a jury whether the *intent* of the prisoner, in inflicting a wound, was or was not to produce grievous bodily harm. In some cases the nature or the situation of a wound, as well as the kind of weapon used, will at once explain the intent: so far the medical witness may assist the court by giving a plain description of the injury, as well as of the consequences with which it is usually attended. It may happen either that the wound itself is not of a serious nature, and yet the intention of a prisoner may have been to do grievous bodily harm to the wounded person, or the injury may be really serious, and yet the prisoner may not have intended to do grievous bodily harm.

On a trial for manslaughter which took place at the Central Criminal Court in April, 1873, Baron Cleasby made the following legal distinction between a simple wounding and wounding with intent to do grievous bodily harm. There was, he said, no proof as to the instrument, if any, with which the wound was inflicted. The injuries were certainly serious, and it would be for the jury to say whether they were done with the

intention to inflict grievous bodily harm. The intention, as it happened in this case, could only be inferred from the injury which really was done. Possibly the prisoner inflicted more than he really intended.

Let us suppose that the wounded person is found dead, and an examination of the body is required to be made. The most difficult part of the duty of a medical jurist now commences. Among the numerous questions which here present themselves, the first which demands examination, is whether the wound was inflicted on the body before or after death.

Examination of wounds.—In examining a wound on a dead body, it is proper to observe its situation, extent, length, breadth, depth, and direction; whether there is about it effused blood, either liquid or coagulated, and whether there is ecchymosis, *i. e.*, a livid discoloration of the skin from the effused blood. It should also be ascertained whether the surrounding parts are swollen, whether adhesive matter or pus is effused, whether the edges of the wound are gangrenous, or any foreign substances are present in it. Care must be taken that putrefaction is not mistaken for a gangrenous condition of the wound. The wound may be examined by gently introducing into it a bougie, and carrying on the dissection around this instrument, avoiding as much as possible any interference with the external appearances. The preservation of the external form will allow of a comparison being made at any future time between the edges of a wound and a weapon found on a suspected person. Of all these points *notes* should be taken, either on the spot or immediately afterwards. In the dissection, every muscle, vessel, nerve, or organ involved in the injury should be traced and described. This will enable a witness to answer many collateral questions that may unexpectedly arise during the inquiry. Another point should be especially attended to. A medical practitioner has frequently contented himself with confining his dissection to the injured part, thinking that on the trial of the accused the questions of counsel would be limited to the situation and extent of the wound only, but this is a serious mistake. If the cause of death be at all obscure, on no account should the inspection be abandoned until all the important organs and cavities of the body have been closely examined; since it may be affirmed that a natural cause of death might have existed in that organ or cavity which the medical witness had neglected to examine. It rests with the practitioner to disprove the probability thus urged by counsel, but he is now destitute of facts on which he can base an opinion—legal ingenuity will triumph, the witness will be discomfited, and the prisoner, of whose guilt there may be, morally speaking, but little doubt, will have the benefit of his inattention, and be acquitted by the jury. In the medical reports on the examination of the bodies of wounded persons, care should be taken to avoid the introduction of any remarks in the form of inferences from the facts of the case (*ante*, p. 29). The *facts* should be simply recorded, and the inferences or comments reserved for evidence at the inquest or trial. In making an inspection of the wounded body the stomach should not be overlooked. Death may have been apparently caused by violence, and yet really be due to poison, of which a portion may be found in the stomach or bowels.

Description of wounds.—It is impossible to impress too strongly on the mind of a medical witness, that in describing the wounds which he has found on the examination of a body, he should employ plain and simple language, and avoid as much as possible the use of technical or professional terms. The natural desire of a good witness is to make himself understood; but this cannot be accomplished if he clothes his ideas in language which is incomprehensible to educated men of the legal profession, and *à fortiori* to the class of men who constitute juries. There are few assizes which do not afford many illustrations of the injury done to scientific evidence, and the clear understanding of a case, by the technical language in which it is given. A medical witness should, for his own credit and for that of the profession to which he belongs, employ plain and simple language in describing a wound, as well as in giving his evidence generally. (See page 31.)

Characters of a wound inflicted during life.—If we find about a wound marks of gangrene, the effusion of adhesive or purulent matter, or if the edges are swollen and enlarged, and cicatrization has commenced, it is not only certain that the injury must have been inflicted before death, but that the person must have lived some time after it was inflicted. Marks of this description will not, however, be commonly found when death has taken place within ten or twelve hours from the infliction of the injury. A wound which proves fatal within this period of time will present throughout much the same characters. Thus, supposing it to have been *incised*, there will be traces of more or less bleeding, the blood having chiefly an arterial character, and it will be found coagulated where it has fallen on surrounding bodies. The edges of the wound are everted, and the muscular and cellular tissue around is deeply reddened by effused blood. Coagula or clots are found adhering to the wound, provided it has not been interfered with. The principal characters of a wound inflicted during life, are, then, the following: 1. Eversion of the edges owing to vital elasticity of the skin. 2. Abundant hemorrhage or bleeding, often of an arterial character, with general diffusion of blood in the surrounding parts. 3. The presence of coagula. The wound may not have involved any vessel, and there may be no appearance of bleeding, still the edges will be everted, and the muscles and skin retracted. By an observation of this kind made on the body of a newborn child (Case of *Elphick*, March, 1848), Mr. Prince was enabled to state that the child was living when it was inflicted, an opinion afterwards confirmed by the confession of the mother.

Characters of a wound made after death.—If the wound on a dead body be not made until twelve or fourteen hours have elapsed from the time of death, it cannot be easily mistaken for one produced during life. Either no blood is effused, or it is of a venous character, *i. e.*, it may have proceeded from some divided vein. The blood is commonly liquid, and does not coagulate as it falls on surrounding bodies, like that poured out of a wound in the living. The edges are soft, yielding, and destitute of elasticity; they are therefore in close approximation. The cellular and muscular tissues around are either not infiltrated with blood, or only to a very partial extent. There are no coagula within the wound. In experimenting upon amputated limbs, I have found these characters

possessed by a wound produced two or three hours after death, although they are best seen when the wound is not made until after the body has lost all its animal heat. In wounds on the dead body, divided arteries have no marks of bleeding about them, while in the living body the fatal bleeding commonly proceeds from these vessels. Hence in a wound on the living, it will be found that the surrounding vessels are empty. The chief characters of a wound after death are, therefore: 1. Abstinence of copious bleeding. 2. If there is bleeding it is exclusively venous. 3. The edges of the wound are close, not everted. 4. There is no diffusion of blood in the cellular tissue. 5. There is an absence of coagula. But it may happen that a wound has been inflicted soon after the breath has left the body, and while it was yet warm. The distinction between a wound then made and one made during life, is not so well marked as in wounds inflicted at a later period after death.

In any case in which it is doubtful whether a wound was inflicted on a living or dead body, we should be cautious in giving an opinion; since it must be remembered there are no decisive characters by which wounds of the kind referred to can be distinguished, and a medical witness is as likely to be wrong as right in selecting either hypothesis. It is a considerable step in evidence, when we are able to assert that a particular wound, found on a dead body, must have been inflicted either during life or *immediately* after death; for it can scarcely be supposed that in a case calling for criminal investigation, any one but a murderer would think of inflicting upon a body immediately after death a wound which would assuredly have produced fatal effects had the same person received it while living. So soon as such an opinion can be safely expressed by a witness, circumstantial evidence will often make up for that which may be, medically speaking, a matter of uncertainty.

Wounds or injuries unattended with hemorrhage.—The copious effusion of blood has been set down as a well-marked character of a severe wound received during life; but this observation applies chiefly to cuts and stabs. Lacerated and contused wounds of a severe kind are not usually accompanied with much bleeding, even when a large bloodvessel is implicated. It is well known that a whole member has been torn from the living body, and that little blood has been lost; but in such cases coagula or clots of blood are commonly found adhering to the separated parts, a character which indicates that the wound was inflicted either during life or soon after death, while the blood was warm and fluid. When a lacerated or contused wound involves a highly vascular part, although no large bloodvessel may be implicated, it is liable to cause death by loss of blood.

Ecchymosis from violence.—Contusions and contused wounds are commonly accompanied by a discoloration of the surrounding skin, to which the term ecchymosis (*ἐκχύω*, to pour out) is applied. This consists essentially in the extravasation or effusion of blood generally from small ruptured vessels into the surrounding cellular membrane beneath the skin. An ecchymosis is commonly superficial, affecting only the layers of the skin, and showing itself externally, either immediately or in the course of a short time, in the form of a deep blue or livid red patch,

but the effusion may be so deeply seated as not to produce any external discoloration of the skin.

Violence inflicted on a living body may not show itself under the form of ecchymosis until *after death*. A man received from behind several kicks on the lower part of his abdomen, which caused a rupture of the bladder, and death by peritonitis. He died in about thirty-five hours; but there was no ecchymosis in the seat of the blows, *i. e.*, in the pubic and lumbar regions, until after death. Dr. Hinze met with a case of suicidal hanging, in which it was observed that ecchymosis appeared in the course of the cord only after death. (See "HANGING.") It has been remarked by Devergie that ecchymoses are often concealed on the bodies of the drowned, when first removed from water, owing to the sordid state of the skin; they may become apparent only after the body has been exposed for some days and the water has evaporated.

A medical jurist must guard against the error of supposing that when a blow has been inflicted on a living person, it is necessary that the individual who is maltreated should survive for a long period in order that ecchymosis may be produced. Among numerous instances proving the contrary, the case of the *Duchess de Praslin* (August, 1847) may be mentioned. This lady, who was assassinated by her husband, was attacked while asleep in bed. The number of wounds on her person (thirty) showed that there had been a mortal struggle, which, however, could not have lasted more than *half an hour*. Yet, on inspection, there were the marks of numerous ecchymoses, which had resulted from the violent use of a bruising instrument. ("Ann. d'Hyg.," 1847, t. 2, p. 377.) The late Prof. Casper of Berlin considered that ecchymosis required a certain time for its production, and that if a person died speedily from the effects of violence, no ecchymosis would be found on the body, although the violence might have been of a bruising nature. ("Handbuch der Ger. Med.," vol. 1, p. 121.) The case of the *Duchess de Praslin* shows that this is not correct, and Casper himself has admitted that ecchymosis may be produced as the result of violence applied to a recently dead body (see "STRANGULATION"), a result which is in accordance with other facts mentioned above; but if ecchymosis can be produced by violence to the recently dead, it is clear that a continuance of active life is not necessary for its production. The following case shows how these facts may be misapplied. In June, 1870, a young man was seen to strike one of his companions. The person struck died suddenly. On a post-mortem examination the mark of a bruise was seen over the sixth and seventh ribs on the right side. About a fortnight before this blow was struck, the deceased had met with an accident; a heavy box fell on his right side, knocked him senseless, and nearly killed him. The question at issue, according to Dr. Guppy, of Falmouth, who reports this case, was whether the ecchymosed mark on the side was owing to the blow struck shortly before the man died, or to the fall of the box upon his body a fortnight previously. It was suggested, on the authority of Casper, that as the man died soon after the blow was struck, the ecchymosis could not have arisen from the blow, but that it was most probably due to the fall of the box a fortnight before. ("Lancet," 1870, vol. 2, p. 35.) Such a case does not present much difficulty. If the

ecchymosed mark was blue or livid, and without any marginal colors, it was probably the result of the blow struck just before death. If the blood is fluid at the time of the violence, and the small capillary vessels are torn through, sudden death following, a blow may cause the effusion of blood, and the production of a mark on the skin. The warm liquid blood thus effused will find its way into the cellular tissue, and produce the usual external appearance. If, in the case quoted, the ecchymosis had been produced a fortnight before, it would have shown some changes of color at the margin, as described in the next paragraph.

The changes which take place in the color of an ecchymosed spot are worthy of attention, since they may serve to aid the witness in giving an opinion on the probable time at which a blow has been inflicted. After a certain period, commonly in eighteen or twenty-four hours, the blue or livid margin of the spot is observed to become lighter; it acquires a violet tint, and before its final disappearance it passes successively through shades of a green, yellow, and lemon color. During this time the spot is much increased in extent, but the central portion of the ecchymosis which received the violence is always darker than the circumference.

Contusions on the dead.—Sir R. Christison found that blows inflicted on a dead body within *two hours* after death, gave rise to appearances on the skin similar to those which resulted from blows inflicted on a person recently before death. The livid discoloration thus produced generally arose from an effusion of the thinnest possible layer of the fluid part of the blood on the outer surface of the true skin, but sometimes also from an effusion of blood into a perceptible stratum of the true skin itself. He likewise found that dark fluid blood might even be effused into the cellular tissue in the seat of the discolorations, so as to blacken or redden the membranous partitions of the cells containing the fat: but this last effusion was never extensive. From this, then, it follows, that, by trusting to external appearances only, contusions made soon after death may be easily confounded with those which have been produced by violence shortly before death. If a contusion has been caused some hours before death, there will be swelling of the part, and probably also certain changes of color in the ecchymosed patch, in either of which cases there will be no difficulty in forming an opinion. Although ecchymosis, or an appearance similar to it, may be produced on a body after death, the changes in color are then met with only under peculiar circumstances, as where the person is laboring under general dropsy, and the serum effused beneath the skin, may lead to the diffusion of the blood. The most satisfactory mark of distinction between the effects of blows on the living and dead body, in the opinion of Sir R. Christison, is the following: In a contusion inflicted during life, the ecchymosed portion of cutis (true skin) is generally dark and much discolored from the infiltration of blood throughout its whole thickness; the skin at the same time is increased in firmness and tenacity. This is not, however, a uniform consequence of a contusion during life; for a blow may cause effusion of blood beneath the skin without affecting the cutis in the manner stated. The state of the skin here described, cannot be produced by a contusion on a dead body; although it is still an open question, whether it might not be produced if the contusion were inflicted a *few minutes* after death. As it is,

the value of this sign is somewhat circumscribed—it is not always produced on the living—it might be possibly produced on the recently dead ; so that when it does not exist, we must look for other differential marks ; and when it does exist we ought to satisfy ourselves that the contusion was not inflicted recently after death.

The period at which such injuries cease to resemble each other has not been fixed with any degree of precision ; but, as in the case of incised wounds, it would seem that there is little danger of confounding them, when a contusion has not been inflicted on a *dead* body until after the disappearance of animal heat and the commencement of cadaveric rigidity.

The practical inference from these observations is, that discolorations of the skin caused by blows inflicted soon after death, may be sometimes mistaken for marks of violence on the living body. An instance has been communicated to me, on respectable authority, in which, for the sake of experiment, blows with a stick were inflicted on the recently dead body of a woman, while still warm. The body was afterwards accidentally seen by non-professional persons, who were not aware of the performance of these experiments ; and so strong was the impression from the appearances, that the deceased had been maltreated during life, that a judicial inquiry was actually instituted, when the circumstances were satisfactorily explained. The fact, therefore, that *severe* blows after death resemble *slight* blows during life, is of some importance : there is ecchymosis in each case, and no certain method of distinguishing the one from the other.

Is ecchymosis a necessary result of violence?—This medico-legal question has often created great difficulty. It has been repeatedly asserted in courts of law, that no severe blow could have been inflicted on the body of a person found dead, in consequence of the absence of ecchymosis or other indication of violence on the part struck ; but this assertion is entirely opposed to well-ascertained facts. However true the statement may be that severe contusions are commonly followed by ecchymosis, it is open to numerous exceptions ; and unless these are known to a practitioner, his evidence may mislead the court. The presence of ecchymosis is commonly presumptive evidence of the infliction of violence, but its absence does not necessarily negative this presumption.

It was long since remarked by Portal that the spleen had been found ruptured from blows or falls, without any ecchymosis or abrasion of the skin appearing in the region struck. This has been also observed in respect to ruptures of the stomach, intestines, and urinary bladder, from violence directly applied to the abdomen. Portal supposed that the mechanical impulse was simply transferred through the supple parietes (or skin) of the abdomen to the viscera behind, as in the striking of a bladder filled with water. Whether this be the true explanation or not, it is quite certain that the small vessels of the skin often escape rupture from a sudden blow, so that their contents are not effused. A case is reported by Henke, in which a laboring man died some hours after fighting with another, and on an inspection of the body the peritoneum was found extensively inflamed, owing to an escape of the contents of the small intestines, which had been ruptured to a considerable extent. There was, however, no ecchymosis or mark on the skin externally, and

the medical inspectors were inclined to affirm, contrary in this case to direct evidence, that no blow could have been struck; but others of greater experience were appealed to, who at once admitted that the laceration of the intestines might have been caused by a blow, even although there was no appearance of violence externally. Mr. Watson states that a girl, aged nine, received a smart blow upon the abdomen from a stone. She immediately complained of great pain; collapse ensued, and she died in twenty-one hours. On inspection there was no mark of injury externally, but the ileum (small intestines) was found ruptured, its contents extravasated, and the peritoneum extensively inflamed. ("On Homicide," p. 187.) Dr. Williamson, of Leith, met with a case in which a man received a kick on the abdomen from a horse: he died in thirty hours from peritonitis. The ileum was found to have been torn completely across in its lower third. There was not the slightest trace of ecchymosis externally, a fact which is the more remarkable, since the blow was here struck by a somewhat angular or pointed body—the hoof of a horse. ("Med. Gaz.," May, 1840. See also "Guy's Hosp. Reports," Oct. 1865, p. 285.) In October, 1873, a man who had been run over by an omnibus was brought into Guy's Hospital. The wheel had gone over his chest and abdomen, but on admission no injury was discoverable. On the second day peritonitis set in, from which he rapidly sank. The liver and small intestines were found ruptured. ("Guy's Hosp. Gaz.," 1873.) ("Annales d'Hygiène," 1879, 1, 477.) Many other cases might be adduced in support of the statement that ecchymosis is not a necessary or constant result of a severe blow or severe bruising violence; but these sufficiently establish the fact. This medico-legal question frequently arises in cases in which the bladder or liver is ruptured, as, owing to the general absence of marks of violence, it is often alleged in defence that no blow or kick could have been inflicted on this part of the abdomen. It is unnecessary to say that this view is not in accordance with facts. (See Ruptures of the heart, liver, spine, and intestines, *post.*)

CHAPTER XXIV.

EVIDENCE OF THE USE OF A WEAPON.—CHARACTERS OF WOUNDS CAUSED BY WEAPONS.—INCISED, PUNCTURED, LACERATED, AND CONTUSED WOUNDS.—STABS AND CUTS.—WHAT ARE WEAPONS?—EXAMINATION OF THE DRESS.—IMPUTED OR SELF-INFLICTED WOUNDS.

Evidence of the use of a weapon.—It is not necessary to prove that a weapon has been used for the production of a wound, for the words of the new statute are: "Whosoever shall, *by any means whatsoever*, wound or cause any grievous bodily harm to a person," etc.; yet evidence of the use of a weapon in cases of assault may materially affect the amount of punishment awarded on conviction. When, upon the clearest evidence,

it is certain that a weapon has been used, it is not unusual for prisoners to declare that no weapon was employed by them, but that the wound had been occasioned by accidental circumstances. A witness should remember that he is seldom in a position to swear that a particular weapon produced at a trial must have been used by the prisoner: he is only justified in saying that the wound was caused either by it or by one similar to it. Schwörer relates the following case: A man was stabbed by another in the face, and a knife with the blade entire was brought forward as circumstantial evidence against him,—the surgeon having stated that the wound had been caused by *this* knife. The wounded person recovered; but a year afterwards an abscess formed in his face, and the broken point of the real weapon was discharged from it. The wound could not therefore have been produced by the knife which was brought forward as evidence against the prisoner at the trial. ("Lehre von dem Kindermorde.") Although the criminality of an act is not affected by an occurrence of this kind, it is advisable that such mistakes should be avoided by the use of proper caution on the part of a witness. (On this question, see the case of *Renaud*, by Dr. Boys de Loury, "Ann. d'Hyg.," 1839, t. 11, p. 170. As to what is a weapon, see Henke, "Zeitschrift der S. A.," 1844, vol. 1, p. 67.)

Characters of wounds produced by weapons.—Let us now suppose that no weapon is discovered, and that the opinion of a witness is to be founded only on an examination of a wound. It is right for him to know that on all criminal trials, considerable importance is attached by the law to the fact of a wound having been caused by the use of a weapon; since this generally implies malice, and in most cases a greater desire to injure the party assailed, than the mere employment of manual force. Some wounds, such as cuts and stabs, at once indicate that they must have been produced by weapons.

1. *Incised wounds.*—In incised wounds, the sharpness of the instrument may be inferred from the cleanness and regularity with which the edges are cut: in stabs, also, the form and depth of a wound will often indicate the kind of weapon employed. Stabs sometimes have the characters of incised punctures, one or both extremities of the wound being cleanly cut, according to whether the weapon is single or double-edged. Dupuytren has remarked that such stabs, owing to the elasticity of the skin, are apparently smaller than the weapon—a point to be remembered in instituting a comparison between the size of a wound and the instrument. A lateral motion of the weapon may, however, cause a considerable enlargement of the wound. (See case "Ann. d'Hyg.," 1847, t. 1, p. 400.) When a stab has traversed the body, the entrance-aperture is commonly larger than the aperture of exit; and its edges, contrary to what might be supposed, are sometimes everted, owing to the rapid withdrawal of the instrument. That facts of this kind should be available as evidence, it is necessary that the body should be seen soon after the infliction of a wound, and before there has been any interference with it.

In general, wounds made by *glass or earthenware* are characterized by their great irregularity, and the unevenness of their edges. In *Reg. v. Ankers* (Warwick Lent Assizes, 1845), a clean cut as from a pen-knife, about two inches long and one deep, was proved to have existed

on the person of the prosecutor, who had fallen during a quarrel with the prisoner. Some broken crockery was lying near the spot, and it was alleged in the defence that a fall upon this had caused the wound. This allegation was quite inconsistent with the clean and even appearance of the edges of the wound. The prisoner, in whose possession a pen-knife had been found, was convicted.

Punctured wounds.—It is necessary to notice whether the edges of a punctured wound are lacerated and irregular, or incised; because it may be alleged in defence, that the wound was produced by a fall on some substance capable of causing an injury somewhat resembling it. In a case that occurred to Mr. Watson, a deeply penetrating wound on the genital organs of the deceased, which had evidently caused the woman's death, was ascribed by the prisoners charged with the murder, to her having fallen on some broken glass; but it was proved that the edges of the wound were bounded everywhere by clean incisions, which rendered this defence inconsistent, if not impossible. I have known a similar defence made on two other occasions, where the cases came to trial. In general, wounds made by *glass or earthenware* are characterized by their great irregularity, and the unevenness of their edges, with portions of the substance in them. Cases of this kind show that as it is not always possible to know when this sort of defence may be raised, a medical witness should never fail to make a *minute examination* of a wound which is suspected to have been criminally inflicted. These medical difficulties are now for the most part removed by the 24th and 25th Victoria, Chap. 100. This must not, however, lead the witness to suppose that a personal injury is not to be carefully examined with a view to the determination of this question.

2. *Lacerated and Contused wounds.*—Lacerated wounds do not in general present greater difficulty with regard to their origin than those which are incised or punctured. The means which produced the laceration are commonly well indicated by the appearance of the wound. These injuries are generally the result of accident; they are, however, frequently met with on the bodies of new-born children, in which case they may give rise to a charge of infanticide. If it could be proved that they had arisen from the use of a weapon, and that the weapon fitted the wounds, these facts would, of course, go far to a conviction on a charge of murder. In the case of *Montgomery* (Omagh Summer Ass. 1873) it was proved that a bill-hook, found buried in a spot to which the prisoner was seen to go, fitted the injuries produced on the skull of the deceased, and this piece of evidence served to connect the prisoner and the weapon with the act of murder, which took place in a dwelling-house.

Contused wounds and severe contusions present much greater difficulty to a medical jurist. It is not often in his power to say whether a contused wound has resulted from the use of a weapon, from a blow of the fist, or a fall, by reason of the deceased having accidentally fallen against some hard surface. The question is frequently put to medical witnesses on those trials for manslaughter which arise out of the pugilistic combats of half-drunken men. One of the combatants is generally killed, either by a blow on the head, by a fall, or by both kinds of violence combined.

The skull may or may not be fractured ; and the person may die of concussion, inflammation of the brain, or from effusion of blood. The general defence is that the deceased struck his head against some hard substance in falling on the ground, and a surgeon is asked whether the particular appearance might not be explained on the supposition of a fall. A medical witness is rarely in a position to swear with certainty that a contused wound of the head must have been produced by a weapon, and *not* by a fall. Some circumstances, however, may occasionally enable him to form an opinion on this point. If there are contused wounds on several parts of the head, with copious effusion of blood beneath the skin, the presumption is that a weapon must have been used. If the marks of violence are on the summit of the head, it is highly probable that they have been caused by a weapon, since this is not commonly a part which can receive injury from a fall. So if sand, gravel, grass, or other substances be found in a contused wound, this will render it highly probable that the injury was really caused by a fall.

It matters not, under the new statute on wounding, whether the wound was produced directly by a weapon employed by an assailant, or indirectly by any act of violence on his part. A man may fracture the skull of another either by striking him with a brick, or by striking him with his fist, and thus causing him to fall against a brick. Acquittals formerly took place upon technicalities of this kind ("Law Times," March 21, 1846, p. 501) ; but in *Reg. v. Dodd* (Shrewsbury Summer Assizes, 1853) Coleridge, J., expressed a strong opinion against the distinction thus made. The prisoner, it was alleged, threw a stone at the deceased, who immediately fell on a stone floor. The deceased was able to go about for several days, but he died a week after he had sustained the violence, from inflammation of the brain, as a result of fracture of the skull. The medical witness ascribed the fracture to a blow from a stone. In the defence it was urged that the fracture might just as well have arisen from a fall on a stone floor. Coleridge, J., held, if the prisoner knocked the deceased down, that it would make no difference whether the deceased died from a fall on a stone floor, or from injury produced by the stone which was thrown at him.

[We think there can be no doubt that a blow of the fist is capable of producing a fracture of the thin portions of the skull, *e. g.*, the temporal region, and this either with or without an external wound. In a doubtful case, where the question whether such a fracture was caused by the fist, or by some weapon, a careful post-mortem examination of the cranium would most probably determine the point ; the fracture from the fist would be very apt to be radiated, while that resulting from a weapon, such as a *billy*, or a loaded cane, or a hammer, would be more regularly depressed, and also more circumscribed.—R.]

A doubt may arise whether a *weapon* has or has not been used in reference to lacerated or contused wounds. Contused wounds on bony surfaces, as on the head, sometimes present the appearance of incised wounds, the skin being evenly separated. When a wound is recent, a careful examination will generally enable a witness to form a correct opinion, but if some time has elapsed before a wound is examined, great caution will be required in forming a judgment.

In January, 1853, Mr. Hancock was enabled, by the careful examination of a wound, to disprove a charge of maliciously wounding made against innocent persons. A little girl was represented to have received, while sitting over an iron grating, a wound in the pudendum, by some persons pushing a toasting-fork or pointed instrument between the bars of the grating from below. There were no marks of punctures, which would have been found had this statement been true, but a slight laceration of the parts, such as might have been produced by an accidental fall on the edge of the iron grating while the girl was in a sitting position. There were also marks of bruises on the thigh, such as might have occurred from an accident of this kind. The mother of the child had made a false charge for the sake of exciting public compassion and extorting money. A proper surgical examination of the injury clearly established that it had resulted from accident. The part of the body in which the injury existed in this case is not usually exposed to laceration or punctures from accident; but the child, for a certain purpose, had placed herself voluntarily in this position, and had, on her own admission, slipped, and thus probably injured herself.

A surgeon should be cautious in listening to the statement of others, that a weapon has been used, unless the wound itself bears about it such characters as to leave the fact indisputable. During a scuffle, the person assaulted may be easily deceived as to the way in which an accused person inflicted a wound upon him; and a bad motive may sometimes exist for imputing to an assailant the use of a weapon during a quarrel. In such cases we should, as medical witnesses, rather trust to the appearance of the wound for proof of the use of a weapon, than to any account given by interested parties.

A late learned judge suggested to me that some means of discrimination between the effects of falls and blows affecting the same part of the body, would greatly aid the administration of justice. There is no doubt that it would, but as no two cases coming under this class of injuries are precisely alike either in the part wounded, or the amount of force employed, it is scarcely possible to introduce general rules or to make statistics practically available. It is commonly supposed that a mere fall is not sufficient to produce the same degree of injury that may be caused by a blunt weapon applied suddenly to the head by human force; but a severe fracture may arise from a simple accident of this kind, and present nearly all the characters of homicidal violence. The difficulties at criminal trials will, I think, be found to proceed, not so much from want of rules to assign the violence to one condition or the other, as from a want of proper observation when the wounds are first examined. If minute attention were given to an examination of these injuries soon after their occurrence, circumstances would be noticed which would help the medical witness to a conclusion. The defence that they might have been produced by a fall is not set up until a subsequent period, and the surgeon is then obliged to trust to his memory for the main points of distinction. Such improvised opinions usually fail in impressing a jury.

When it is a question which of two weapons produced certain bruised wounds found on the head, the difficulties of medical evidence are in-

creased. Under these circumstances the presence of blood, hair, cotton, or woollen fibres on one of the weapons, may render it probable that this weapon was used. In most instances an accurate observation of the form of a contused wound and an early comparison of it with the alleged weapon, or the substance said to have produced it, will enable a witness to come to a correct conclusion on the subject. The situation, depth, and shape of the wound may be such that no accidental fall could reasonably account for its production. In assaults on women, it is not unusual to find that the complainant herself endeavors to exculpate the assailant (her husband) by ascribing the marks of violence, not to blows, but to some accidental fall. In August, 1864, a woman deposed before a magistrate that certain severe injuries which she had sustained had been caused by her falling on a fender. The medical man who examined her, found on the top of the head three distinct wounds, which were bleeding. Two appeared as if they had been caused by a blunt instrument; the third on the back of the head was a clean cut wound. He considered that they had been produced by a chopper, and that none of them had been caused by a fall or a series of falls. The prisoner on this evidence was committed for trial.

If the fall has taken place from a great height, as over a precipitous or rugged slope, it is obvious that the body may sustain many severe injuries to various parts quite sufficient to account for death. Such a fall may be the result of accident, of suicide, or as in the case of *Madame de Tourville*, July, 1876, of a deliberate design to destroy life by pushing the person over the precipice. The injuries would be similar in each case. *De Tourville*, a barrister, was charged before the Austrian Court at Botzen, with the murder of his wife by pushing her over a precipice in the Stelvio Pass of Switzerland. Her lifeless body was found at a considerable depth below. The chief seat of injury was the head, which had been crushed by the fall. There was nothing in the appearance of the body to show intentional violence. The guilt of the prisoner was made out by false and inconsistent statements which he had made respecting the occurrence. There were marks of the body having been dragged some distance, and part of the dress in a bloody state was found at a distance from the spot where the body was lying, and there were marks of blood on the prisoner's hands and dress. After a lengthy trial, during which the spot was visited by the judge and jury, *De Tourville* was found guilty and sentenced to death. This sentence was subsequently commuted to imprisonment for life.

3. *Stabs and cuts*.—It has been remarked that the law in some cases attaches great importance to the clear proof of the use of a *weapon*; and a medical man has therefore a certain responsibility thrown upon him when, in the absence of a weapon and the denial of its use, he is called upon to say whether one has, or has not been used. In reference to cuts and stabs, there can in general be no difficulty, for these injuries carry with them distinct evidence of their mode of production. Formerly, stabbing and cutting were treated as distinct from wounding, and very nice legal distinctions were drawn between these terms, which had the effect of procuring acquittals on mere legal technicalities. Under the new consolidated act, the words "stab" and "cut"

are properly omitted, and the word "wound" only has been retained. Medical men would always agree upon a stab or cut being a wound, but they might reasonably differ upon the question whether in a given case a wound was really a stab or a cut. It might be punctured, lacerated, or contused, and not fairly come under the professional description either of a cut or a stab. In the mean time, the only person who derived benefit from this grammatical confusion, was the assailant who had inflicted the undefined injury on another. A medical witness has now only to prove that the personal injury falls strictly within the meaning of the term *wound* (p. 257); he is not called upon to prove the precise variety of wounding to which the injury should be assigned. At the same time, he should always be prepared with a full description of the characters of an injury in case questions on the subject should be put to him.

What are weapons?—The new statute has removed those legal subtleties which raised doubts on the true significance of the term *weapon*. Thus the teeth, the hands or feet uncovered, were formerly held by the judges *not* to be weapons; and injuries produced by them, however severe, were not treated as wounds within the meaning of statute. Persons were tried on charges of biting off fingers and noses, and although the medical evidence proved that wounds of a severe kind had been inflicted, and that great disfigurement and mischief had been done to individuals, yet the nature of the injury produced was not so much regarded as the actual method by which it was accomplished. The persons charged were acquitted under an indictment for "wounding," since wounds, in a legal sense, could be produced only by weapons, while the teeth, hands, and feet were not weapons in law!

Examination of the dress.—This is sometimes a most important part of the duty of a medical man. In a case of severe wounding, of whatever kind, he should always require to see the dress of the wounded person. It may throw a material light upon the *mode* in which a wound has been produced; it may remove an erroneous suspicion of murder, and may sometimes serve to indicate that a wound has been self-inflicted for the concealment of other crimes, or falsely to impute its infliction to other persons. Marks of blood, dirt, grass, or other substances on the clothing, may also throw a light on the mode of infliction. So again the use of a weapon, in reference to cuts and stabs, may be inferred from the dress presenting corresponding cuts or perforations. Contused wounds by bludgeons may, however, be readily produced through the dress, without tearing or injuring it. Considerable laceration of the skin and muscles, and even severe fractures, may be caused without necessarily penetrating the dress, supposing it to be at all of an elastic or yielding nature. In self-inflicted or imputed wounds, if of the nature of cuts or stabs, there is often a want of correspondence between the perforations of the dress and the wounds on the person: this is one of the characters by which the correctness of a statement may be tested. A severe wound may be indirectly produced by a bruising weapon, and medical witnesses have been often questioned on this point. Thus, the prosecutor may at the time have worn about his person some article of dress which received the blow, and this may have actually caused the wound. Cases of this kind must be determined by the circumstances

which accompany them. Hence it is obvious that a medical practitioner should always make a minute and careful examination of wounds which are likely to become the subject of criminal charges, as well as of the dress and clothing worn by the wounded person at the time of the assault. In performing his duties as a surgeon, he is bound, so far as he consistently can, to notice as a medical jurist the characters of all personal injuries, so as to be able to give an opinion on the mode in which they were produced. A careful examination of the dress has served to remove doubts respecting the mode in which contused wounds have been inflicted on the body of a person found dead; while, on the other hand, a neglect to examine the dress has led to accidental being mistaken for homicidal violence, as in the following case, communicated to me by Mr. Codd, coroner for Essex.

A woman, æt. 60, was found dead in her bed. She had vomited slightly, and there was a small quantity of blood on the floor, which had flowed from her nose. She had been seen in her usual health on the previous night. On inspection there were found two indentations about the middle of the right parietal bone, and there was a large clot of blood in this situation beneath the skin. On removing this clot, the bone was found fractured to the extent of four inches. Nearly three ounces of dark clotted blood were found on the outer membrane of the brain (*dura mater*), between it and the skull. All the other viscera were healthy. This was the only injury, and quite sufficient to account for death; but a question arose respecting the mode in which this fracture was caused. It was in evidence, that on the evening before her death, deceased had been suddenly knocked down, while she was walking in a public road, by a man accidentally running against her. One witness stated that she fell heavily on the back of her head, on which at the time she wore a bonnet. She appeared stunned—was raised up by the men—some brandy was given to her, and she recovered sufficiently to walk home and eat her supper as usual, after which no one saw her until she was found dead in bed on the following morning. Some suspicion arose that the violence done to the head was too great to be accounted for by a mere fall, and it was a question whether, with such an amount of injury, the deceased could have walked to her home, at the distance of a mile and a half, and have eaten her supper before going to bed. At first it was thought that this was a case of murder, and a man who lodged in the house with deceased was suspected. His room was searched, and a hammer with two claws was found. On comparing these claws with the two indentations and fracture, the medical witness thought that this weapon would at once account for their production. Deceased and this man had been in the habit of quarrelling, and they were the only persons in the house on this occasion. The lodger said that he let the woman in about nine o'clock (the fall in the road occurred about 7.30); her appearance presented nothing unusual, and he saw no more of her until called at seven the next morning, when she was found dead and cold. It was only at the adjourned inquest that the *bonnet* worn by the deceased at the time of the fall was called for by the coroner. Two indentations were then found upon the back part of it, corresponding to those on the skull of deceased. The indentations on the bonnet contained dust and dirt, there

by confirming the statements of the witnesses, and rendering it probable that the fall in the road had really caused the fatal injury to the head. The examination of the dress, in this case, cleared up what might have been otherwise doubtful. It is probable that the large internal effusion of blood which had caused death, did not take place until deceased had reached home, and perhaps as a result of the exertion made. She must have died very soon after she went to bed, as her body was found cold at seven o'clock the next morning. In addition to the caution which this case conveys respecting medical opinions on the origin of wounds, it shows that persons may walk and die at a great distance from the spot where a serious injury to the head has been sustained.

If several wounds have been inflicted through the *dress*, an examination of this may sometimes suffice to show which was first received. A man, in struggling with an assailant, received three stabs with a knife—two on the left elbow and a third in the back. The latter was at about the level of the eighth rib; it was vertical to the chest and had clean edges. The lower margin was obtuse—the upper acute; hence it was evident that the cutting edge of the weapon had been directed upwards. It had traversed the left lung and the heart, and had caused immediate death. It was obvious, on examination, that this mortal wound had been first received, and the stabs at the elbow inflicted subsequently. These two stabs, which were slight, had divided the cloth coat and shirt, and had only grazed the skin, so that no blood had been effused. But the edge of the cuts in the cloth coat and shirt were stained with blood; hence it was evident that they must have been produced by a weapon already rendered bloody by a previous wound. The fact was of some importance in the case, and the correctness of the medical opinion was confirmed by the evidence at the judicial inquiry. (See “*Ann. d’Hygiène*,” 1847, p. 461.)

Imputed or self-inflicted wounds.—A man may produce upon himself one or more wounds for the purpose of simulating a homicidal assault, which he may allege to have been committed upon him. With the motives for the self-infliction of wounds a medical jurist is not concerned—it is of the fact only that he can take cognizance. From the cases that have yet occurred, it would appear that the object has been to extort money, to conceal murder, robbery, or some other crime, and to turn away a suspicion of criminality from the wounded person himself; but it is not always easy to trace a motive for the self-infliction of injuries; and when a reasonable motive is not at once forthcoming, persons are apt to be misled and to credit the story. Persons who have been convicted of thus imputing violence to others have frequently borne respectable characters until the occurrence, and this has contributed to give support to their statements. When a person intending to commit suicide fails in the attempt, he has sometimes, under a sense of shame, attributed the infliction of a wound in his throat to another; but facts of this kind may without difficulty be cleared up by circumstantial evidence. Imputed wounds, if we except the case of an actual attempt at suicide, in which the injury is commonly severe, and generally of a *superficial* character, consisting of cuts or incisions not extending below the true skin; deep stabs are seldom resorted to where the purpose is not suicide but merely to conceal other crimes. Further, these wounds are in *front* of the per-

son, and may be on the right or left side, according to whether the person is right or left-handed. They have also been generally *numerous*, and widely scattered; sometimes they have had a complete parallelism, unlike those which must have been inflicted by an adversary during a mortal conflict with a weapon. The *hands* are seldom wounded, although in the resistance to real homicidal attempts these parts commonly suffer most severely. The injuries are not usually situated over those parts of the body in which wounds are by common repute considered *mortal*, and there is in general an entire want of correspondence between the situation of the wounds on the person, and the cuts or other marks on the *dress*. This is a fact which requires special attention.

In comparing cuts on the *dress* with wounds on the person, there are several circumstances to be attended to. What articles of dress were worn at the time of the assault? In a case of actual stabbing by another, all ought to present marks of perforation, corresponding in direction, form, size, sharpness of the edges of the weapon, etc. In imputed wounds, the marks on several layers of dress may not correspond with each other in the characters above mentioned. It is very difficult for a man simulating such injuries, so to arrange his clothes when off his person as to deceive a careful examiner. There will be some inconsistency or want of adjustment. Apart from the fact that several stabs or cuts cannot exist on the same part of the clothes, without one or more being stained with blood from the outside or inside, an impostor may either do too much or too little, and thus lead to his detection. In a case which excited much public discussion in London many years since, a simple circumstance led to the inference that certain stabs or cuts through a shirt had not been produced while the shirt was on, but while it was off the body. There were two cuts in the shirt near to each other, precisely similar in size, form, and direction; in fact, the knife or dagger producing them must have gone through a fold of the shirt, so accurate was the correspondence. Then, however, it followed that the shirt could not have been upon the body of the wounded person, as he alleged, because a stab through a shirt when worn over the skin must, in order to reach the body, traverse not only a fold (producing two cuts), but a single layer in contact with the skin, and thus produce *three cuts*, or in the event of traversing two folds, *five cuts*. In simulating the wounds by cuts on the shirt, the person is supposed to have forgotten this, and have merely stabbed a fold of the shirt while lying on a table, or in some situation convenient for the purpose. This, among other facts, rendered it probable that the slight wounds on the chest were self-inflicted. A case occurred at Nottingham in February, 1872, which shows how persons who inflict wounds, and at the same time cut the dress covering the wounded part, may furnish evidence against themselves. A youth charged a man with unlawfully wounding him on the highway. He stated that the man had stabbed him in the arm, cutting through his shirt and coat-sleeve. There was no attempt at robbery, and no motive for such an act. On examining the coat and shirt-sleeve it was found that they had been cut, but there was no corresponding cut in the lining of the coat-sleeve. The prosecutor could give no explanation of this. It was clear that the charge was false, that there had been no cutting or stabbing by

another, but that the wound was self-inflicted when the coat was not worn. The youth wished to leave the place where he had been sent for private study, and he had adopted this singular plan to induce his friends to remove him.

It has been contended that no rules can be laid down for the detection of such cases; each must be decided by the facts which accompany it. The facts which a medical man must endeavor to ascertain are the following: 1. The relative positions of the assailant and the assailed person at the time of the alleged attack. 2. The situation, direction, and depth of the wound or wounds. 3. The situation or direction of marks of blood or wounds on the person or dress of either, or of both the assailant and assailed; and, 4. The marks of blood, and the quantity effused at the spot where the mortal struggle is alleged to have taken place. The importance of these inquiries cannot be over-estimated. A strong suspicion was raised against the then Duke of Cumberland, in the year 1810, in reference to the death of *Sellis*, when a proper examination of the wounds on the deceased would have shown that they might have been self-inflicted.

It is worthy of remark that imputed wounds are generally *cuts* or *stabs*. They are seldom of the contused kind; the impostor cannot, in reference to contusions, so easily calculate upon the amount of mischief which is likely to ensue. Dr. Bergeret, however, has related some cases in which females laboring under hysterical attacks have inflicted upon themselves severe contusions, and have charged innocent persons with attempts to murder. ("Ann. d'Hyg.," 1863, vol. 1, p. 463.) In general the inconsistency of the story is so palpable as to betray the imposture at once; but the public are easily deceived, and much prejudice is often unjustly excited against those who have been falsely accused. Slight excoriations or bruises may be magnified into marks of murderous violence; and if a medical man can be found to admit, in an unqualified form, that a severe blow may be inflicted and yet leave but slight marks on the skin, the charge will be considered proved against the unfortunate accused!

The case of *M. Armand*, a merchant of Montpellier, who was tried at the Assizes at Aix, in March, 1864, for an alleged murderous assault upon his servant Maurice Roux, furnishes a good illustration of the readiness with which the most inconsistent stories are accepted by the public, when they are supported by pseudo-medical evidence. This case was rather one of imputed homicidal strangulation than imputed wounding; nevertheless a foundation was laid for medical opinions by the presence, as it was alleged, of a slight excoriation of the skin on the nape of the neck. The injury was so slight that it escaped the observation of some medical men who examined the complainant, and there could be no doubt from the facts that it had been produced either accidentally or designedly by the complainant on himself. Several medical gentlemen, taking the man's story as true, asserted without any qualification: 1. That a blow on the nape of the neck might produce cerebral concussion and syncope. 2. That a blow to produce such effects need not be violent; and 3. That such a blow so inflicted, would not always leave upon the skin marks of contusion or ecchymosis. These admissions were taken

by the court to support the man's story, that his master had struck a severe blow on the back of his neck, that this blow had produced concussion of the brain, and that he had been rendered insensible for many hours. ("Ann. d'Hyg.," 1864, 1, 451.) The evidence for the defence, and chiefly that given by M. Tardieu, removed the evil effect produced by such loose medical statements as these, and satisfied the jury that the story of the complainant was a pure fabrication. The accused was justly acquitted of the charge. Although it has been elsewhere stated that severe blows are not always attended with external marks of violence (p. 264), it by no means follows that such blows have been struck in all cases in which the skin presents a slight abrasion. This would be converting the exception into the rule, and every superficial injury might be thus distorted into a proof of the infliction of murderous violence.

Pistol-shot wounds are sometimes voluntarily inflicted for the purpose of imputing murder or extorting charity. A man intending to commit suicide by fire-arms, and, failing in the attempt, may, from shame and a desire to conceal his act, attribute the wound to the hand of some assassin. In examining such imputed wounds they will not be found to involve vital parts, except in cases of attempted suicide, and they will possess all the characters of near-wounds produced by gunpowder, wadding, or a bullet. The skin around will be more or less lacerated and bruised; there will be much ecchymosis, and the hand holding the weapon, as well as the dress and the wounded skin, may be blackened or burnt by the exploded gunpowder. A pistol-shot wound from an assassin may be produced from a distance, while an imputed wound which is inflicted by a person on himself must always partake of the characters of a near wound.

CHAPTER XXV.

WOUNDS INDICATIVE OF HOMICIDE, SUICIDE, OR ACCIDENT.—EVIDENCE FROM THE SITUATION OF A WOUND.—EVIDENCE FROM NATURE AND EXTENT.—EVIDENCE FROM THE DIRECTION OF A WOUND.—WOUNDS INFLICTED BY THE RIGHT OR LEFT HAND.—SEVERAL WOUNDS.—USE OF SEVERAL WEAPONS.

Wounds indicative of Homicide, Suicide, or Accident.—Supposing that the wound which is found on a dead body is proved to have been caused before death, it may be necessary to inquire whether it was the result of *suicide*, *homicide*, or *accident*. It might at first sight be considered that the determination of a question of this nature was wholly out of the province of a medical jurist. In some instances it may be so, and the settlement of it is then properly left to the legal authorities; but, in a large number of cases, it is so closely dependent for its elucidation on medical facts and opinions, that juries could never arrive at a satisfactory decision without medical evidence. Let us suppose, then, that a medical jurist is consulted in a doubtful case; what are the points

to which he should direct his attention? They are, with regard to the wound, 1, its *situation*; 2, its *nature* and *extent*; and, 3, its *direction*.

1. *Evidence from the situation of a wound*.—It is a general principle, in which most medical jurists agree, that wounds inflicted by a suicide are usually confined to the fore or lateral parts of the body. The throat and chest are commonly selected when cutting instruments are employed; while the chest, especially in the region of the heart, the mouth, the orbit, and the temples are the spots generally chosen for the perpetration of suicide by fire-arms. But it is obvious that any of these parts may be also selected by a murderer, with the especial design of simulating a suicidal attempt; therefore the mere situation of a wound does not suffice to establish the fact of suicide. Some have regarded it as fully established in legal medicine, that when wounds exist at the back part of the body, it is a positive proof that they have not been self-inflicted. This situation is certainly unusual in cases of suicide; but, as Orfila observes, it is not the situation, so much as the direction of a wound, which here furnishes evidence against the presumption of suicide. A wound, traversing the body from behind to before in a direct line, is not likely to have resulted from a suicidal attempt; at least it must be obvious that it would require more preparation and contrivance on the part of a self-murderer so to arrange matters that such a wound should be produced, than we can believe him to possess at the moment of attempting his life. Besides, his object is to destroy himself as quickly and as surely as circumstances will permit; he is, therefore, not likely to adopt complicated and uncertain means for carrying this design into execution. Nevertheless, we must not always expect to find suicidal wounds in what an anatomist would pronounce to be the most appropriate situation to produce instant destruction. An incised wound in a concealed or not easily accessible part is presumptive of murder; because this kind of injury could have resulted only from a deliberate use of the weapon. Suicidal wounds are, however, sometimes found in unusual situations. Thus the bloodvessels of the arms or legs may be the seat of injury. *Abdul Aziz*, late Sultan of Turkey, was found dead under suspicious circumstances. The arms presented two gashes at the bend of each elbow in front. The direction of both of these wounds was oblique from above downwards, and from within outwards, and their edges were jagged. That on the left arm penetrated to the joint. The superficial veins and the deep-seated tissues were cut through, and the ulnar artery laid open but not entirely divided. The wound on the right arm was superficial, involving only the skin and the veins. The bleeding from the ulnar artery and veins had led to death. The dress was soaked with blood. A pair of scissors stained with blood was found upon the sofa. Although the situation of these wounds is unusual, there is nothing in them inconsistent with suicide. The body was examined by nineteen physicians, and they agreed in signing a report that the act was suicidal. Unfortunately they assigned as one of their reasons, “that the *direction* and *nature* of the wounds, as well as the instrument which might have effected them (the scissors), lead to the conclusion of suicide,” whereas it is perfectly clear from the description that such wounds as these might have been easily produced by an assassin, and that their situation,

nature, and direction are very unusual in cases of suicide. In reference to this subject, it has been truly remarked that there is no wound which a suicide is capable of inflicting upon himself which may not be produced by a murderer; but there are many wounds inflicted by a murderer which, from their situation and other circumstances, a suicide would be incapable of producing on his own person. We cannot always obtain certainty in a question of this kind; the facts will often allow us to speak only with different degrees of probability.

The situation of a wound sometimes serves to show whether it is of an *accidental* nature or not—a point often insisted on in the defence. Accidental wounds are generally found on those parts of the body which are *exposed*. Some wounds, however, forbid the supposition of accident even when exposed; as deeply incised wounds of the throat, and gunshot wounds of the mouth and temples. For the report of a case in which an accidental wound on the head by an axe, closely simulated a homicidal wound, see Casper's "*Wochenschrift*," May 24, 1845.

2. *Evidence from the nature and extent of a wound.*—Contused wounds are rarely seen in cases of suicide, because in producing them there is not that certainty of speedily destroying life to which a self-murderer commonly looks. There are, of course, exceptions to this remark; as where, for instance, a man precipitates himself from a considerable height, and is wounded by the fall. Circumstantial evidence will, however, rarely fail to clear up a case of this description. Greater difficulty may exist when life is destroyed by a contused wound, voluntarily inflicted. When persons laboring under insanity or delirium commit suicide, they often inflict upon themselves wounds of an extraordinary kind,—such as would, at first view, lead to a suspicion that they had been produced by the hand of a murderer: and, therefore, the rules which are here laid down to distinguish homicidal from suicidal wounds, must be guardedly applied to cases of this kind. In 1850, a case occurred at Guy's Hospital, in which a patient in a fit of delirium tore away the whole of the abdominal muscles from the lower and fore part of the abdomen. Had the body of this person been found dead with such an unusual and serious personal injury, it is not improbable that it would have been pronounced homicidal and not suicidal. In January, 1876, a French artisan was found dead, with a severe wound in his throat. He had weighted a large knife with heavy stones, and had placed it between two upright planks, on the principle of the guillotine. He had so placed his neck, that when the knife fell by releasing a string it would cause a fatal wound. In the following case, but for the facts being known, an accidental wound in a concealed part of the body might have been pronounced to be homicidal. A girl æt. 15, while jumping on to the knee of her uncle, received a severe wound under the following circumstances. He was holding a stick between his legs, which the girl did not observe. In the act of jumping, this passed up the anus. She withdrew the stick, and though she complained of pain she amused herself as usual. On the following night acute symptoms set in, and she died in forty-eight hours, of peritonitis. A rent was found in the forepart of the rectum which had penetrated the peritoneal cavity ("*Brit. Med. Jour.*," Sept.

1874, p. 403). The body of a man was found in a lane near Rhyl. It appeared that the deceased had stretched himself on his back on the ground, unbuttoned and turned back the lower part of his vest on the left side, and had then thrust the long thin blade of a pocket knife into the heart, between the fifth and sixth ribs. The knife was found on his breast, close to the wound. The body was warm when found. He had not been disturbed: there had been no robbery of his person, his hat remained on his head, and his gloves in his left hand. He had arrived at Rhyl that afternoon. Everything indicated great deliberation.

The *extent* of a wound, by which we are to understand the number and importance of the parts injured, must in these cases be always taken into consideration. It has been somewhat hastily laid down as a rule that an extensive wound of the throat, involving all the vessels and soft parts of the neck to the spine, could not be inflicted by a suicide. Although, in general, suicidal wounds of this part of the body do not reach far back, or involve the vessels of more than one side, yet we find occasionally that all the soft parts are thus completely divided. These are cases in which, perhaps, with a firm hand, there is a most determined purpose of self-destruction. In a case of suicide, observed by Marc, the weapon had divided all the muscles of the neck, the windpipe, and gullet,—had opened the jugular veins and both carotid arteries,—and had even grazed the anterior ligaments of the spine. A wound so extensive as this is rarely seen in a case of suicide, but there is no ground for the assertion that such extensive wounds in the throat are incompatible with self-destruction. (See also “Ann. d’Hyg.,” 1872, 1, p. 419.)

Incised wounds in the throat are generally set down as presumptive of suicide, but murderers sometimes wound this part for the more effectual concealment of crime. Circumstances connected with the form and direction of a wound may in such cases lead to detection, for, unless the person attacked be asleep or intoxicated, resistance is offered,—evidence of which may be obtained by the presence of great irregularity in the wound or the marks of other wounds on the hands and person of the deceased. The peculiar form of a wound on the throat has sometimes led to a justifiable suspicion of homicide. In one instance a man was found dead with his throat cut in the manner in which butchers are accustomed to kill sheep. This led the medical man to believe that the wound had been inflicted by a butcher. The police, guided by this observation, arrested a butcher, who was subsequently tried and convicted of this act of murder. In some instances, however, it is extremely difficult to say whether the wound is homicidal or suicidal,—the medical facts being equally explicable on either hypothesis. (See case by Marc, “Ann. d’Hyg.,” 1830, t. 2, p. 408; another by Devergie, *ib.* 414; and a third by M. Ollivier, “Ann. d’Hyg.,” 1836, t. 1, p. 394.) *Regularity* in a wound of the throat has been considered to be presumptive of suicide. This was the publicly-expressed opinion of Sir Everard Home in the well-known case of *Sellia*. The deceased was found lying on a bed, with his throat extensively cut, and the edges of the incision were regular and even. This condition of the wound, it was inferred, repudiated the idea of homicide, but, as a general principle, it appears to me to be a fallacious criterion. A murderer, by surprising his victim from behind, by having others at

hand to assist him, or by directing his attack against one who is asleep or intoxicated, or who from age or infirmity is incapable of offering resistance, may easily produce a regular and clean incision on the throat.

3. *Evidence from the direction of a wound.*—The direction of a wound has been considered by some to afford presumptive evidence sufficiently strong to guide a medical jurist in this inquiry. It has been remarked that in most suicidal wounds which affect the throat, the direction of the cut is commonly from left to right, either transversely or passing obliquely from above downwards: in suicidal stabs and punctured wounds the direction is commonly from right to left and from above downwards. In left-handed persons, the direction would, of course, be precisely the reverse. Suicidal wounds are, however, subject to such variation in extent and direction that it is scarcely possible to generalize with respect to them. Nevertheless, an attention to these points may sometimes be of real assistance to the inquirer, especially when the body has not been removed from its position. It is recommended that the instrument with which the wound has been inflicted should be placed in either hand of the deceased, and the arm moved towards the wounded part, so that it may be clearly seen whether the direction of the wound could or could not correspond to it in any position. It might happen that neither arm would reach the wounded part, so as to inflict a wound of the particular direction observed: this may be the case in wounds situated on the back. It is obvious that if a murderer makes an incised wound in the front of the throat from behind, the direction will be the same as that commonly observed in cases of suicide. (See on this point the case of *Reg. v. Dalmás*, Cent. Crim. Court, May 1844.) Again, if the person attacked is powerless, the wound may be deliberately made, so as to simulate a suicidal act; indeed, murderers seldom attack the throat but with the design of simulating an act of suicide. A homicidal stab may also take the same direction as one which is suicidal, but this wound would be confined to those cases in which the assailant was placed behind or aside. If in front of the person whom he attacks, the direction would probably be from left to right; but in suicide, when the right hand is commonly used, it is the reverse. Oblique wounds, passing from above downwards, are common to homicide and suicide, but those which take an oblique course from below upwards are generally indicative of homicide, for it is extremely rare that a person bent on suicide, unless a lunatic, thus uses a weapon. Homicidal incisions, especially in the throat, are often prolonged below and behind the skin forming the angles of a wound, deeply into the soft parts. Those which are suicidal rarely possess this character; they terminate gradually in a sharp angle, and the skin itself is the furthest point wounded,—the weapon is not carried either behind, below, or beneath it. Suicides may graze the ligaments in front of the spinal column, but that they should make deep incisions into the bones, cut off hard bony processes, and divide the intervertebral substance and the vertebral arteries, is a proposition contrary to all experience and probability. The case of the *Earl of Essex*, who was found dead in the tower in July, 1683, bore somewhat on these points. The deceased was discovered with his throat cut, and a razor lying near him. This razor was found to be much notched, while the throat was

smoothly and evenly cut from one side to the other and to the vertebral column. Some considered this to have been the act of suicide, others of murder. Those medical witnesses who supported the view of suicide were asked to explain how it was that such an even wound could have been produced by a notched razor. They attempted to account for this by asserting that the deceased had probably drawn the razor backwards and forwards across the neck-bone; forgetting that before this could have been done by the deceased, all the great vessels of the neck must have been divided! Exceptions to these characters of homicidal and suicidal wounds may exist; but in a dark and intricate subject of this nature, we have only limited rules to guide us. The instrument with which a wound is supposed to have been inflicted should be adapted to the edges of the incision; its sharpness compared with the cleanness and evenness of the cut, and its length with the depth of the incision or stab. It is no uncommon occurrence for a murderer to substitute some instrument belonging to the deceased or another person for that which he has actually employed; and this by its size, shape, bluntness, or other peculiarities, may not account for the appearances presented by the wound.

It is not often that any difficulty is experienced in distinguishing a *suicidal* from an *accidental* wound. When a wound has really been suicidally inflicted, there are generally to be found about it clear indications of design; and the whole of the circumstances are seldom reconcilable with the supposition of accident. But if the position of the deceased with respect to surrounding objects has been disturbed, if the weapon has been removed, and the body transported to a distance, then it will not always be easy to distinguish a wound accidentally received, from one inflicted by a suicide or a murderer. The evidence of those who find the body can alone clear up the case; and the medical witness may be required to state how far this evidence is consistent with the situation, extent, and direction of the wound found on the deceased. It is unnecessary to dwell further on this subject, since the observations already made, will suggest to a practitioner the course which he should pursue. Circumstantial evidence is commonly sufficient to show whether a wound has been accidentally received or not; but as an accidental wound may sometimes resemble one of homicidal or suicidal origin, so it follows that it is not always possible for a medical jurist to decide the question peremptorily from a mere inspection of the wound.

It would not be difficult to produce instances in which murderers have alleged, in defence, that the wounds observed on the bodies of their victims were of accidental origin, and the allegations have been clearly refuted by medical evidence. A witness must be prepared, therefore, in all cases in which death has taken place in secrecy, and the nature of the wound is such as to render its origin doubtful, to be closely examined by counsel for a prisoner charged with felonious homicide, on a question whether the wound might not have been accidental. The law requires that it should be rendered evident to a jury, before such a charge can be sustained, that the fatal wound could *not* have had an accidental or suicidal origin. The subject of wounds of the neck has been examined in relation to homicide, suicide, and other medico-legal questions, by Dr. Güterbock, of Berlin. ("Eulenberg's Vierteljahrschrift," 1873; 2, p. 1.)

Wounds inflicted by the right or left hand.—Some remarks have been made in reference to the direction of a cut or stab varying according to whether the right or the left hand has been used by a suicide. It is necessary for a medical jurist to be aware, that there are many persons who are *ambidextrous*, *i. e.*, who have equal facility in the use of the right and the left hand. This may not be generally known to the friends of the deceased; and such persons are often pronounced, even by those who have associated with them, to have been right-handed. A want of attention to this point is said to have been one of the circumstances which led to a suspicion of murder in the case of *Sellis*. (Wills' "Circ. Evidence," p. 97.) The man was found dead on his bed with his throat cut,—the razor was discovered on the left side of the bed; whereas, it was generally supposed and asserted that he was right-handed. The truth was, he was ambidextrous,—equally expert in the use of the razor with his left and right hand; and thus the apparently suspicious circumstance of the razor being found on his left side, was at once explained away. The importance of making due allowance for the characters presented by wounds in the throat is also illustrated by a case which occurred in London, in November, 1865. A publican and his wife had been frequently in the habit of quarrelling. One night the wife gave an alarm, and the man was found dead on the bed, with his throat severely cut. On examination, the fatal wound had all the characters of a left-handed cut, while the deceased was generally believed to be right-handed; and there was bloody water in a wash-hand basin in the room. The wife, who had marks of bruises upon her, said that she left her husband in the bedroom for a short time, and on her return found him dead. The suspicious facts were explained at the inquest by a daughter of the deceased by a former marriage. She stated that her father had been brought up as a wood-carver, a trade which requires a man to use both hands equally well,—that he had frequently threatened to destroy himself, and that the blood in the wash-basin was owing to her having washed her hands after she had touched her father's head. This satisfactorily explained the medical circumstances, which appeared at first to point to an act of homicide.

The presence of several wounds.—In suicides, commonly, one wound only is seen, namely, that which has destroyed life, and the presence of several wounds on the body, or the marks of several attempts around the principal wound, have been considered to furnish presumptive evidence of murder. But any inferences of this kind must be cautiously drawn, since not only may a murderer destroy his victim by one wound, but a suicide may inflict many, or leave the marks of several attempts before he succeeds in his purpose.

The number, situation, and direction of the wounds found on a dead body may be medically inconsistent with the theory of a suicidal origin. The following case occurred in New York in September, 1839. A woman was found dead, and there were many wounds upon her body. The husband was suspected of having killed his wife, but he asserted that she had destroyed herself. This defence, however, was shown to be inconsistent with the medical facts. Three physicians who examined the body deposed that there were eleven wounds (stabs), eight on and

about the left side of the thorax, one of which had penetrated the pericardium, and divided the trunk of the pulmonary artery at its origin; and the others were in the back, near the left scapula. It was considered to be quite impossible that these last-mentioned stabs could have been produced by the deceased, and there was every reason to suppose that the stabs in front and at the back had been inflicted at the same time by an assassin. In acts of murder perpetrated by lunatics or persons laboring under delirium tremens, it is usual to find a large number of wounds on the body of the person attacked. In a case communicated to me by Dr. Procter, of York (June, 1871), a man in a fit of delirium tremens killed his wife by cutting and stabbing her. Dr. Procter found on the body of deceased fifty-six wounds, of which some were of a nature inconsistent with the theory of self-infliction. The object with such criminals is apparently not merely to kill, but to mangle the body of the victim.

The use of several weapons.—In general, suicides, when foiled in a first attempt, continue to use the same weapon; but sometimes, after having made a severe wound in the throat, they will shoot themselves, or adopt some other method of self-destruction. These cases can only appear complicated to those who are unacquainted with the facts relative to self-murder. Neither the presence of several wounds by the same kind of weapon, nor of different wounds by different weapons, can be considered of themselves to furnish any proof of the act having been homicidal. In one instance which is reported, a lunatic, in committing suicide, inflicted *thirty* wounds upon his head. In a case of murder, when many wounds are found on a dead body, it may happen that the situation or direction of some will be incompatible with the idea of a suicidal origin. Thus a stab or cut may be close to a contusion or contused wound, and although a fall or other accident might account for the latter, the former would indicate violence separately inflicted.

Two or more mortal wounds.—When we find several wounds on the body of a suicide, it generally happens that one only bears about it a *mortal* character, namely, that which has caused death. On this account it has been asserted by some medical jurists, that when two mortal wounds are found upon a body, and particularly if one of them is of a stunning or stupefying tendency (*i. e.* affecting the head), they must be considered incompatible with suicide. An inference of this kind can be applied to those cases only in which the two wounds, existing on different parts of the body, were likely to prove immediately fatal. It must, however, be borne in mind, that all suicides do not *immediately* perish from wounds which are commonly termed mortal; on the contrary, they have often the power to perform acts of volition and locomotion, which might by some be deemed wholly incompatible with their condition. It is difficult to say whether one wound was likely to destroy life so rapidly as to render it impossible for the person to have inflicted another upon himself; but when there are several distinct incisions on the throat, each involving important bloodvessels, there is good reason to infer that they have resulted from an act of murder.

Wounds produced simultaneously, or at different times.—When several wounds are found on a dead body, the question is frequently asked,—*Which was first received?* If one is what is commonly termed mortal,

and the others not, it is probable that the latter were first inflicted. This remark applies both to cases of homicide and suicide ; but it is apparent that when, in a murderous assault, a person has been attacked by several assailants at once, the wounds may have been simultaneously produced. This is, however, a question to which it is not easy to give a specific answer. Each case must be decided from the special circumstances attending it ; and in most instances, unless some direct evidence is forthcoming, a medical opinion can be little more than conjectural. I here refer to it, because it is a question almost always put in a court of law ; and a witness should at least prepare himself to meet it by a proper examination of the medical circumstances of the case.

CHAPTER XXVI.

EVIDENCE FROM CIRCUMSTANCES.—THE POSITION OF THE BODY.—OF THE WEAPON.—EVIDENCE FROM BLOOD, HAIR, AND OTHER SUBSTANCES ON WEAPONS.—MARKS OF BLOOD ON CLOTHING AND FURNITURE, ON THE DECEASED, AND ON THE ASSAILANT.

Evidence from circumstances.—In pursuing the examination of the question respecting the homicidal or suicidal origin of wounds, the attention of the reader may be called to the force of evidence which is sometimes derived from the circumstances under which the body of a person, dead from wounds, is discovered. It may be said that this is a subject wholly foreign to the duties of a medical jurist, but I cannot agree to this statement. There are few in the profession who, when summoned to aid justice by their science in the detection of crime, do not seek for circumstances by which to support the medical evidence required of them. A practitioner would certainly be wrong to base his professional opinion on these circumstances, but it is scarcely possible for him to avoid drawing an inference from them as they fall under his observation. Care must be taken that this inference is not overstrained. The medical evidence may be of itself weak, and insufficient to support a charge against the accused ; in such a case, if any suspicious circumstances have come to his knowledge, he may be often unconsciously induced to attach greater importance to the medical facts than he is justified in doing. In short, he may, through a feeling of prejudice, which it is not always easy to avoid, give an undue force to the medical evidence. But if a proper degree of caution is used in drawing inferences, and the circumstances are not allowed to create a prejudice in his mind against the accused, a medical man is bound to observe and record them ; for, being commonly the first person called to the deceased, many facts capable of throwing an important light on the cause of death, would remain unnoticed or unknown but for his attention to them. The position of a dead body, the suddenness of death, the discovery of a deadly poison, the distance at which a knife or pistol is found—the position of the instrument—whether

situated to the right or left of the deceased—the marks of blood or wounds about the person, or of blood on the clothes or furniture of the apartment, are facts which must assist materially in developing the real nature of a case, and in giving force to a medical opinion. Many of these circumstances can fall under the notice of him only who is first called to the deceased; and, indeed, if observed by another, no advantage could be taken of them, except from the interpretation of a medical man.

At the same time, a person may have died suddenly, and a weapon or poison be found near the body, and yet the death may have taken place from natural causes. Due allowance must be made for coincidences of this kind. The purchase and possession of a deadly poison shortly before a sudden death may create suspicion, but a careful analysis may show that there is no poison in the body, and further that the post-mortem appearances are consistent with natural disease, and unless treated as exceptional in character, they are not consistent with death from poison. Mr. Stedman, of Guildford, met with a case in which a woman was found dead under very suspicious circumstances. Within half an hour of her death she had sent a boy to a shop to purchase a packet of Battle's vermin-killer (strychnia). He gave it to her and left the house. When he returned at the time mentioned, he found her leaning on the table, speechless and motionless. She was then dead. There was no rigidity and no evidence of convulsions. Some fluid was found in the stomach, but in this there was no strychnia, and none of the blue coloring matter which had been sold with the powder. No trace of the powder could be found on the premises, and no cup, glass, or vessel in which the poison might have been mixed, could be seen. ("Med. Times and Gaz.," Jan. 14, 1865, p. 34.) The absence of any characteristic symptoms, and the non-detection of the poison and its coloring ingredient under the circumstances, negatived the suspicion of poisoning. The purchase, possession, and the non-discovery of the purchased packet after the death of the woman, were circumstances which created suspicion, but nothing more. The medical facts proved that the suspicion was unfounded. The state of the lungs and heart accounted for sudden death.

Among the questions which present themselves on these occasions are the following: Is the position of a wounded body *that* which a suicide could have assumed? Is the distance of a weapon from the body such as to render it improbable that it could have been placed there by the deceased? In answering either of these questions, it is necessary to take into consideration the extent of the wound, and the time at which it probably proved fatal. Again, it may be inquired—Has the deceased bled in more places than one? Are the streams of blood all connected? Are there any marks of blood on his person or clothes which he could not well have produced himself? Are there any projecting nails or other articles which might account for wounds on the body as the result of accident? These are questions, the answers to which may materially affect the case: hence, a practitioner, in noticing and recording the circumstances involved in them, ought to exercise due caution.

The rules for investigating a case of alleged death from violence have been elsewhere described (p. 22, *ante*). Among the additional circum-

elasticity of the skin. Thus the first stab through the dress may not present any appearance of blood on the outside, but in a second stab, with the same weapon, the outside of the dress should present a bloody mark, unless the weapon had previously been wiped (p. 273). The blood may have been removed by washing, from the blade of a knife or dagger; hence the handle and inner portions, the notch for opening the blade, and the indentations of any letters stamped upon it, should be closely examined with the microscope.

The blood on a weapon may be wet or dry, in a partly coagulated state, or diffused as a mere yellowish-red film. If coagulated, this would render it probable that the blood had issued from the body of a living person or animal, or from a body recently dead. But the blood of a *dead* animal dried in small spots on the blade of a knife may sometimes present a similar appearance, and thus lead to a mistake in evidence.

4. *Hair and other substances on weapons.*—In some instances no blood may exist on a weapon, but a few hairs or fibres may be found adhering to it if the weapon is of a bruising or cutting kind. The main question may be, in such a case, whether the hair is that of a human being or of an animal, and whether the fibres correspond in their nature, form, and color to articles of dress on the deceased or the accused. In a case of murder by manual strangulation which occurred to Dr. Hofmann, so much violence had been employed by pressure with the fingers, that not only was a quantity of blood effused, but portions of cuticle with the fine downy hairs of the neck of deceased had been removed. The blood with the abraded cuticle and hairs was found upon a towel which was traced to the assailant. (Eulenberg's "Vierteljahrs.," 1873, 2, p. 112.) On a trial for murder in Ireland, Nov. 1877, it was proved that there were hairs firmly clenched in the hands of deceased; and when these were compared with a like number of the prisoner's hair they were found to correspond.

The importance of examining closely the hair found on weapons is shown by a case quoted by Dr. Lyons, in which a hatchet having clotted blood and hair adherent to it was produced as evidence against an accused person, under whose bed this weapon had been found. This, with other circumstantial evidence, had turned public opinion strongly against the prisoner; but when the hair was examined it was found not to be human, but to have been taken from the body of some animal. This circumstance led to a more complete sifting of the evidence, and the accused was acquitted. It turned out that the accused had killed an animal with the hatchet, and had carelessly thrown the weapon under the bed. ("Apology for the Microscope," p. 24.)

Before any coagulated blood is removed from a weapon, it should be examined carefully by the microscope. Hairs, or fibres of cotton, linen, wool, or silk may be found imbedded in the solidified blood, either on the edge, or on the blade; and evidence of this kind may occasionally be of great importance. In *Reg. v. Harrington* (Essex Lent Assizes, 1852), a razor was produced in evidence, with which it was alleged the throat of the deceased had been cut. I examined the edge microscopically, and separated some small fibres from a coagulum of blood, which, under a high magnifying power, turned out to be cotton fibres. It was

proved at the trial that the assassin, in cutting the throat of the deceased while lying asleep, had cut through one of the strings of her cotton night-cap. This was a strong circumstance to show that the razor produced was the weapon with which the fatal wound had been inflicted.

In *Reg. v. Steel* (Maidstone Summer Assizes, 1863), Dr. Pavy and I examined the boots of the prisoner who was charged with the murder of the deceased. The marks of violence about the head showed that the assailant had trampled on the deceased after he was on the ground, producing severe wounds, which led to his death. Some hairs were found firmly wedged beneath the large hobnails of the boots; and in certain dark stains of coagulated blood on the leather, there were some red woollen fibres. The hair was compared with a portion cut from the head of the deceased, and corresponded in color and size. On inquiry it was found that at the time of his death deceased wore round his neck a red woollen comforter, of which the wool corresponded in color and appearance with that taken from the prisoner's boots. The case was brought home to the prisoner by a variety of circumstances, all inconsistent with his innocence. I have elsewhere referred to the case of *Cass* (*Reg. v. Cass*, p. 413), in which the dried blood upon a knife lying near the body of deceased, was found on a microscopical examination to lock up within it certain fibres of woollen of a peculiar dark dye, resembling the fibres taken from a coat worn by the prisoner.

Fibres found upon weapons should, if adherent to coagula, be removed by careful digestion of the clot of blood in water, otherwise they may be at once examined in the dry state. A magnifying power of about 300 diameters may be employed. Under these circumstances *cotton* presents itself as a flattened band, assuming more or less a spiral form (Fig. 48). The fibre of *linen* derived from flax is of a rectilinear form, with jointed markings at unequal distances, the fibre tapering to a point (Fig. 49).

Silk and woollen have other characters by which they may be identified. Silk presents a regular cylindrical form, and there are no markings upon the surface. It has a strong refracting power on light, which gives to

the fibre a well defined boundary (Fig. 50). The fibre of *woollen* is irregular, contorted, of unequal thickness, and it has peculiar markings of an imbricated character on the surface (Fig. 51). This may be taken as the type of cloth, shoddy, alpaca, merino, and a variety of other fabrics worn as clothing. The hair of the head presents itself in transparent cylinders, variously colored, with markings resembling those of wool, but hair is more uniform in width. It has a cortical and medullary portion. Human hairs vary much in size—some do not exceed the $\frac{1}{16}$ th of an inch. The hairs of the eyebrows, like those of the eyelashes, are coarser and thicker than those of the head, and are opaque, except near the point, where they become transparent. In examining hairs microscopically, it will be well to observe whether they are of the same, or of

different colors or sizes, whether they are pointed at one end or cut at both ends, and whether they have still attached to them the bulb or sheath in which they grew.

Foreign substances are sometimes found in contused and lacerated wounds, which may throw a light on the mode in which they were inflicted. In gunshot wounds it is not unusual to find portions of paper or other substances used as wadding for the gun or pistol. The preservation of articles of this description, or of portions of the projectiles found under these circumstances, has proved a means of fixing the crime upon the guilty person. When a gun or pistol is discharged near to the body, a portion of the wadding is generally carried into the large irregular wound produced. In a case of stabbing, a portion of the weapon may be found in the wound.

5. *Marks of blood on clothing or furniture.*—It is proper to notice all marks of blood on the clothes of the deceased, or in the apartment, and to observe where the greatest quantity of blood has been effused; this is generally found on the spot where the deceased has died. The deceased may have bled in more places than one; if so, it is proper to notice whether there is any communication in blood between these different places. Blood on distant clothes or furniture may show whether the

deceased has moved about, and whether he has struggled much after receiving the fatal wound. Acts of locomotion by a wounded person who has died from loss of blood, or by a criminal whose hands and feet may be bloody, are generally indicated by tracks or marks of blood. The observation of these marks, if made at the time that a dead body is found, is of great importance. They may be so situated as to show that the body of the deceased has been moved, or been interfered with after death, and thus throw a light upon the question whether the act has been one of homicide or suicide. In reference to clothing, it is advisable, if it be possible, to have some clear proof that the clothes sent for examination were actually worn by the accused, or belonged to the deceased. Serious mistakes are sometimes made, and medical opinions should therefore be expressed with caution.

It should be noticed on these occasions, whether the blood is deposited in large patches on clothing, or whether it is sprinkled, and also whether it is in large or small quantity. The sprinkling may have proceeded from a wounded artery, or from a splashing of blood as a result of continued violence. We should likewise observe whether, if the wound is in the throat or chest, blood has flowed down in front of the clothes or person, or whether it has flowed so as to collect in the armpits, or on each side of the neck; for these appearances will sometimes show that the wound was inflicted when the person was standing, sitting, or lying down. If the throat is cut while a person is lying down it is obvious that the blood will be found chiefly on either side of the neck, and not extending down the front of the body. Few suicides cut the throat while in a recumbent posture, and the course which the blood has taken may, therefore, be sometimes rendered subservient to the distinction of a homicidal from a suicidal wound. The position in which the body was when a wound was inflicted, is a frequent question on inquests and criminal trials.

When spots of blood are found upon articles of dress or furniture, their *form* and *direction* may occasionally serve to furnish an indication of the position of the wounded person with respect to them. Thus, if the form of a spot is oval and elongated, the presumption is that the person was placed obliquely with respect to the stained furniture during the hemorrhage. ("Ann. d'Hyg.," 1840, p. 397.) The force with which the blood has been thrown out, will be in some measure indicated by the degree of obliquity and length of the spot. This is in general wide and rounded at the upper part, but narrow and pointed below.

6. *Marks of blood or violence on the dead body.*—In examining a dead body, attention should be paid to the state of the *mouth* and *throat*. Assailants who make their attack during sleep, sometimes endeavor to close the mouth, or to compress the throat, so as to prevent an alarm being given. In one instance there were the marks of finger-nails around the mouth; in another, ecchymosed impressions, as if produced by a hand, were found upon the throat of the deceased. The *hands* of a dead person should always be examined; many recent cuts, excoriations, or incisions found upon them, especially if on the back of the fingers or thumbs, will indicate that there has been a mortal struggle with the assailant. In the inspection, the examination of the *stomach* should not be omitted. The presence or absence of food, mucus, or

blood may furnish evidence of considerable importance in the elucidation of the case. All marks or stains of blood, or dirt, on a dead body require special observation. The impression of a hand, or of some of the fingers, may be found on the skin in a situation where it would have been improbable or impossible for the deceased to have produced it, even supposing that one or both of his hands were covered with blood. In one case of murder, there was found the bloody impression of a left hand upon the back of the *left hand* of the deceased, in such a position that it was quite impossible the deceased himself could have made the mark. In all cases it should be noticed whether the *inside* or *outside* of the hand, or whether one or both hands are stained with blood; and the size and position of the stains should be described. Marks of blood on the dress of a wounded person, or a dead body, may often furnish important circumstantial evidence. If there are several stabs or cuts on the body involving the dress, it should be observed whether the edges of one or more of them are stained with blood, as if from the wiping of a weapon, and whether the stain is on the outside or inside of the article of dress. In simulated personal injuries, the stain of blood may be, through inadvertence, applied to the outside of the dress—a fact which might, in some instances, lead to the detection of the imposture. (See case by Dr. Bayard, “*Ann. d’Hyg.*,” 1847, vol. 2, p. 219.)

7. *Marks of blood on the assailant.*—It is a very common idea that no person can commit a murder in which blood is effused, without having his person and clothes more or less covered with blood. Nothing can be more erroneous. On several occasions I have been required to examine articles of clothing which had been worn by persons subsequently convicted of murder by wounding, and either no blood has been found on any part of the dress, or only small spots wholly out of proportion to the quantity of blood which must have flowed from the deceased. (*Reg. v. Harrington*, Chelmsford Assizes, 1852. *Reg. v. Flack*, Ipswich Assizes, 1853. *Reg. v. Cass*, Carlisle Assizes, 1860. *Reg. v. Rowlands*, Beaumaris Assizes, 1861. *Reg. v. Edmonds*, Swansea Assizes, 1862.) In the case of *Gardner* (C. C. C. 1862), in which there had been a large effusion of blood from a severe wound in the throat, no blood-stains were found on the clothing of the man who was convicted of the murder. Policemen are frequently misled in searching for criminals, by looking for blood on clothing as a necessary accompaniment of an act of murder. This also leads them to magnify stains of red paint, iron-rust, and fruit-stains on the dress of an accused person into marks of blood!

It is obvious that the throat of a person, while standing, sitting, or kneeling, may be cut by a murderer from behind, and thus in appearance simulate suicide. Under these circumstances, the clothes of the assassin would escape being stained with blood. The flowing or spurting of blood upon the clothes of the assailant will depend upon his position in relation to the deceased at the time of inflicting the wound, and this must always be a matter of pure speculation. In entire violation of this simple principle, the fact of a prisoner's clothes not being marked with blood has been on more than one occasion urged as a proof of his innocence! (*Reg. v. Dalmás*, C. C. C., June, 1844.) In this case the

counsel for the prisoner wished to impress the jury, in what is commonly denominated a "powerful" speech (in which medical facts and opinions are usually ignored), that no person could cut the throat of another without having his clothes covered with blood; and as there was not proved to be any blood on his clothes, the prisoner could not have been guilty of the crime. The facts were simply that the throat of the woman was cut while she was walking across Battersea Bridge, the prisoner having inflicted the wound from behind!

Another circumstance to be noticed is that the accused may have had time to change his clothes in spite of the supposed vigilance of the police. This has occurred in several trials for murder. (*Reg. v. Heath*, Bucks Lent Assizes, 1854; *Reg. v. Cass*, Cumberland Assizes, 1860.) In one case the trousers taken from the prisoner soon after the murder presented no marks of blood; but the trousers actually worn by him were found with blood upon them pending the trial. In other instances, the prisoner may have had time to remove any stains by washing. Owing to this erroneous assumption that where much blood has been lost by the deceased, the assassin's clothes could not have escaped being "deluged" with blood, juries have been led to return verdicts of acquittal in cases in which, although no blood-stains were found, the circumstances proved were consistent only with the theory of murder.

On the trial of *Sub-Inspector Montgomery* for the murder of Mr. Glasse (Omagh Assizes, July, 1873), the absence of blood-stains on the clothing of the prisoner was alleged to be a strong proof of his innocence of the crime. In this case the wounds on the head of the deceased were of a contused kind, produced by a bill-hook. There was blood on the floor around the body, but much of this had, no doubt, flowed from the wounds after death. The wounds were not likely to have been attended with a great spurting of blood or any copious effusion at the time of their infliction, yet it was assumed that such a murder could not have been perpetrated without the clothes of the assassin being "covered" with blood. As the evidence against the accused was entirely circumstantial, much stress was laid upon this state of the clothes as a proof of his innocence. The prisoner had been previously tried twice for the crime, and the juries were not able to agree, chiefly owing to the absence of blood from his clothes. On the third trial he was convicted, and the conviction was immediately afterwards justified by an admission of his guilt. He admitted that he had removed the blood-stains from his clothes with cold water, soon after the perpetration of the crime. A case like this is surely sufficient to show the danger of trusting to such a fallacious criterion as a proof of innocence.

The counsel who defended *Courvoisier* for the murder of Lord William Russell (*Reg. v. Courvoisier*, C. C. C., 1840) contended in the strongest terms, that the accused could not have perpetrated the crime because there were no marks of blood on any of his clothes, and no bloody weapon was found in his possession or in the house. As all the vessels of the throat of the deceased had been cut to the vertebral column while he was lying asleep, it was alleged to be impossible that the assassin could have escaped from the spurting of blood from the large vessels. After his conviction the prisoner admitted that when he committed the

murder at night he wore no clothes, but was in a state of nudity, and that all he did was to wash his hands! The weapon which he employed was the carving-knife of the house, which he washed and returned to the tray with the other knives! A similar defence was raised in *Reg. v. Thompson* (Durham Winter Assizes, 1863), in which the prisoner was charged with the murder of his wife, by cutting her throat with a razor. According to the medical evidence, the wound in the woman's throat was five inches in length, and in a direction from left to right, extending from the angle of the left jaw to an inch behind the right ear, dividing all the bloodvessels and nerves of the throat. The medical witness properly stated that such a wound could not have been self-inflicted. It proved rapidly fatal. No razor or other weapon that could have produced the wound was found near the body. The prisoner stated that the wounds had been produced on herself by deceased during a struggle. No blood was found on the prisoner's clothing, and on this fact the counsel for the defence mainly relied to show that this was not an act of murder, but of self-destruction. The man was convicted, and the case here quoted proved, that the defence was based on a pure fallacy. ("Times" of Wednesday, Dec. 17, 1873.)

The presence of spots of blood on articles of clothing, knives, etc., taken from the persons of those who are accused of murder, may be quite consistent with innocence. Small spots or stains have often an undue importance attached to them. I have known minute spots of blood on the shirt of a man tried for murder by wounding, regarded as furnishing proof of criminality, until it was explained that they were probably derived from flea-bites, and that some were on one side and some on the other, showing that the shirt had been worn on the two sides. The coarse clothing worn by laborers may acquire blood-spots from a variety of accidental circumstances, which the accused may not always be able to explain. When he knows the stains are there, and manifests great anxiety to give some explanation of their presence, as by falsely stating that he had assisted in killing a pig, a rabbit, or that he was carrying game about him,—there may be strong ground for suspicion; but a medical practitioner should always make due allowance for the accidental presence of blood on the clothes of workingmen.

In a case of suicide (October, 1872) by cutting the throat, the son who first discovered his father lying dead imagined that he had broken a bloodvessel. The son lifted up the body, and then went for assistance. In this way his hands and clothes became bloody. At the inquest he was closely questioned on this point. There could not be the least doubt that the act was one of suicide, and that the clothes of the son had become accidentally covered with blood in the manner in which he stated.

CHAPTER XXVII.

CHEMICAL EXAMINATION OF BLOOD-STAINS.—STAINS OF BLOOD ON LINEN AND OTHER STUFFS.—AGE OR DATE OF THE STAINS.—OTHER STAINS RESEMBLING BLOOD.—BLOOD ON WEAPONS.—ARTERIAL AND VENOUS BLOOD.—VARIETIES OF BLOOD.—BLOOD OF MAN AND ANIMALS.—MICROSCOPICAL EVIDENCE.

Examination of Blood-stains.—It may appear at first sight an easy matter to say whether certain suspected spots or stains on articles of clothing, furniture or weapons are or are not owing to blood; but in practice, great difficulty is often experienced in answering the question. If the stains are large and recent, most persons may be competent to form an opinion; but the physical characters of blood are soon changed, even when the stuff is white and otherwise favorable for an examination. If the stains, whether recent or of old standing, are upon dark-dyed woollen stuffs, as blue, black, or brown cloth, or if they appear in the form of small or detached spots, or in thin films on dark clothing or rusty weapons, no one but a competent medical man should be allowed to give an opinion.

Chemical analysis.—There is no direct chemical process by which blood can be identified, but we presumptively establish its nature by determining the presence and properties of the red coloring matter, or *hæmatine*. The chemical properties of the red coloring matter of blood are as follows: 1. It readily combines with cold water, forming, if recent, a bright red solution. 2. The red color of this solution is not changed to a crimson or a green tint by a few drops of a weak solution of *ammonia*. If the ammonia is concentrated, or added in large quantity, the red liquid will acquire a brownish tint. 3. The red liquid when *boiled* is coagulated—the color is entirely destroyed, and a muddy-brown flocculent precipitate is formed, the quantity of which will depend on the quantity of coloring matter and albumen present. The red coloring matter of blood is always more or less mixed with albumen, and it is this principle which gives to a dried blood-stain on linen or cloth a well-marked stiffness, and a glossy surface. Stains from cochineal and the red colors of wine, flowers, and fruit, are dull, and do not cause any stiffening of the fibre of the stained stuff, nor any appearance under the microscope at all resembling a dried coagulum of blood. 4. A solution of the red coloring matter of blood in water produces, with freshly made tincture of *guaiacum*, a reddish-white precipitate of the resin. On adding to this an ethereal solution of *peroxide of hydrogen*, a beautiful blue color is more or less rapidly brought out. If a sufficient quantity of alcohol or ether is added,

the precipitate will be dissolved and a deep sapphire blue solution will result. Cochineal and other red coloring matters when thus treated, give a reddish color to the resin of the tincture of guaiacum, and undergo no change on the addition of peroxide of hydrogen. They are thus well marked and distinguished from the red color of blood. Whether the blood is new or old, whether concentrated or exceedingly diluted, this test produces the blue coloration. It produces the change better in a diluted than in a concentrated state. A drop of blood diffused through six ounces of water may be thus detected in one or two drachms of the mixture. Such are the chemical properties of blood, whether taken from the human body or from that of any warm red-blooded animal (mammalia).

Of the various red coloring matters extracted from vegetable and animal substances, there are none which to the experienced eye present the peculiar crimson red tint of blood, especially when the substance is examined in a good light by a low power of the microscope. When solutions of these red coloring matters are treated with ammonia, some, such as cochineal, logwood, and the colors of roots and woods, acquire a deep crimson tint, while others, such as the coloring matter of the rose and the red colors of flowers and fruits, are changed to a blue or green. The red colors are not destroyed by a boiling temperature, and even when mixed with albumen, this principle is simply coagulated, while the red coloring matter remains unchanged. In the case of blood, the effect of heat is to destroy the color entirely. When these vegetable colors are found upon linen and similar stuffs, they present under the microscope the appearance of a uniform stain or dye, unlike blood in color. There is no glossy coagulum to be seen, and the stained stuff is not stiffened as it is by the serum of dried blood.

Stains of blood on linen and other stuffs. Their age or date.—Supposing the stuff to be white, or nearly colorless, the spot of blood, if recent, is of a bright red color; but by exposure it sooner or later becomes of a reddish-brown, or of a deep red-brown color. This change of color to a reddish-brown I have found to take place in warm weather in less than twenty-four hours. After a period of five or six days, it is scarcely possible to determine, from the appearance, the *date* of a stain even conjecturally. In a large stain of blood on linen, no change took place during a period of five years; it had a reddish-brown color at the end of six weeks, which it retained for the long period mentioned. Indeed, it is extremely difficult in any case, after the lapse of a week, to give an opinion as to the actual date of a stain. Upon colored stuffs or dirty clothes, it is, of course, impossible to trace these physical changes in stains of blood—on red-dyed stuffs the stain appears simply darker from the first, and in all cases the fibre of the stuff is more or less *stiffened*, as a result of the drying of the albumen associated with the red coloring matter. In examining an article of clothing, attention should be paid to the side of the stuff which has first received the stain; sometimes both sides are stained. The evidence derived from an observation of this kind may be occasionally of importance. An important case, involving the date of blood-stains on a towel, is reported by Dr. Hofmann. (Eulenberg's "Vierteljahrschrift," 1873, v. 2, p. 89.)

The suspected stain should be first examined in a strong light, with a low power of the microscope. If caused by blood, it will not be a mere coloring of the fibres, but it will have a shining glossy appearance, and each fibre will be observed to be invested with a portion of dried coagulum or clot. In other cases, minute coagula or clots, presenting the appearance of dried red jelly, will be seen in the meshes of the stained article of clothing. In certain lights the clots may appear of a dark-red color, but by changing the light, bright translucent portions of a peculiar crimson tint will come into view. The crimson stain of blood is unlike that of any other red coloring matter, and when the stained portion presents the character of a glossy dry coagulum, the stain cannot be easily mistaken by a practised eye for one caused by any other red-colored liquid. In fact, the microscope puts the observer of a minute stain in the same position as a non-professional person, who unhesitatingly forms his judgment from a large quantity of dried blood. Portions of kino over a dress may present occasionally the appearance of coagulated blood, but kino differs in color and in chemical properties from blood. The microscopical observation of a suspected stain on linen, cotton, or woollen, however small, is generally sufficient to enable an expert to form an opinion either in the affirmative or negative. The application of chemical tests may be resorted to for confirmatory evidence, when there is any doubt in the mind of the observer.

Analysis.—If the quantity of blood is small, the stained substance may be cut up and macerated in a porcelain capsule, with just enough water to keep it well moistened. After an hour it may be pressed, and a red-colored liquid, in a state for testing, will be thus obtained. It may be objected that red stains resembling blood are occasionally found on linen and other stuffs, and may give rise to error. All such stains are either entirely insoluble in water, or they are soluble and yield red-colored liquids. If *insoluble*, they cannot be mistaken for blood-stains; if *soluble*, no mistake can arise, provided the red liquid so obtained is submitted to the chemical tests above described. Blood-stains rendered insoluble in water by heat or some other cause must be tested by another method. When the stain is of *old date*, a solution in water is very slowly obtained, and it does not present the bright red color of blood. In some cases if the stain is of very old standing, and has been much exposed to the atmosphere, water will have scarcely any solvent effect upon it, and it may be found impossible to obtain a red-colored liquid even after twenty-four hours' maceration. At the most, the water may acquire a pale-brown or yellowish color, but wholly unlike that imparted by blood. In such a case it is useless to add ammonia. We may, however, generally form a correct judgment by the microscopical appearance of the stain before wetting it, and by the guaiacum process. Water may dissolve sufficient albumen (or serum) to become opaline by *heat*, or by the addition of nitric acid, although we may fail to obtain any evidence by the presence of corpuscles. From the results obtained by spectral analysis it appears probable that acid and other vapors in the atmosphere affect blood-stains and alter their chemical properties. Where much coal is burnt, sulphurous acid may operate in this manner. Under other circumstances, when the quantity of blood effused is moderately

large, it may be detected by the process above mentioned, after the lapse of a considerable time. I have thus detected the blood of the human body and of the bullock on cotton, linen, and flannel, after a lapse of *three years*. If the stuff is dyed, we should proceed to examine the stains found upon it by a similar process. The dye is commonly fixed, and is not soluble in water. Thus, then, in testing for blood we rely upon: 1. The solubility of the red coloring matter in water. 2. The negative action of ammonia. 3. The positive effect of heat in entirely coagulating and destroying the red coloring matter, and 4. The blue color produced by guaiacum in the presence of peroxide of hydrogen.

There are red stains bearing a resemblance to blood, which are *insoluble* in water. These may be identified by their special characters. Among them are: 1. Certain *red dyes*, as madder, which, when fixed by a mordant, is not readily affected by ammonia. 2. *Iron-moulds*. These are of a reddish-brown color, sometimes of a bright or orange red; they are quite insoluble in water, but are easily dissolved by maceration in diluted hydrochloric acid, and on adding ferrocyanide of potassium to the solution, the presence of iron will be at once proved by the production of Prussian blue. The acid used for this purpose should contain no iron. Iron-moulds are generally distinguished by their brown color, and by the absence of all stiffening or glossiness of the fibre in the stained spot. 3. *Red paint*. Stains made with red paint containing peroxide of iron have been mistaken for blood. They may be easily identified by digesting them in diluted hydrochloric acid, and applying to the solution the tests for iron. Like those produced by iron-moulds, they are quite insoluble in water, and therefore cannot be confounded with blood-stains. The same may be said of spots of the ammonio nitrate of silver changed by light, which I have known to be mistaken for old stains of blood. The stuff on which the spots of blood are found may be itself stained with a red dye or color, or it may be dyed with iron; in this case it will be necessary to test by the same process a piece of the colored or stained portion, in order to furnish negative evidence that the suspected stains are due to blood. 4. Among *soluble* stains resembling those of blood in color, are the spots produced by the juices of the *mulberry*, *currant*, *gooseberry*, and other *red fruits*. They may be sometimes recognized chemically, by dropping on them a weak solution of ammonia, when the spot is turned either of a bluish olive-green or green color. The red of cochineal is changed into a crimson on the addition of *weak* ammonia; but a spot of blood treated with this alkali undergoes no change of color. Diluted acids brighten the red colors of fruit-stains, but they do not alter the color of blood. A strong solution of chlorine bleaches the red colors from fruit-stains, but when applied to a stain of blood it turns the red coloring matter of a dark olive-green tint and does not bleach it. Finally they are not colored blue by tincture of guaiacum and peroxide of hydrogen.

These changes of color are only well observed on colorless stuffs. If the stain is on black cloth, the color may be extracted by water and tested, or the following plan may be adopted: The stain is wetted with distilled water, and after a time several layers of white blotting paper are firmly pressed upon it. The red color, if present, is thus transferred

to the paper, and may be tested by fresh tincture of guaiacum and peroxide of hydrogen. If the guaiacum alone is blued by contact, some other method of corroboration must be adopted, since the red color of blood has no action on this resin until after the addition of peroxide of hydrogen. If no red or reddish-brown color is transmitted to the paper, or if the stain on paper produces no blue color with a mixture of guaiacum and peroxide, it cannot be owing to blood. With ordinary precautions the guaiacum process may be safely used, and by the aid of it, stains which have been *washed* for the purpose of obliteration may be detected, so long as the slightest indication of red color remains in the washed fabric. It will even give the reactions for blood upon calico or linen which has been so thoroughly washed as to appear almost colorless. The action of this test does not appear to be affected by lapse of time. A towel stained with human blood was examined in November, 1857. The stains were then recent, and had the well-marked reddish tint indicative of recent blood. In December, 1867, the spots on the towel were again examined—they had changed to a dingy brown color—they produced the usual reaction with guaiacum and peroxide of hydrogen. After the lapse of twelve years more (February, 1879), the stains had a dull dingy brown color, thick at the margin, and presenting there only a few glossy-looking particles. Guaiacum, which alone had no effect, slowly brought out with peroxide of hydrogen a beautiful blue coloration. The appearance of the stains, the towel having been loosely exposed in a drawer, had scarcely changed over a period of twenty-two years, and the guaiacum acted clearly after twelve years.

In order to guard against any fallacy, an *unstained* portion of calico, linen, paper, or cloth should be first tested. In any case a negative result will fully justify the opinion that there have been no blood-stains washed out of the stuff. The great use of the guaiacum process is in enabling the operator to distinguish the *red* coloring matter of blood from all other *red* coloring matters. And here it may be remarked that some medical jurists have strangely misapprehended its use. Other liquids not of a red color, such as seminal fluid, sweat, boiled milk, etc., are said to be affected by the guaiacum process like blood; but as these liquids are colorless, they can hardly be mistaken for blood, and, therefore, the action of guaiacum upon them is of little importance. It is not, however, in accordance with my experience that sweat or seminal fluid produces a blue color with guaiacum.

Removal of blood-stains. Examination of washed stains.—An attempt may have been made to wash out blood-stains, so that the color may be more or less changed, and no chemical evidence obtainable. There is a common notion that certain chemical agents will remove or destroy these stains; but this is not the case; the color may be altered, but when dried on the stuff it is not easily discharged or bleached. Chlorine, a most powerful decolorizing agent, turns the coloring matter of blood of a green-brown color. Hypochlorous acid has a similar effect. This acid has been recommended as useful by its bleaching properties for distinguishing the stain of blood from all other stains, excepting those produced by iron-rust. Orfila has, however, shown that it is not fitted for such a purpose, and that there are no better methods of

testing than those above described. ("Ann. d'Hyg.," 1845, 2, 112.) I have found that nothing removes a blood-stain, whether wet or dry, so effectually as simple maceration in *cold* water, although, when the stain is old, the process is sometimes slow. *Washed stains* may now be readily detected by means of guaiacum, provided they are on a colorless article of clothing. A drop of the tincture is poured on the stuff, and if there is no change of color, peroxide of hydrogen is added. The blue color appears immediately, and becomes more intense by the evaporation of the ether, or on the addition of alcohol to dissolve the white resin.

On an important trial for murder, at the Shrewsbury Lent Assizes, 1841 (*Reg. v. Misters*), this question as to the power of certain chemical reagents in discharging stains of blood was raised. Alum was traced to the possession of the prisoner; it was found dissolved in a vessel in his bedroom, and it was supposed that he had removed the blood-stains from his shirt by the use of this salt. Two medical witnesses deposed that they had made experiments, and had found that alum would take the stains of blood out of linen; according to one sooner than soap and water. The results of my experiments do not correspond with these. I have not found that alum removes stains of blood so readily as common water; and when alum is added to a solution of hæmatine in water, so far from the color being discharged, it is slowly converted to a deep greenish-brown liquid. In one experiment, a slip of linen having upon it a stain of dried blood of old standing, was left in a solution of alum for twenty-four hours, but not a particle of the red coloring matter had been extracted, although it was changed in color. The effect of yellow soap, as well as of potash, soda, and their carbonates, is to change the red color of blood to a deep greenish-brown, like many other reagents, but they do not exert on it any discharging or bleaching power.

Detection of blood on weapons.—A knife, dagger, or sword may have been used for inflicting a wound, and may have no stain upon it, or only a slight yellowish film of dried serum. It may in fact have been wiped by drawing it through the wound or clothes. In other cases the weapon may have well-marked stains upon it, and when these are recent, and on a clean or polished surface, they may be easily recognized; but when of old standing, or on a rusty piece of metal, it is a matter of some difficulty to distinguish them from the stains produced by rust or other causes. If the stain is large and dry, a portion may be scraped off, and placed in a watch-glass with some distilled water—the solution filtered to separate any oxide of iron, and then tested. If the water by simple maceration does not acquire a red or red-brown color, the stain is probably *not* due to blood. If it acquires a red color, the solution may be tested by the methods described at p. 296. Sometimes the stain appears on a dagger or knife either in the form of a thin yellowish or reddish film, or in rusty streaks. The dry matter is scraped into a small porcelain dish and a little water poured on it. If a red-colored solution is obtained, this may be poured off and tested for blood. The residue, brought to dryness, may be treated with guaiacum and peroxide of hydrogen. The particles of blood are thus distinguished from those of iron rust by the small zones of blue color formed around them. The rust is not thus affected. There is a remarkable resemblance to the stains of blood on

metal, produced by the *oxide* or *certain vegetable salts of iron*. If the juice or pulp of lemon or orange is spread upon a steel blade, and is exposed to the air for a few days, the resemblance to blood produced by the formation of *citrate of iron* is occasionally so strong that I have known well-informed surgeons to be completely deceived; they have pronounced the spurious stain to be blood. These stains, which owe their color to *citrate of iron*, may be thus distinguished: The substance is soluble in water, forming, when filtered, a yellowish-brown solution, totally different from the red color of blood under the same circumstances. The solution undergoes no change of color on the addition of ammonia. It is unchanged in color, but may be partially coagulated at a boiling temperature, and it is at once identified as a soluble salt of iron by giving a blue color with the ferrocyanide of potassium.

It is not always easy to distinguish by sight a stain of blood on a weapon from a mark produced by *iron-rust*. When strong suspicion exists, marks are often pronounced to be due to blood, which, under other circumstances, would have passed unnoticed. One source of difficulty is this: the iron-rust on an old knife may be mixed with some article of food, or even with blood itself. We must here pursue the mode of examination above described to distinguish the rust from blood (p. 298). From the foregoing remarks, we may justly infer that the chemical analysis of suspected spots or stains on weapons and clothing is by no means an unimportant duty. If we cannot always obtain from these experiments affirmative evidence, they often furnish good negative proof, and thus tend to remove unjust suspicions against accused persons.

Arterial and venous blood.—It is not possible to distinguish *arterial* from *venous* blood by any physical or chemical characters, when it has been for some days effused, and is in a dry state upon articles of dress or furniture; but this, in medico-legal practice, is not often a subject of much importance, since there are few cases of severe wounds, either in the throat or other parts of the body, in which the two kinds of blood do not escape simultaneously. The most striking and apparent difference between them, when recently effused, is the *color*,—the arterial being of a bright scarlet, while the venous is of a dark red hue; but it is well known that the latter, when exposed to air for a short time, acquires a florid red or arterial color; and the kinds of blood, when dried, cannot be distinguished chemically by any known criterion. If the coat, or other stuff, stained with blood, were of a dark color, the liquid would be absorbed, and speedily lose its physical characters. Arterial blood contains more fibrin than venous, and coagulates more firmly. The microscope shows no appreciable difference in the blood-corpuscles, and chemistry does not enable us to apply any test so as to make a satisfactory distinction between them. In this deficiency of microscopical and chemical evidence, an attempt has been made to establish a distinction by noticing the physical appearance of the blood-stains. Thus, it is alleged, the arterial blood will be indicated by its being *sprinkled* over surfaces upon which it has fallen, while the venous blood is always poured out in a full stream. In most wounds which prove fatal by hemorrhage, the blood is poured out simultaneously from arteries and veins. The sprinkled appearance of the blood, when it exists, will, *cæteris paribus*,

create a strong presumption that it was poured out from a *living* body—for after the heart has ceased to act, the arteries lose the power of throwing out the blood in jets. The sprinkling is usually observed when the wounded artery is small, and the blood is effused at a distance. This is a fact which a medical jurist should not overlook, although, for the reasons stated, too great a reliance must not be placed on it. The spots of blood, if thrown out from a living bloodvessel, speedily consolidate, and the fibrin, with the greater portion of the coloring matter, is found of a deep red color at the lower part of the spot, the upper portion being of a pale red. The lower and thicker part has commonly a shining lustre, as if gummed, when the spot is recent, and when it has been effused upon a non-absorbent surface.

When blood falls upon porous articles of clothing, it is often absorbed, and produces dull stains. In dark-colored articles of dress, it is sometimes difficult by daylight to perceive these stains. The part appears stiffened, and has a dull red-brown color, which is sometimes more perceptible when seen by the reflection of the light of a candle. In trusting to the coagulation of the sprinkled blood as evidence of its escape from a living vessel, it must be remembered that three hours may elapse before it coagulates in the healthy body after death. Hence, blood which has escaped from a recently dead body, although it would not be found diffused as if by spurting, might, in so far as coagulation is concerned, assume the appearance of having been effused from a living body.

In spite of the great advances made in the construction and use of the microscope, there is no method known by which the blood of a man can be distinguished from that of a woman, or the blood of a child from that of an adult. The blood of a child at birth contains less fibrin, and forms a thinner and softer coagulum than that of the adult. A medico-legal question has arisen, on more than one occasion, whether there were any means of distinguishing *menstrual* blood from that of the body generally. This liquid contains fibrin, although the proportion is less than in venous or arterial blood, red coloring matter, and the other constituents of blood. The only differences noticed are of an accidental kind: 1st, that it is acid, owing to its admixture with vaginal mucus; and 2d, that under the microscope it is mixed with epithelial scales, which it has derived from the mucous membrane in its passage through the vagina. (Donné, "Cours de Microscopie," p. 139.) In the bodies of women who had died suddenly while menstruating, Dr. Webber found coagulated blood upon the uterine mucous membrane. If, therefore, menstrual blood does not coagulate, it is simply because it has already coagulated within the uterine cavity, and cannot do so again; it is more fluid than ordinary blood, because, during its trickling descent, it becomes mixed with watery, uterine, and vaginal mucus. ("Schmidt's Jahrb.," 1847, 7, 139.) A case occurred in France, which induced the Minister of Justice to refer the consideration of this question to the Academy of Medicine. The reporters, MM. Adelon, Moreau, and Le Canu, came to the conclusion that there were no means of distinguishing menstrual blood dried on clothing from that which might be met with in a case of infanticide or abortion. ("Ann. d'Hyg.," 1846, 1, 181.)

The guaiacum process.—Dr. John Day, of Geelong, Australia, was the first to demonstrate by numerous experiments the proper mode of employing the guaiacum test. (“Australian Med. Journ.,” May, 1867, and Nov. 1869.) Schönbein had already discovered that the resin was blued by blood in the presence of a principle which he called antozone (which had no action on the resin), and this principle was soluble in ether. His theory was that antozone in contact with blood was changed into ozone, and blued the resin; but whether this theory be or be not correct, the facts remain—1, that the red coloring matter of blood produces no change in tincture of guaiacum; 2, that it undergoes no change of color when mixed with pure peroxide of hydrogen dissolved in ether (antozone); 3, that in the presence of those two solutions the red coloring matter of blood immediately renders the guaiacum resin blue; 4, that no red coloring matter, animal or vegetable, excepting the reds of blood (hæmatine), has been found to produce this blue coloration of guaiacum in the presence of peroxide of hydrogen.

It may be here observed that the alcoholic solution of guaiacum resin should be fresh made from the inner or unoxidized portions of resin, and the solution kept in the dark. The pure ethereal solution of peroxide of hydrogen is procurable under the erroneous name of *ozonized ether*.

M. Lefort has objected to this process on the ground that the resin of guaiacum is blued by an “unlimited” number of substances (“avec un nombre presque illimité de substances appartenant aux trois règnes de la nature,” “Ann. d’Hygiène,” 1870, 2, 432); but this objection is irrelevant and misleading. Schönbein and Dr. Day have both proved clearly that the coloring matter of blood does not cause a bluing of guaiacum resin, and therefore it could not possibly be mistaken for any one of the “unlimited” number of substances, having nothing in common with blood, which change the color of this resin. It is always proper in practice to employ the guaiacum first. If this is blued, then other methods of detecting blood should be resorted to. Out of a large number of cases, I have not met with one instance during six years in which this bluing of the guaiacum by direct contact formed any obstacle to the detection of blood.

The same remarks apply to the coloring matter of bile, which, according to Dr. Jamieson (“Australian Med. Journ.,” Oct. 1869), produces a bluing of the guaiacum resin in contact with peroxide of hydrogen. In practice, stains of bile are so strongly marked by their peculiar color, that no one competent to undertake such investigations could fall into an error of confounding these with blood-stains. The mistakes which have arisen respecting blood on clothes have been chiefly traceable to the presence of stains derived from red fruits and flowers, artificial red dyes, and some red mineral substances, such as red oxide of iron. M. Lefort states that stains produced by the red coloring matter of wine gave a blue color on the addition of a mixture of guaiacum and peroxide, but this was only after *some hours’ exposure*! (Op. cit. p. 438.) It is the very essence of this mode of testing, that the effect in blood is immediate, or that it takes place within a few seconds. No reliance can or ought to be placed upon any change of color which requires hours for its production, since the resin alone, or in mixture with peroxide, is slowly

blued under long exposure to air. If this mode of testing were followed, the results would be in all cases fallacious.

The test operates equally well on fresh and old blood, and on concentrated as well as very diluted blood, even on blood which has been boiled. In conjunction with the spectroscope, it is the only certain method of discovering washed blood (*vide infra*). Provided some small portion of red coloring matter remains, the change to blue is perceptible. If the stain on the material gave no indication of color—whatever might be the effect of this or any other tests—it would be unsafe to affirm that blood was present. On the other hand, the proper precautions being observed in the use of this test, if there is no bluing of the guaiacum resin in the presence of peroxide, it will be safe to say that the mark or stain is not owing to blood. Every prudent witness would avoid relying upon one test, and therefore, as so small a quantity of blood is required for the action of guaiacum, it will be always easy to reserve a portion for the spectroscope and other chemical tests, so that not even a shadow of an objection should be raised against the results.

Microscopical evidence. Blood-corpuscles.—Hitherto the microscope has been referred to as an aid to the examiner in drawing a distinction between the appearances presented by blood-stains in the dry state, and those caused by other substances (p. 297). Its use, however, extends much beyond this. The spots or stains may be so small as not to admit of removal, for the purpose of applying chemical tests. If an examination of the dry stain with a low power (20 or 30 diameters) justifies further proceedings, we may then employ the microscope for the purpose of detecting those peculiar bodies or corpuscles on which the color of red blood is known to depend.

Fig. 54.
Blood-corpuscle, highly magnified.

The red coloring matter of blood consists of minute colored cells or corpuscles, floating in a clear liquid (serum). The engraving (Fig. 54) shows the form which the corpuscle presents in the class mammalia. *a* represents the circular form, when seen in front, the shaded portion being a depression which under a certain disposition of the light assumes the appearance of a solid and opaque nucleus; *b* represents the corpuscle seen edgewise, in which case it presents somewhat the outline of a biconcave lens. It owes this form to the central depression on each face. Other red coloring matters, such as madder, cochineal, or lac, do not owe their color to independent cells or corpuscles. Hence, if corpuscles, of the form and size of those found in mammalian blood, are visible under the microscope, there can be no doubt that the liquid is blood. Such evidence can, however, be safely received only from one who has been accustomed to the use of this instrument, and to the examination of blood. In order to examine the suspected substance for corpuscles, the best plan of proceeding, when the particles of coagulum are very small, is to breathe several times on a glass slide, then place the small fragments of coagulum on the slide, and again breathe over them. A slip of thin glass may then be laid upon them. If they consist of blood a red margin will soon appear, and in the fluid portion, by the aid of a magnifying power of from 300 to 500 diameters, some of

the corpuscles of the blood may be recognized. They are seldom as perfectly spherical as in the fresh state, and they appear small, and frequently shrunk or corrugated. In some cases, only fragments of the envelopes can be seen. The condensed moisture of the breath may serve the purpose of water, in breaking up the small portions of dried blood, without destroying the corpuscles by too much dilution, but in general the addition of a small quantity of water with glycerine is necessary.

If the suspected clot is in larger quantity, it may be removed from the stuff and placed to macerate in one or two drops of water on a glass slide. It should be covered with thin glass, in order to prevent rapid evaporation. This method of extracting the corpuscles has frequently failed, owing to the quantity of water employed having been too large. Under these circumstances, the corpuscles are distended, become of a globular form, paler, and are finally destroyed, while the water simply becomes colored. It is by no means easy in all cases to obtain from dry coagula, clear and distinct evidence of the presence of these corpuscles, especially when the blood is old. In drying, the blood-cells lose their form, and they do not readily assume it when again moistened. Unless they are seen after a short maceration in a very small quantity of water, it is probable they will not be seen at all. To accelerate their separation various chemical liquids have been recommended. Thus strong solutions of sulphate of soda, chloride of sodium, and iodide of potassium, have been employed as fluid media for breaking up the dried clots of blood. There are some disadvantages attending the use of these saline solutions. A mixture of glycerine and water may be employed in place of them. The most convenient proportions are, one part by measure of glycerine, to three parts by measure of distilled water. A solution of arsenious acid, in the proportion of four grains to an ounce of distilled water, as recommended by Dr. Kunze, is also a rapid solvent of the coagula. When this is used, the examination should take place as soon as the liquid begins to be colored at the margin, or the corpuscles may be destroyed, and only fragments of their envelopes seen.

In reference to stains on clothing, if they present any appearance of dry coagula, these should be carefully scraped off, and treated in the manner above described. If no portions of solid coagula can be procured, there will be but little hope of obtaining evidence of the presence of corpuscles in the suspected stain. The stained portion may be cut out and macerated in a small quantity of water. Under these circumstances, the corpuscles may be sometimes seen aggregated, or in groups, in the fibres of the stuff, as in the subjoined engraving (Fig. 55), in which the stain of blood was on a shirt. (Briand's "Manuel de Méd. Lég.," p. 747, 1863.)

The annexed illustrations (Figs. 56 and 57) show the appearances presented by blood-corpuscles, when examined by a power of about 300 diameters, and under different methods of treatment. Fig. 56 represents the appearance of a drop of healthy human blood. The red blood-cells are partly detached, partly united in rolls, and partly in irregular clus-

Fig. 55.

a. Corpuscles of blood in linen fibre. b. A group detached.

ters. In the vacant spaces between them there are delicate threads of fibrin. The outlines of the blood-cells are rendered, in some instances, indistinct, by reason of this web of fibrin above them.

Fig. 56.

Human blood-corpuscles with fibrin.

Fig. 57.

Human blood-corpuscles from a dried specimen, magnified 319 diameters.

In Fig 57 the corpuscles are seen free from fibrin, and in groups (a) as well as singly. Only a small portion of those which were in the field have been engraved. The shaded bodies (b) are the white corpuscles of the blood; they are larger but less numerous, not so well defined in form, and they present an irregularity of surface, by which they may be distinguished from the colored blood-cells.

Some practice in the use of the microscope is required to enable a medical man to arrive at a correct conclusion in these investigations. Granules of starch and the spores of vegetables might be mistaken for blood-corpuscles. Erdmann states that in examining some articles of clothing in a case of suspected murder, he thought he had detected blood-globules in the liquid which he procured, but he found on further inspection that they consisted of the red-colored spores of an alga known as the *porphyridium cruentum*. ("Ed. Med. Journal," Oct. 1862, p. 370.) The size of the bodies as well as their shape will sometimes aid the observer. The blood-corpuscles have a definite size: the bodies seen under the microscope may be either too large or too small to fall within the exceptional range of size. Hence the micrometer is a necessary adjunct to the instrument. Granules of starch would be identified by the blue color imparted by iodine.

Blood of man and animals.—When marks of blood have been detected on the dress of an accused person, it is by no means unusual to find these marks accounted for by his having been engaged in killing a pig, bullock, or sheep, or in handling fish or dead game. Of course every allowance must be made for a statement like this, which can be proved or disproved only by circumstances; but the question here arises whether we possess any *certain* means of distinguishing the blood of a human being from that of an animal.

Some years since, M. Barruel and other French medical jurists affirmed that by mixing fresh blood with one-third or one-half of its bulk of strong sulphuric acid, and agitating the mixture with a glass rod, a *peculiar*

odor was evolved, which differed in the blood of man and animals, and also in the blood of the sexes. This odor, it was said, resembled that of the cutaneous exhalation of the animal, the blood of which was made the subject of experiment. (See Devergie, "Méd. Lég.," vol. 2, p. 907.) It is true that strong sulphuric acid does give rise to a particular odor when mixed with fresh blood, probably owing to its decomposing action on some of the animal principles: and it is possible that some persons may discover a difference in the odor, if not according to the sex, at least according to the animal. But assuming this to be true, there is probably not one individual among a thousand whose sense of smelling would allow him to state, with undeniable certainty, from what animal the unknown blood had really been taken. In a case of some importance, which occurred in Paris, the testing of blood by odor completely failed in the hands of M. Barruel and two other eminent French medical jurists, MM. Tardieu and Chevalier. The mistakes made by these experts are admitted by themselves to have been of so serious a nature as to render this mode of obtaining evidence in any future case inadmissible. ("Annales d'Hyg.," 1853, 1, 413.) For additional remarks on this subject, see paper in "Guy's Hospital Reports," Oct. 1851.

There are no *chemical* differences between the blood of man and animals. The red coloring matter, the albumen and fibrin, are the same, and chemical reagents produce on them precisely similar results. The microscopical differences refer to the *shape* and *size* of the corpuscles. 1. With respect to *shape*. In all animals with red blood, the globules have a disk-like or flattened form. In the mammalia, excepting the camel tribe, the outline of the disk is *circular* (Fig. 54, *a*, p. 304.) In this tribe, and in birds, fishes, and reptiles, the corpuscles have the form of a lengthened ellipse or *oval*. In the three last-mentioned classes of animals they have a central nucleus, which gives to them an apparent prominence in the centre. In applying the guaiacum process to this variety of blood, it is found that the nucleus acquires a deep blue color, while the oval margin or envelope is of a violet tint. In mammalian blood the round corpuscle acquires a uniformly blue color. ("Amer. Jour. Med. Sci.," Jan. 1874, p. 128.) The blood corpuscles of all the mammalia, including those of the camel tribe, have no central nucleus, and they appear depressed in the centre. The microscope therefore enables an observer to distinguish the blood of birds, fishes, and reptiles from that of a human being or from mammalian blood; and this may be of great importance as evidence.

In the case of *Reg. v. Libbey*, a case of child-murder tried at the Cornwall Summer Assizes, 1871, the prisoner, who was indicted for the murder of her child, alleged that some blood found on certain articles of clothing was fowl's blood; but Mr. Hudson, the medical witness, was able to prove that this statement was untrue. He examined the stains by the microscope, and found that the corpuscles had not the oval form of those in the blood of a bird; but he was unable to say whether they were human or animal. Again, in *Reg. v. Ward* (Leeds Summer Assizes, 1878), in which case the prisoner was charged with murder, a patch of blood was found upon his trousers, obviously of recent date. When asked to account for this, he said it was owing to the blood of a fowl. A

microscopical examination of the blood was made, and it was then seen that the blood-globules had the form and characters of those of a mammal and not of a bird. This proved the falsehood of the defence.

The chief microscopical distinction between the *blood of man and domestic animals*, consists in a minute difference in the *diameter* of the corpuscles. This, however, is only an average difference; for the corpuscles are found of different sizes in the blood of the same animal. In making use of this criterion, it would be necessary to rely upon the size of the majority of the corpuscles seen in a given area, and under the same power of the microscope. It is a curious fact that their size bears no relation to the size of the animal. Thus, in the horse, ox, ass, cat, mouse, pig, and bat, they are, on an average, nearly of the same size; the difference is so slight as to be practically inappreciable. In these animals they are smaller than in man and in several of the mammalia. The corpuscles in man, the dog, the rabbit, and the hare, are of nearly the same size. In the blood of the sheep and goat, they are much smaller than in other mammalia, while in man they are larger than in any of the domestic mammalia. The size of the corpuscles bears no proportion to the *age* of the animal: thus in the blood of the human foetus, they are to be found as large as in that of the adult.

The measured diameter of the corpuscles in *human blood* varies, according to Gulliver, from 1-2000th to 1-4000th of an inch, the average size in both sexes being 1-3200th of an inch. From an examination of numerous specimens of fresh human blood, I have found the average diameter of the globules to be the 1-3500th part of an inch, the maximum size being 1-3000th, and the minimum 1-5000th of an inch. The subjoined measurements, in fractions of an inch, are those given by Mr. Gulliver, excepting the figures in brackets, which are from my own micrometrical observations. The average diameter is, in the dog, 1-3540th (max. 1-4000th, min. 1-6000th)—in the hare, 1-3607th (1-4000th; max. 1-2000th, min. 1-8000th), in the mouse, 1-3814th—in the ass, 1-4000th—(rabbit, 1-4000th)—in the pig, 1-4230th (1-4250th)—in the ox, 1-4267th—(in the cow, 1-4000th to 1-4200th)—in the cat, 1-4400th—in the horse, 1-4600th (1-5000th)—in the sheep, 1-5300th (1-5333d to 1-6000th)—in the goat, 1-6366th. These measurements apply to *recent* blood, which has not been allowed to become dry on animal and vegetable stuffs. In this case a distinction might be easily made between the blood of a human being and a sheep or goat. With respect to the dog, hare, and rabbit it would be, even under these favorable circumstances, a matter of some difficulty. When blood is dried on clothing, and it is necessary to extract the corpuscles by means of a liquid of a different nature from the serum, it would be unsafe to rely on minute fractional differences, since we cannot be sure that the corpuscles, after having been once dried, will ever reacquire, in a foreign liquid, the exact size which they had in serum. (See "Guy's Hospital Reports," vol. 7, pt. 2, 1851.)

It is generally admitted by scientific men, that we have at present no certain method of distinguishing human from mammalian blood, when it has been once dried on an article of clothing or on a weapon. This is the practical form in which the problem usually comes before a medical jurist. He may be able to state that the shape and size of the corpuscles, as seen

by the microscope, are consistent with the blood being mammalian and probably human, but that it is impossible to say with absolute certainty that it is not the blood of an animal like the ox or pig.

Since the former edition of this work, Dr. J. G. Richardson, of Philadelphia, U. S., has made a considerable step in advance on the microscopical examination of blood. ("Amer. Jour. Med. Sci.," July, 1874.) By the use of higher powers up to 750 diameters, and by other appliances, he has been able to distinguish the blood of man from that of such animals as the ox and pig, and to give evidence thereon on certain trials for murder.

It will be understood that as the magnifying power increases, the relative difference in the size of the corpuscles is more apparent. Thus when at 300 diameters it would be scarcely possible to distinguish the blood of man from that of the pig, at 650 diameters the difference in size

Fig. 58.

Human corpuscles, 1-3500th.

Fig. 59.

Pigs' corpuscles, 1-4230th.

is well marked. The illustrations (Figs. 58 and 59), taken from a photograph by Dr. Seiler, represent, under the same power (650 diameters), the corpuscles in the blood of man and the pig. In each of the engravings only a small portion of the blood is represented, the whole of the photograph, with the two varieties of blood and the micrometric scale, being much too large for a page of this work. Dr. Seiler's process is described in the "American Medical Times," Feb. 19, 1876, page 249. The larger size of the corpuscles in human blood, Fig. 58, is at once perceptible, and it may be observed that the smallest of the human corpuscles thus highly magnified is larger than the largest of those in the pig, Fig. 59. This observation was made on fresh blood, for Dr. Seiler candidly admits that he has not been able to obtain satisfactory results with dried blood-stains, the problem which in practice most commonly presents itself for solution.

From one well experienced in the use of the higher powers of the microscope, evidence of the probable nature of the blood might be receivable, but skilled experts of this kind are rarely found among medical witnesses.

[Prof. Richardson's microscopic investigations of blood-stains are now always conducted with powers much higher than those mentioned by the author. I have examined with him blood-stains from man, the pig, the

ox, and the sheep, with powers varying from 1200 to 1800 diameters, and can testify to the obvious differences which unequivocally distinguish human blood from that of the above-mentioned animals, by the use of these high microscopic powers. Prof. Richardson's observations have afforded material aid to the cause of justice in several noted homicide trials, where the identification of suspected blood spots was a necessary factor in the evidence. By the employment of these high powers, there is no difficulty in positively distinguishing between the human blood-corpuscle and that of any animal whose corpuscle is less than the $\frac{1}{4000}$ th of an inch.—R.]

In all cases in which the microscope is employed for the examination of blood-corpuscles, a comparison of the sample should always be made with the kind of blood, whether human or animal, which it is supposed to represent.

In general it is found sufficient if the witness can say that the blood-stains on an article of dress have the characters of mammalian blood, and might be the blood of a human being. The blood of birds, fishes, and reptiles presents no difficulty, and in trials for murder at the Assizes, the statement of a prisoner is occasionally proved false by the medical evidence derived from the microscope (p. 306). At the Leeds Assizes, Nov. 1878 (*Reg. v. Ward*), prisoner was charged with murder and highway robbery. The deceased was found dead with marks of severe blows on the head. Among other circumstances which connected prisoner with this crime, was a large spot of blood upon his trousers. When asked to account for this, he said it was the blood of a fowl. The medical witness was able to state that this was not the blood of a bird but of a mammal. Poachers have their clothes often stained with blood in contests with gamekeepers. The stains have in these cases been sometimes referred to the carrying of pheasants or partridges, but the medical evidence has shown that the form of the corpuscles was inconsistent with this defence.

Blood-crystals. Hæmatin.—Another method for the microscopical detection of blood has been suggested by some German medical jurists. It consists in procuring crystals from the red coloring matter of blood. Lehmann and Kunze ascertained that all red blood is capable of crystallization, from whatever animal or organ it may have been taken. Lehmann thus describes his method of procuring these hæmatin crystals: A drop of blood which has been kept a day, is allowed to evaporate on a glass slide; a drop of distilled water is then added, and the whole is covered with a slip of thin glass. After a time, when the water has to some extent evaporated, regular red-colored crystals, of various sizes and forms, become visible under the microscope.

Another method of procuring these crystals consists in boiling the dried coagulum of blood in glacial acetic acid until dissolved, and slowly evaporating the solution. This method enables us to distinguish a coagulum of dry blood from other substances which it resembles, but it adds nothing to the certainty of detecting blood, and is not so satisfactory as the other processes described.

Spectral analysis.—Spectral analysis applied to blood has been made the subject of evidence on various trials for murder. The great advan-

tage of this optical method is that it admits of the examination of blood without in any way interfering with the subsequent application of the chemical tests already described. We simply analyze the light as it traverses a clear solution of the red coloring matter, and with a proper spectral eye-piece attached to a microscope, we notice whether the colored spectrum has undergone any change. If the red liquid owes its color to recent or oxidized blood, two dark absorption-bands will be seen breaking the continuity of the colored spectrum. These are situated respectively near the junction of the yellow with the green rays, and in the middle of the green rays. If the blood is quite recent and of a bright red color (scarlet hæmatin, cruorin, or oxyhæmoglobin) the two absorption-bands are distinct and well defined. A good light, either artificial or daylight, is required; the colored liquid should be clear and of sufficient intensity, and the spectrum apparatus properly adjusted. The blood sufficiently diluted should be placed in a thin glass reduction-tube for the purpose of examination. The spectral eye-piece allows of two of these tubes being examined at once, and it is desirable to have a specimen of blood mounted, for comparing the actual spectrum of blood with that of the suspected liquid. The results are the same with the red blood of all animals.

In the course of an hour, in warm weather, and after a day or two in cold weather, the blood in the tube undergoes a remarkable change. It loses its scarlet, and acquires a purple color (purple hæmatine). In passing to this state it has become deoxidized, and the coloring matter is now called deoxidized hæmoglobin. A small quantity of sulphide of ammonium added to red blood will produce the same effect more rapidly. In this state the two bands appear blended, and one broad black absorption band is seen nearly in the same situation. That the blood is really deoxidized is proved by the fact that, on adding to that which has spontaneously changed from red to purple a few drops of peroxide of hydrogen, the blood is reoxidized and reacquires its red color with the manifestation of the two absorption bands. The same result takes place if the purple blood is put into a wider tube and well shaken with air. The presence of two bands with this power of conversion and reconversion by deoxidizing and oxidizing agents, is characteristic of red blood. Blood which had been kept one year sealed up gave one broad black band, covering partly the orange, the whole of the yellow, and a portion of the green rays. There was also a dark band crossing the red rays of the spectrum.

When the blood by long exposure to the air has undergone chemical changes, it ceases to give any well-defined absorption-bands. In a sample of sheep's blood which had been dried and kept in a bottle about twelve years, the solution appeared to split the spectrum into three nearly equal parts: red—one black absorption-band (occupying the orange and yellow, as well as part of the green spaces), green and blue—the violet rays, as in most of the blood spectra, being absorbed.

There can be no doubt that in the hands of a competent person, and one skilled in micro-spectral observations, this optical method will enable him to discover the minutest trace of blood, provided any *red coloring matter* remains. Thus Mr. Sorby states that a spot of blood only one-tenth of an inch in diameter, or a quantity of the red coloring matter

amounting to no more than the 1000th part of a grain, was sufficient to give conclusive evidence of its presence by spectral analysis. Dr. J. G. Richardson states that by a still more delicate process he has been able to detect the 3000th part of a grain of blood on an axe handle supposed to have been used in a case of murder! Mr. Sorby detected blood in the form of deoxidized hæmatin on the rusty blade of a knife with which the murder of Mrs. Gardner was committed in 1862, after the lapse of ten years. Blood-stains which have been washed in water, and blood which has been even boiled or heated to 212° , may be thus detected. In the latter case ammonia, with the aid of a gentle heat, should be employed to dissolve the matters rendered insoluble by boiling. Spectral analysis does not enable us to make any distinction beyond that of recent and old blood, and this distinction cannot be so drawn as to enable us to fix a specific or even an approximate date. Certain accidental conditions may rapidly produce on blood the same effect as exposure to air for a long period of time. It indicates no distinction in the blood of the sexes, of the foetus and adult, or in the blood of man and animals. As a corroborative process it furnishes most valuable and trustworthy evidence, and there is no case in which blood admits of a chemical examination, in which spectral analysis does not admit of a safe application before the chemical tests are employed.

In a case of alleged murder, which was the subject of investigation in January, 1866, some faint reddish-colored stains on gray woollen cloth, visible only in a strong light, were suspected to have been caused by blood. Other stains on an overcoat worn by the accused person were also attributed to blood. Mr. Sorby examined some of the stains by this optical process, and he obtained a distinct spectrum characteristic of blood. I examined microscopically and chemically other stained portions of the gray woollen cloth, and came to the same conclusion as Mr. Sorby, namely, that the faint reddish-colored stains had been caused by blood. Our processes, although widely different, agreed in the same results, and it may be mentioned that from the fact of the blood-stains having been wetted and sponged, a more difficult case for investigation could hardly have presented itself. Our methods of examination also agreed in the result that some suspected stains or marks on the overcoat were not caused by blood. The *date* of a blood-stain cannot however be determined with any certainty by this process, unless the conditions under which it has been kept are known, and it is not possible to distinguish by it animal from human blood. (The reader will find a full description of this ingenious application of optics to legal medicine by Mr. Sorby, in the "Quarterly Journal of Science," No. 6, April, 1865, p. 205, and in the "Popular Science Review," Jan. 1866, p. 66.) A report on the comparative value of the modern methods of examining blood-stains has been published by MM. Mialhe, Mayet, Lefort, and Cornil (see "Ann. d'Hyg.," 1873, 2, p. 191), and another issued by the Russian Government in 1871 ("Anleitung zur Untersuchung Verdächtiger Flecke für Aerzte und Juristen." St. Petersburg, 1871). In the report of a case which recently occurred to Dr. Hofmann, the reader will find a full account of the application of the spectral, microscopical, and chemical processes for detecting blood. (Eulenberg's "Vierteljahrs.," 1873, 2, pp. 102–113.)

CHAPTER XXVIII.

THE CAUSE OF DEATH FROM WOUNDS.—WOUNDS DIRECTLY OR INDIRECTLY FATAL.—DEATH FROM HEMORRHAGE.—INTERNAL BLEEDING.—DEATH FROM MECHANICAL INJURY.—FROM SHOCK.—DEATH FROM NUMEROUS PERSONAL INJURIES IRRESPECTIVE OF ANY MORTAL WOUND.

It is important for a medical witness to bear in mind that in all cases of wounds criminally inflicted, the cause of death must be *certain*. No man is ever convicted upon mere medical probability. In general, there is only *one* real cause of death, although other circumstances may have assisted in bringing about a fatal result. Thus, a person cannot die of disease in the bowels and a stab in the chest at the same time, nor of apoplexy from disease and compression of the spinal marrow at the same instant. Hence it is our duty, when several apparent causes for death exist, to determine which was the *real* cause; and in stating it to the court, to be prepared to offer our reasons for this opinion. In most cases of local injury, when a person dies speedily, there will be no great trouble in settling whether disease or the injury was the cause. A difficulty may, however, exist when a person has recovered from the first effects of a wound, and has subsequently died. Besides, there may be cases in which the cause of death, in spite of the most careful deliberation, will be still obscure; or sometimes it may happen that the death of a person appears to be as much dependent on bodily disease as on an injury proved to have been received at the time he was laboring under the disease. How is an opinion to be expressed in such a case? The course which I apprehend a medical witness ought to pursue, provided, he has duly deliberated on the circumstances before he appears in court, and his mind is equally balanced between the two causes, is to state at once his doubt to the jury without circumlocution, and not allow it to be extracted from him in cross-examination. It is the hesitation to assign a satisfactory cause, or the assigning of many causes for death, that gives such advantage to a prisoner's case, even when the general evidence is entirely against him. Occasionally several causes of death are vaguely assigned by a medical witness, among which some have a tendency to exculpate and others to inculcate an accused person in a greater or less degree, and it is left to the jury to select from the number one upon which to found a verdict. In a case of this kind, an acquittal is commonly obtained.

Wounds directly or indirectly fatal.—A wound may cause death either directly or indirectly. A wound operates as a *direct cause of death* when the wounded person dies either immediately or very soon after its infliction, and there is no other cause internally or externally to account for death. In wounds which cause death *indirectly*, it is as-

sumed that the person survives for a certain period, and that the wound is followed by inflammation, suppuration, pyæmia, gangrene, tetanus, erysipelas, or some other mortal disease which is a direct, and not an unusual consequence of the injury. Under this head may also be arranged all those cases which prove fatal by reason of surgical operations rendered imperatively necessary for the treatment of an injury—presuming that these operations have been performed with ordinary skill and care. We shall for the present consider only the direct causes of death in cases of wounds. They are three in number: 1. *Hemorrhage*, or loss of blood. 2. *Great mechanical injury* done to an organ important to life. 3. *Shock*, or *concussion*, affecting the brain or spinal marrow, whereby the functions of one or more vital organs are arrested, sometimes with but slight injury to the part struck or wounded. From either of these causes, a wounded person may die immediately, or within a few minutes.

1. *Death from hemorrhage*.—Loss of blood operates by producing fatal syncope (p. 59). A quantity of blood escaping from a vessel, although insufficient to cause death by affecting the heart and circulation, may readily destroy life by disturbing the functions of the organ or part into which it is effused. Thus, a small quantity effused in or upon the substance of the brain, or at its base, may prove fatal by inducing fatal compression; and again, if, in a case of wounded throat, blood should flow into the windpipe, it may cause death by asphyxia—i. e., by stopping the respiratory process (p. 59). In these cases, it is obvious that the blood acts mechanically; and in respect to the last condition, a medical man, unless circumspection is used, may involve himself in a charge of malapraxis. If he allows the wound to remain open, the wounded person may die through hemorrhage—if he closes it too soon, he may die through suffocation; and, in either case, the counsel for a prisoner will not fail to take advantage of a plausible objection of this kind. In wounds of the chest, involving the heart and lungs, death is frequently due not so much to the actual quantity of blood effused, as to the pressure which it produces upon these organs. A few ounces effused in the cavity of the membrane including the heart (pericardium), will entirely arrest the action of this organ.

The absolute *quantity of blood* required to be lost in order to prove fatal, will, of course, vary according to numerous circumstances. The young, the aged, and those who are laboring under infirmity or disease, will perish sooner from loss of blood than others who are healthy and vigorous. Women, *cæteris paribus*, are more speedily destroyed by bleeding than men. Infants are liable to die from this cause, as a result of slight wounds. An infant has been known to bleed to death from the bite of a single leech, or from the simple operation of lancing the gums. Even the healthy and vigorous, when their vital powers have been depressed by maltreatment or by brutal violence, will sink under the loss of a comparatively small quantity of blood. (“Watson on Homicide,” p. 90.) A medical jurist must not forget that some persons have a predisposition to excessive bleeding from slight injuries; and this condition is often hereditary. The slightest wound or puncture—the bite of a leech or the extraction of a tooth—will be attended with a loss of blood which

cannot be arrested, and which will slowly lead to death by exhaustion. Cases have been frequently recorded in our medical journals of fatal hemorrhage following the extraction of teeth, when there had been previously nothing to indicate the probable occurrence of death from so trivial a cause. Such cases are without difficulty detected; since a surgeon may always infer, from the part injured and the extent of the injury, whether the bleeding is likely to be copious or not. When a person bleeds to death from what would, under common circumstances, be a simple wound, the admission of this fact may in certain cases lessen the responsibility of an accused party.

A *sudden loss* of blood has a much more serious consequence than the same quantity lost slowly. A person may fall into a fatal syncope from a quantity of blood lost in a few seconds, which he would have been able to bear without sinking had it escaped slowly. This is the reason why the wound of an artery proves so much more rapidly fatal than that of a vein. Death speedily follows the wound of a large artery like the carotid; but it takes place with equal certainty, although more slowly, from wounds of smaller arteries. In a case in which one of the intercostal arteries was wounded by a small shot, hemorrhage caused death in thirty-eight hours. The loss of blood which follows the division of the smaller branches of the external carotid artery is often sufficient to destroy life, unless timely assistance be rendered. If a wound is in a vascular part, although no vessel of any importance be divided, the person may still die from bleeding. It is difficult to say what *quantity* of blood should be lost, in order that a wound may prove fatal. The whole quantity contained in the body of an adult is calculated at about one-fifth of its weight—i. e., about thirty pounds; of this, one-fourth is considered to be arterial, and the remaining three-fourths are venous blood. Some physiologists have estimated the proportion to prove fatal as one-eighth of the weight of the body. ("Med. Times and Gaz.," Aug. 28, 1858, p. 232.) According to Mr. Watson the loss of from five to eight pounds is sufficient to prove fatal to adults. But while this may be near the truth, many persons will die from a much smaller quantity; the *rapidity* with which the effusion takes place having a considerable influence as well as the age, sex, and bodily condition of the wounded person. It has been found, by experiment, that a dog cannot bear the loss of more blood than is equivalent to one-twelfth part of the weight of its body.

Internal hemorrhage.—Hemorrhage may prove fatal, although the blood does not visibly escape from the body. In incised wounds, the flow externally is commonly abundant; but in contused, punctured, and gunshot wounds, the effusion may take place internally and rapidly cause death. In severe contusions, or contused wounds, involving highly vascular parts, the effusion may go on to an extent to prove fatal, either in the cavities of the body or throughout the cellular membrane and parts adjacent; many pounds of blood may thus be slowly or rapidly effused. The most fatal internal hemorrhages are those which follow ruptures of the organs from violence or disease. Ruptures of the heart, lungs, liver, and kidneys have thus caused death. In November, 1864, a man who had been run over was brought to Guy's Hospital. He complained of pain in the back, but there were no symptoms of severe injury, and no

marks of violence were seen on the skin of the back. He left the hospital and walked with some assistance to his home. A few hours afterwards he was found dead in bed. On inspection there was a large quantity of blood effused in the abdomen. This had proceeded from *one* kidney, which had been ruptured transversely through its whole substance. In these cases the bleeding is not necessarily immediate; but slight muscular exertion may increase it, and accelerate death. In death from severe flagellation, blood may be effused in large quantity beneath the skin and among the muscles; this effusion will operate as fatally as if it had flowed from an open wound.

The means of ascertaining whether a person has died from bleeding by an open wound are these: Unless the wound is situated in a vascular part we shall find the vessel or vessels from which the blood has issued divided—the neighboring vessels empty, and the body more or less pallid; although this last condition is of course liable to be met with in certain cases of disease, as also under copious venesection—points easily determined by an examination. The blood will commonly be found more or less clotted or coagulated on those surfaces on which it has fallen. If, with these signs, there is an absence of disease likely to prove rapidly fatal, and no other probable cause of death is apparent, it may be fairly referred to loss of blood. This opinion may, however, be materially modified in reference to open wounds, by the fact of the body not being seen on the spot where the injury was actually inflicted—by the wound having been sponged—the blood removed by washing, and all traces of bleeding destroyed. Under these circumstances, the case must in a great measure be made out by presumptive proof; and here a medical witness may have the duty thrown upon him of examining articles of dress, furniture, or weapons, for marks or stains of blood. It must not be supposed that all the blood met with round a wounded dead body, or in a cavity of the body, was actually effused during life. As soon as the heart's action ceases, the arteries pour out no more; but the blood, so long as it remains liquid, *i. e.*, from four to eight or ten hours after death, and the warmth of the body is retained, continues to drain from the divided veins and smaller vessels. The quantity thus lost, however, is not considerable, unless the veins implicated are large, or the part is highly vascular, *i. e.*, full of veins or small vessels.

2. *Death from great mechanical injury done to a vital organ.*—We have instances of this becoming a direct cause of death in the crushing of the heart, lungs, or brain by any heavy body passing over or falling on the cavities, as in railway accidents. The severe mechanical injury is sometimes accompanied by a considerable effusion of blood, so that the person really dies from hemorrhage; but in other instances the quantity of blood is inconsiderable, and the fatal effects may be referred to shock to the nervous system. Sometimes a slight amount of violence may prove suddenly fatal. These are, however, to be regarded as exceptional instances.

3. *Death from shock.*—This is sometimes a direct cause of death under the infliction of external violence; and in this case life is destroyed without the injury being to all appearance sufficient to account for so speedily fatal a result. On several occasions persons have died in railway colli-

sions from no physical injury, but from pure shock to the system. In a collision which took place in November, 1873, at the Durham Station, a *Mrs. Coble* was among the dead. On a post-mortem examination there was no appearance of external or internal violence. Mr. Savory has suggested that death from shock is nothing more than death from temporary exhaustion of nerve-force, the result of a violent, sudden, and excessive expenditure of it. ("Lectures on Life and Death," p. 171.) Whatever theory may be adopted to explain it, there is no medical doubt that a person may die from what is termed shock, without any marks of severe injury being discovered on his body after death. We have examples of this mode of death in accidents from lightning, or from severe burns or scalds, in which the local injury is often far from sufficient to explain the rapidly fatal consequences. As instances of this form of death from violence, may be also cited those cases in which a person has been suddenly killed by a blow upon the upper part of the abdomen or on the pit of the stomach, which is supposed to operate by producing a fatal impression on the nerves and nerve ganglia of the cardiac plexus. Whether this be or be not the true explanation, it is admitted by experienced surgeons that a person may die from so simple a cause without any mark of a bruise externally, or physical injury internally to account for death. On the skin there may be some abrasion or slight discoloration; but as it has been elsewhere stated these are neither constant nor necessary accompaniments of a blow. Concussion of the brain, unattended by visible mechanical injury, furnishes another example of this kind of death. A man receives a severe blow on the head; he falls dead on the spot, or becomes senseless and dies in a few hours. On an inspection, there may be merely the mark of a bruise on the scalp; in the brain there may be no rupture of vessels or laceration of substance, and all the other organs of the body may be found healthy. In certain railway accidents persons have died under somewhat similar circumstances. There has been no physical indication of a mortal injury, and no cause apparent to account for death. This can be referred only to the shock or violent impression which the nervous system has sustained from the blow or violence—an impression which the vital powers were wholly unable to counteract or resist. A medical witness must give his evidence with caution in such case; since it is the custom to rely in the defence upon the absence of any visible *mortal* wound or physical injury to account for death, as a proof that no injury was done—a principle which, if once unrestrictedly admitted, would leave a larger number of deaths, undoubtedly occurring from violence, wholly unexplained.

There is another form of shock, which is of some importance in medical jurisprudence. A person may have received *many injuries* as by blows or stripes, not one of which, taken alone, could, in medical language, be termed mortal; and yet he may die directly from the effects of the violence, either on the spot, or very soon afterwards. In the absence of any large effusion of blood beneath the skin, death is commonly referred to exhaustion, but this is only another mode of expression; the exhaustion is itself dependent on a fatal influence or impression produced on the nervous system. A prizefighter, after having sustained during many rounds, numerous blows on the body, may either at or after the

fight, sink or die exhausted. His body may present marks or bruises or even lacerated wounds, but there may be no internal changes to count for death. In common language, there is not a single injury which can be termed *mortal*; and yet, supposing him to have had good health previously to the fight, and all marks of disease indicative of sudden death to be absent, it is impossible not to refer his death to the direct effect of violence. It is a well ascertained medical fact, that a number of injuries, each comparatively slight, are as capable of operating fatally, as any single wound whereby some bloodvessel or organ important to life is directly affected. Age, sex, constitution, and a previous state of health or disease, may accelerate or retard the fatal consequences. In *Reg. v. Slane* and others, Durham Winter Assizes, 1872, it was proved that deceased had sustained severe injuries to the abdomen by kicks and other violence, but there were no marks of bruises. On a post-mortem examination, all the organs were healthy. Nevertheless, death took place twenty minutes after the maltreatment. Death was attributed to shock and the prisoners were convicted of murder. A case of manslaughter involving this question was tried in the Midland Circuit, Leicester, Nov. 1877. Three men were charged with murder of the deceased. It was proved that he had been maltreated by kicking and by blows inflicted with heavy stones. He died in four days, obviously from the effects of the violence. The medical evidence showed that the nasal bones were much fractured as by a blow from a heavy stone, and that there were fractures of one clavicle and several ribs. The witness assigned the cause of death to shock to the system, from the number of injuries received and the inflammation set up by them. The whole of the injuries in his opinion combined to cause death. (*Reg. v. McGowan* and others.) The prisoners were convicted.

From these considerations, it is obviously unreasonable to expect that in every case of death from violence or maltreatment there must be some specific and visible *mortal injury* to account for this event. When the circumstances accompanying death are unknown, a medical opinion should certainly be expressed with caution; but if we are informed that the deceased was in ordinary health and vigor previous to the infliction of the violence, and there is no morbid cause to account for his *sudden* illness and death, there is no reason why we should hesitate in referring death to the effects of a number of injuries. Among non-professional persons an unfounded prejudice exists that no person can die from violence unless there is some distinctly *mortal* wound actually inflicted on the body. By this we are to understand a *visible* mechanical injury to some organ or bloodvessel important to life; but this is obviously an erroneous notion since death may take place from the disturbance of the functions of an organ important to life, without this being necessarily accompanied by a perceptible alteration of structure. The prevalence of this popular error often leads to a severe cross-examination of medical witnesses. Among the questions put, we sometimes find the following: Would you have said, from the wounds or bruises *alone*, that they were likely to have occasioned death? Now, in answer to this, it may be observed, that we cannot always judge of the probability of death ensuing, from the appearance of external violence alone. Because the appearances were slight.

it would be wrong to infer that they were *not* sufficient to cause death by shock. Then it may be inquired, Were the wounds or bruises mortal? In the vulgar sense of the word, *i. e.*, by producing great loss of blood, or a destruction of parts, they might not be so; but in a medical view, they may have acted mortally by producing a shock to the nervous system. Again it may be inquired, Which of the several wounds or bruises found on the body of the deceased, was mortal? The answer to this question may be—Not one individually, but *all* contributed to occasion death by syncope or exhaustion. It must be remembered that in cases in which a person has sustained a number of injuries, the loss of a much smaller quantity of blood than in other instances will suffice to destroy life.

When there are several wounds, it is difficult to decide on their relative degree of mortality, and on the share which each may have had in causing death. By a wound being of itself *mortal*, we are to understand that it is capable of causing death directly or indirectly, in spite of the best medical assistance. It is presumed that the body is healthy, and that no cause has intervened to bring about or even accelerate a fatal result. The circumstance of a person laboring under disease when wounded in a vital part, will not, of course, throw any doubt upon the fact of such a wound being necessarily mortal, and of its having caused death. If there should be more wounds than one, it is easy to say from the nature of the parts involved, which was likely to have led to a fatal result. In order to determine, on medical grounds, whether a wound was or was not mortal, we may propose to ourselves this question: Would the deceased have been likely to die at the same time, and under the same circumstances, had he not received the wound? There can obviously be no general rule for determining the mortal nature of wounds. Each case must be judged by the circumstances which attend it.

In some Continental states, the law requires that a medical witness should draw a distinction between a wound which is *absolutely* and one which is *conditionally* mortal. An absolutely mortal wound is defined to be that in which the best medical assistance being at hand, being sent for, or actually rendered, the fatal event could not be averted. Wounds of the heart, aorta, and internal carotid arteries, are of this nature. A conditionally mortal wound is one in which, had medical assistance been at hand, been sent for, or timely rendered, the patient would, in all probability, have recovered. Wounds of the brachial, radial, and ulnar arteries may be taken as instances. The responsibility of an assailant is made to vary according to the class of injuries to which the wound may be referred by the medical witnesses; and, as it is easy to suppose, there is seldom any agreement on this subject. Our criminal law is entirely free from such subtleties. The *effect* of the wound, and the *intent* with which it was inflicted, are looked to: its anatomical relations, which must depend on pure accident, are never interpreted in a prisoner's favor. Some extenuation may, perhaps, be occasionally admitted when a wound proves mortal through an indirect cause, as inflammation or fever, and medical advice was obtainable, but not obtained until every hope of recovery had disappeared. It appears, however, from the case of the *Queen v. Thomas and others* (Gloucester Aut. Ass. 1841), that the mere

neglect to call in medical assistance is not allowed in law to be a mitigatory circumstance in the event of death ensuing. The deceased died from the effects of a severe injury to the head, inflicted by the prisoners, but had had no medical assistance. The judge said it was possible that "if he had had medical advice, he might not have died; but whoever did a wrongful act must take the whole consequences of it. It never could make any difference whether the party injured had or had not the means or the mind to apply for medical advice." The prisoners were convicted. According to Lord Hale, if a man be wounded, and the wound, although not in itself mortal, turn to a gangrene or fever for want of proper applications, or from neglect, and the man die of gangrene or fever, this is homicide in the aggressor; for though the fever or gangrene be the immediate cause of death, yet the wound being the cause of the gangrene or fever is held the cause of death. These nice questions relative to the shades of responsibility for personal injuries, occasionally arise in cases in which persons have been wounded at sea on board of a ship in which there was no surgeon.

CHAPTER XXIX.

DEATH OF WOUNDED PERSONS FROM NATURAL CAUSES.—DISTINCTION BETWEEN REAL AND APPARENT CAUSE.—DEATH FROM WOUNDS OR LATENT DISEASE.—ACCELERATING CAUSE.—DEATH FROM WOUNDS AFTER LONG PERIODS.—AVOIDABLE CAUSES OF DEATH.—NEGLECT.—IMPRUDENCE.—UNSKILFUL TREATMENT.—UNHEALTHY STATE OF BODY.

Death of wounded persons from natural causes.—It is by no means unusual for individuals who have received a wound, or sustained some personal injury, to die from latent natural causes; and as, in the minds of non-professional persons, death may appear to be a direct result of the injury, the case can only be cleared up by the assistance of a medical practitioner. Such a coincidence has been witnessed in many instances of attempted suicide. A man has inflicted a severe wound on himself while laboring under disease; or some morbid change tending to destroy life has occurred subsequently to the infliction of a wound, and death has followed. Without a careful examination of the body, it is impossible to refer death to the real cause. The importance of an accurate discrimination in a case in which wounds or personal injuries have been caused by another, must be obvious on the least reflection. A hasty opinion may involve the accused in a charge of manslaughter; and although a barrister might be able to show on the trial that death was probably attributable not to the wound, but to coexisting disease, yet it must be remembered that the evidence of a surgeon before a coroner or magistrate, in remote parts of this country, may be the means of causing the person charged to be imprisoned for some months previously to the trial. This is in itself a punishment, independently of the loss of character to which he must be in the mean time exposed.

Death from wounds or latent disease.—A natural cause of death may be lurking within the body at the time that a wound is criminally inflicted, and a close attention to the symptoms preceding, and the appearances after death, can alone enable a surgeon to distinguish the real cause. A man may be severely wounded, and yet death may take place from rupture of the heart, the bursting of an aneurism, from apoplexy, phthisis, or other morbid causes which it is here unnecessary to specify. (“*Cormack’s Ed. Jour.*,” May, 1846, p. 343.) If death can be clearly traced to any of these diseases by an experienced surgeon, the assailant cannot be charged with manslaughter; for the medical witness may give his opinion that death would have taken place about the same time and under the same circumstances, whether the wound had been inflicted or not.

On these occasions one of the following questions may arise: Was the death of the person accelerated by the wound, or was the disease under which he was laboring so aggravated by the wound as to produce a more speedily fatal termination? The answer to either of these questions must depend on the circumstances of each case, and the witness’s ability to draw a proper conclusion from these circumstances. The maliciously accelerating of the death of another already laboring under disease, is criminal; for in a legal sense what accelerates, causes. In *Reg. v. Timms* (Oxford Lent Ass., 1870), it was proved that prisoner had struck deceased some blows on the head with a hatchet. In twelve days, under treatment, he had partly recovered from the effects, but in six weeks afterwards he was seized with inflammation of the brain, with convulsions, and died. On inspection, disease of the kidneys was found, of which there had been no symptoms. Death was referred to this disease and to inflammation of the brain, as the result of the blows. The learned judge directed the jury that if they believed the blows conduced in part to the death of the deceased, it was manslaughter, notwithstanding that other causes had combined with the blows to account for death. The prisoner was convicted. But there may be no connection between the violence and the disease causing death. In this case a charge of murder falls to the ground. In *Reg. v. Thompson* (Liverpool Summer Ass., 1876), involving a charge of murder, it was proved that the prisoner had stabbed his wife in the cheek, producing a severe but not a mortal wound. This was on the first April. The deceased was taken to an infirmary, and was there delivered of a child on the 3d. She was attacked with puerperal fever, and died on the 12th. It was properly stated by the medical witness that there was no necessary connection between the wound and the fever. Prisoner was acquitted on the charge of murder, and his life was saved. He was found guilty of wounding with intent to murder. In another case, *Reg. v. Hodgson* (Leeds Summer Ass., 1876), prisoner was charged with the manslaughter of his wife by striking her with a belt. A short time after, she fell back and died suddenly. The proximate cause of death was proved to be heart disease—the violence not being sufficient to account for it. Prisoner was acquitted.

In December, 1873, an inquest was held at Haslar hospital on the body of one *Rollings*. On the 26th, the deceased was struck by a seaman, and fell with his right arm under him, breaking the two bones of the

fore-arm just above the wrist. He died rather suddenly soon after the violence, and as this did not seem adequate to account for death, a careful inspection was made, and it was then found that death had resulted from disease of the heart.

Lord Hale, in remarking upon the necessity of proving that the act of a prisoner caused the death of a person, says: "It is necessary that death should have been occasioned by some corporeal injury done to the party by force, or by poison, or by some mechanical means which occasioned death; for although a person may, *in foro conscientiæ*, be guilty of murder by working on the passions or fears of another, and certainly occasion death by such means as if he had used a sword or pistol for the purpose, he is not the object of temporal punishment. (I. 247.) Several acquittals have taken place of late years, in cases in which the deaths of persons have been occasioned by terror, or dread or impending danger, produced by acts of violence on the part of the prisoners, not, however, giving rise to bodily injury in the deceased. Under the 14 and 15 Vict. c. 100, the necessity for tracing death to some corporeal injury appears to be practically abolished. According to the fourth section, in any future indictment for murder or manslaughter it shall not be necessary to set forth the *manner* or the *means* by which the death of the deceased was caused. This question arose in *Reg. v. Heany* (Gloucester Lent. Ass., 1875). The prisoner was charged with the manslaughter of his wife. She was suffering from cancerous disease. In the course of an altercation the prisoner held up a knife in a threatening manner, but without touching her. This produced a shock, and she died two days after, from fright. Prisoner was acquitted, as there was no distinct proof of the acceleration of death by his act. He was convicted of an assault.

Which of two wounds caused death.—A man may receive two wounds on provocation, at different times, and from different persons, and die after receiving the second: in such a case, the course of justice may require that a medical witness should state which wound was the cause of death. Let us take the following illustration: A man receives during a quarrel a gunshot wound in the shoulder. He is going on well, with a prospect of recovery, when in another quarrel he receives a severe penetrating wound in the chest or abdomen from another person, and after lingering under the effects of these wounds for a longer or shorter period he dies. If the gunshot wound was clearly shown to have been the cause of death, the second prisoner could not be convicted of manslaughter; or if the stab was evidently the cause of death, the first prisoner would be acquitted on a similar charge. It might be possible for a surgeon to decide the question summarily, when, for instance, death speedily followed the second wound; and on inspection of the body the heart or a large vessel is discovered to have been penetrated; or, on the other hand, extensive sloughing, sufficient to account for death, might take place from the gunshot wound, and on inspection the stab might be found to be of a slight nature, not involving any vital parts. In either of these cases, all would depend upon the science, skill and judgment of the medical practitioner; his evidence would be so important that no correct decision could be arrived at without it; he would be, in fact

called upon substantially to distinguish the guilty from the innocent. In *Reg. v. Foreman* (C. C. C., Feb. 1873), this question arose. The prisoner, it was proved, had struck the deceased some severe blows on the head. A fortnight afterwards, the deceased, who had partially recovered, had a fight with another man, during which he received severe blows on his head. In another fortnight he had paralysis on the left side, and died in a hospital a few days afterwards. On inspection, a large abscess in the brain was found, which was the cause of the symptoms and death. The question was, whether this abscess had arisen from the blows given by the prisoner, or from the violence sustained a fortnight afterwards. On this point there was no satisfactory medical evidence, and as deceased had had no serious symptoms for a fortnight after the assault by the prisoner, in fact not until after the second fight, the jury acquitted him.

On some occasions death may appear to be equally a consequence of either or both of the wounds ; in which case probably both parties would be liable to a charge of manslaughter. (See "*Ann. d'Hyg.*," 1835, vol. 2, p. 432.) The second wound, which is here supposed to have been the act of another, may be inflicted by a wounded person on himself, in an attempt at suicide, or it may have an accidental origin. The witness would then have to determine whether the wounded person died from the wound inflicted by himself, or from that which he had previously received.

It may happen that the wounded person has taken *poison*, and has actually died from its effects, and not from the injuries or maltreatment. Again, a wounded person may have been the subject of subsequent ill-treatment, and the question will arise—to which of the two causes his death was really due. It is to be observed of these cases, that the supervening disease, the poison, or the subsequent ill-treatment, should be of such a nature as to account for *sudden or rapid death* ; since it would be no answer to a charge of death from violence, to say that there were marks of chronic disease in the body, unless it was of such a nature as to account for the sudden destruction of life under the symptoms which actually preceded death. In the medical jurisprudence of wounds, there is probably no question which so frequently presents itself as this : it is admitted that the violence was inflicted, but is asserted that death was due to some other cause, and the onus of proof lies on the medical evidence. Among numerous cases which have occurred in England during a period of twenty years, I find that the latent causes of death in wounded persons have been chiefly inflammation of the thoracic or abdominal viscera, apoplexy, diseases of the heart and large bloodvessels, phthisis, ruptures of the stomach and bowels from disease, internal strangulation, and the rupture of deep-seated abscesses. In some of these cases the person was in a good state of health up to the time of the violence, and in others there was merely a slight indisposition. The history is nearly the same in all ; it was only by careful conduct on the part of the medical witnesses that the true cause of death was ascertained. It is obvious that questions of malapraxis and life-insurance, giving rise to civil actions, may have a close relation to this subject.

Death following slight personal injuries.—An imputation has occasionally been thrown on the master of a school, when a boy has died soon after he has been punished in an ordinary way, and when there has been no suggestion that an undue amount of violence was used. In such cases there has been commonly some unhealthy state of the body to explain the fatal result. When the disease which gives rise to doubt is seated in a part which is remote from that which sustained the violence, all that is required is, that the examination of the body should be conducted with ordinary care. If the disease should happen to be in the part injured (the head or chest), the case is more perplexing. The difficulty can then be removed only by attentively considering the usual consequences of such injuries. The violence may have been too slight to account for the diseased appearance; and the disease itself, although situated in the part injured, may be regarded as an unusual consequence of such an injury. On the other hand, the presence of chronic disease will form no exculpation of acts of violence of this nature. In *Reg. v. Hopley* (Lewes Aut. Ass., 1860), there was chronic disease of long standing in the brain of the deceased boy, but it was proved that he was quite well and suffered from no unusual symptoms up to the time that a violent flogging was inflicted, and that this was followed by death in less than three hours from the commencement of the violence. It was not here a question even of acceleration, for the deceased might have lived for years in spite of the existence of this chronic disease. In some cases *slight blows* have been followed by fatal consequences, even when no disease existed to account for the result. Mr. Annan describes a case in which a healthy girl of four received a slight blow on the shin, about three inches below the knee, from the shaft of a wheelbarrow. There was pain but no external mark of violence. The injury was considered to be so slight as to require no special treatment. On the following day there was increased pain. Severe constitutional symptoms set in, and the child died on the fourth day. ("Med. Times," Aug. 1854.)

Death from wounds after long periods.—Certain kinds of injuries are not immediately followed by serious consequences, but a wounded person may die after a longer or shorter period of time, and his death may be as much a consequence of the injury as if it had taken place on the spot. The aggressor, however, is just as responsible as if the deceased had been directly killed by his violence, provided the fatal result can be traced to the usual and probable consequences of the injury. Wounds of the head are especially liable to cause death insidiously—the wounded person may in the first instance recover—he may appear to be going on well, when, without any obvious cause, he will suddenly expire. It is scarcely necessary to observe, that in general an examination of the body will suffice to determine whether death is to be ascribed to the wound or not. In severe injuries affecting the spinal marrow, death is not an immediate consequence, unless that part of the organ which is above the origin of the phrenic nerves (supplying the diaphragm) is wounded. Injuries affecting the lower portion of the spinal column do not commonly prove fatal until after some days or weeks; but the symptoms manifested by the patient during life, as well as the appearances observed in the body after death, will sufficiently connect the injury

with that event. Death may follow a wound, and be a consequence of that wound, at almost any period after its infliction. It is necessary, however, in order to maintain a charge of homicide, that death should be strictly and clearly traceable to the injury, and not be dependent on any other cause. A doubt on this point must, of course, lead to an acquittal of the accused.

Many cases might be quoted in illustration of the length of time which may elapse before death takes place from certain kinds of injuries, the injured person having ultimately fallen a victim to their indirect consequences. A case is related by Sir A. Cooper, of a gentleman who died from the effects of an injury to the head received about *two years* previously. The connection of death with the wound was clearly made out by the continuance of the symptoms of cerebral disturbance during the long period which he survived. Another case is mentioned by Hoffbauer, in which a person died from the effects of concussion of the brain as the result of an injury received eleven years before. ("Ueber die Kopfverletzungen," 1842, p. 57.)

There is a singular rule in our law relative to the period at which a person dies from a wound—namely, that the assailant shall not be adjudged guilty of murder, unless death takes place *within a year and a day* after the infliction of the wound. (Archbold, p. 345.) It is a general rule that to make the killing murder, the death must follow within a year and a day after the stroke or other cause of it. In practice, the existence of this rule is of little importance, but in principle it is erroneous. Most wounds leading to death generally destroy life within two or three months after their infliction: sometimes the person does not die for five or six months, and in more rare instances, death does not ensue until after the lapse of twelve months, or even several years. (See cases *supra*.) These protracted cases occur especially in respect to injuries of the head and chest. In *Reg. v. Creuse* (Shrewsbury Summer Ass., 1873), prisoner was charged with the murder of a policeman (Lloyd), by knocking him down and kicking him on the chest and abdomen, on June 20, 1872. Lloyd appeared to be much exhausted, but at first no serious injury was apprehended. The assailant was brought before the magistrates, and imprisoned for the assault. The day after the assault, Lloyd began to spit blood, but he continued to do duty until July 9 following. He then got gradually worse, and died on June 8, 1873, from the effects of the violence inflicted on him nearly a year previously. Had the deceased lived thirteen days longer, the prisoner could not have been indicted for murder, as a year and a day would have elapsed after the stroke causing death. As it was, the jury found the prisoner guilty of manslaughter.

Secondary causes of death.—A person who recovers from the immediate effects of a wound may die from fever, inflammation or its consequences, pyæmia, erysipelas, delirium tremens, tetanus or gangrene; or an operation required during the treatment of a wound may prove fatal. These are what may be called secondary causes of death, or secondary fatal consequences of a wound. The power of deciding on the responsibility of an accused person for an event which depends only in an indirect manner on an injury originally inflicted by him, rests of course with the

authorities of the law. But it is impossible that they can decide so difficult and nice a question in the absence of satisfactory medical evidence; and on the other hand, it is right that a medical witness should understand the importance of the duty here required of him. *Fever* or *erysipelas* may follow many kinds of serious wounds, and in some few instances be distinctly traceable to them; but in others, the constitution of a person may be so broken up by dissipated habits as to render a wound fatal which in a healthy subject might have run through its course mildly, and have healed. When the fever or erysipelas can be traced to a wound, and there is no other apparent cause of aggravation to which either of these disordered states of the body can be attributed, they can scarcely be regarded by a medical practitioner as unexpected and unusual consequences, especially when the injury is extensive, and seated in certain parts of the body, as in the scalp. If death take place under these circumstances, the prisoner will be held as much responsible for the result as if the wound had proved directly mortal. This principle has been frequently admitted by our law, and, indeed, were it otherwise, many reckless offenders would escape, and many lives would be sacrificed with impunity. It is, however, difficult to lay down general rules upon a subject which is liable to vary in its relations in every case; but when a wound is not serious, and the secondary cause of death is evidently due to constitutional peculiarities from acquired habits of dissipation, the ends of justice are probably fully answered by an acquittal; in fact, such cases do not often pass beyond a coroner's inquest.

The secondary causes of death may be arranged under the following heads:—

1. *The cause is unavoidable.*—Of this kind are tetanus, following laceration of tendinous and nervous structures—erysipelas following lacerated wounds of the scalp—peritoneal inflammation following blows on the abdomen with or without rupture of the bladder or intestines, and effusion of their contents—strangulation of the intestines (phrenic hernia), following rupture of the diaphragm, and others of a like nature. Here, supposing proper medical treatment and regimen to have been pursued, the secondary cause of death was unavoidable, and the fatal result certain.

2. *The cause avoidable by good medical treatment.*—There are, it is obvious, many kinds of wounds which, if properly treated in the first instance, may be healed and the patient recover, but when improperly treated they prove fatal. In the latter case it will be a question for a witness to determine how far the treatment aggravated the effects of the violence, and from his answer to this, the jury may have to decide on the degree of criminality which attaches to the accused. Let us suppose, for instance, that an ignorant person has removed a clot of blood, which sealed up the extremity of a bloodvessel, in consequence of which fatal bleeding has ensued, or that he has caused death by unnecessarily interfering with a penetrating wound of the chest or abdomen, it would scarcely be just to hold the aggressor responsible, since, but for the gross ignorance and unskillfulness of his attendant, the wounded person might have recovered from the effects of the wound. When death is really traceable to the negligence or unskillfulness of a surgeon who is called

to attend on a wounded person, this circumstance ought to be, and commonly is, admitted in mitigation, supposing that the wound was not originally of a mortal nature. Lord Hale observes: "It is sufficient to constitute murder, that the party dies of the wound given by the prisoner, although the wound was not originally mortal, but became so in consequence of negligence or unskilful treatment; but it is otherwise where death arises, not from the wound, but from unskilful applications or operations used for the purpose of curing it." (1, 428.) The medical jurist will perceive that a very nice distinction is here drawn by this great judge, between death as it results from a wound rendered mortal by improper treatment, and death as it results from improper treatment, irrespective of the wound. In the majority of cases such a distinction could scarcely be established, except upon speculative grounds, and in no case, probably, would there be any accordance in the opinions of medical witnesses. In slight and unimportant wounds, it might not be difficult to distinguish the effects resulting from bad treatment from those connected with the wound, but there can be few cases of severe injury to the person, wherein a distinction of this nature could be safely made; and the probability is that no conviction for murder would now take place, if the medical evidence showed that the injury was not originally mortal, but only became so by unskilful or improper treatment. In such a case, it would be impossible to ascribe death to the wound, or to its usual or probable consequences; and without this it is not easy to perceive on what principle an aggressor could be made responsible for the result. [In *Commonwealth v. Hackett*, 2 Allen (Mass.) 136, it was held that one who has wilfully inflicted upon another a dangerous wound, with a deadly weapon, from which death ensues, is guilty of murder or manslaughter, as the evidence may prove, although through want of care or skill, the improper treatment of the wound by surgeons may have contributed to the death. See, also, *Commonwealth v. Green*, 1 Ash. 289.—P.]

3. *Comparative skill in treatment.*—If death has been caused by a wound, the responsibility of an aggressor is not altered by the allegation that under more favorable circumstances, and with *more skilful treatment*, a fatal result might have been averted. At the same time it is obvious that a serious responsibility is thrown on practitioners who undertake the management of cases of criminal wounding. Any deviation from ordinary practice should, therefore, be made with the greatest caution, since novelties in practice will, in the event of a fatal result, form one of the best grounds of defence in the hands of a prisoner's counsel. On these occasions every point connected with the surgical treatment will be the subject of rigorous inquiry and adverse professional criticism. In the case of a severe lacerated wound in the hand or foot followed by fatal tetanus, it may be said that the wounded person would not have died had amputation been at once performed. In this instance, however, a practitioner may justify himself by showing either that the injury was too slight to require amputation, or that the health or other circumstances connected with the deceased, would not allow of its being performed with any reasonable hope of success. On the other hand, if the practitioner performed amputation, and the patient died, then it would be

urged that the operation was premature, or wholly unjustifiable, and that it had caused death. Here the surgeon is bound to show that the operation was necessary according to the ordinary rules of practice. The treatment of severe incised wounds of the throat, when the windpipe is involved, sometimes places a surgeon in an embarrassing position. If the wound is left open, death may take place from bleeding; if it be prematurely closed, blood may be effused into the windpipe, and cause death by suffocation.

4. *The cause avoidable but for imprudence or neglect on the part of the wounded person.*—A man who has been severely wounded in a quarrel may obstinately refuse medical assistance, or he may insist upon taking exercise, or using an improper diet, contrary to the advice of his medical attendant; or by other imprudent practices, he may thwart the best conceived plans for his recovery. Let us take a common case as an illustration. A man receives a blow on the head in a pugilistic combat, from the first effects of which he recovers, but after having received surgical assistance, he indulges in excessive drinking, and dies. The aggressor is tried on a charge of manslaughter, and found guilty. Death under these circumstances is commonly attributed by the medical witness to effusion of blood on the brain; but it cannot be denied that the excitement produced by intoxicating liquors will sometimes satisfactorily account for the fatal symptoms. In the case which we are here supposing, such an admission might be made, and the prisoner receive the benefit of it; for the imprudence or negligence of a wounded person ought not, morally speaking, to be considered as adding weight to the offence of the aggressor. If the symptoms were from the first unfavorable, or the wound likely to prove mortal, circumstances of this kind could not be received in mitigation. Our judges have shown themselves at all times unwilling to admit them. The legal responsibility of the assailant is the same, whether the deceased died on the spot, or some days, weeks, or months afterwards, unless it can be distinctly proved that his death was immediately connected with the imprudence or excess of which he was guilty, and wholly independent of the wound. But, although a prisoner should be found guilty of manslaughter under these circumstances, the punishment is so adjusted by our law as to leave a considerable discretionary power in the hands of a judge. This is, indeed, tantamount to a direct legal provision, comprehending each different shade of guilt; a man is held responsible for a wound rendered accidentally mortal by events over which he could have had no control, but which in themselves ought to be regarded as in some degree exculpatory. The punishment attached to his offence may be severe or slight, according to the representation made by a medical witness of the circumstances which rendered the wound mortal; if he neglect to state the full influence of imprudence or excess on the part of the wounded person, where either has existed, over the progress of the wound, he may cause the prisoner to be punished with undue severity. The humanity of our judges is such, that when medical evidence is clear and consistent on a point of this nature, and there are no circumstances in aggravation, they commonly pass a mild sentence. (See case by M. Ollivier, "Ann. d'Hyg.," 1842, p. 128.) The neglect to call in a medical practitioner,

or the refusal to receive medical advice, will not, however, according to the decision in *Reg. v. Thomas* (Gloucester Aut. Ass., 1841), be considered a mitigatory circumstance in favor of the prisoner, even although the wound was susceptible of being cured. A man may receive a lacerated wound of a limb, which is followed by tetanus or gangrene, and thus proves fatal; he may have declined receiving medical advice, or have obstinately refused amputation, although proposed by his medical attendant. This would not operate as a mitigatory circumstance on the part of an assailant, because a wounded person is not compelled to call for medical assistance, or to submit to an operation, while a medical witness could not always be in a condition to swear that the operation would have positively saved his life; he can merely affirm that it might have afforded him a better chance of recovery. Again, a person may receive a blow on the head producing fracture, with great depression of bone and symptoms of compression of the brain; a surgeon may propose the operation of trephining to elevate the depressed bone, but the friends of the wounded man may not permit the operation to be performed. In such a case, his line of duty will be to state the facts to the court, and it is probable that in the event of conviction there would be some mitigation of punishment; because such an injury, if left to itself, must in general prove mortal, and no doubt could exist in the mind of any surgeon as to the absolute necessity for the operation. But the neglect or improper conduct of a person, who receives a wound thus rendered fatal, does not exculpate the aggressor. The crime is either murder or manslaughter.

5. *The cause avoidable but for an abnormal or unhealthy state of the body of the wounded person.*—Wounds which are comparatively slight sometimes prove indirectly fatal, owing to the person being in an unhealthy condition at the time of their infliction. In bad constitutions, compound fractures or slight wounds, which in a healthy person would have a favorable termination, are followed by gangrene, fever, or erysipelas, proving fatal. Here the responsibility of an assailant for the death may become reduced, so that, although found guilty of manslaughter, a mild punishment might be inflicted. The consequence may be, medically speaking, unusual or unexpected, and but for circumstances wholly independent of the act of the accused, would not have been likely to destroy life. In general, in the absence of malice, this appears to be the point to which the law closely looks, in order to make out the responsibility of the accused, namely, that the fatal secondary cause must be something not unusual or unexpected as a consequence of the particular injury. The medico-legal question presents itself under this form: Would the same amount of injury have been likely to cause death in a person of ordinary health and vigor? Men who have suddenly changed their habits of living, and have passed from a full diet to abstinence, are sometimes unable to bear up against comparatively slight injuries, and often sink from the secondary consequences. So a man, otherwise healthy, laboring under rupture, may receive a blow on the groin, attended with laceration of the intestine, gangrene, and death; another with a calculus in the kidney may be struck in the loins, and die in consequence of the calculus perforating the bloodvessels and causing

fatal bleeding or subsequent inflammation. In these cases the effects of the violence must be regarded as something unexpected; it would not have produced serious mischief in an ordinarily healthy person, and hence the responsibility of an assailant becomes much diminished. The crime is undoubtedly manslaughter, but the punishment may be of a lenient description. A defence of this kind will, however, be limited by circumstances. A case is reported, in which a *Dr. Fabricius* was tried at the Old Bailey for the murder of his female servant by striking her a blow behind the ear, whereby a large abscess, situated at that part, was ruptured, and this ultimately caused her death. The chief question on the trial was, whether the deceased had died from the effects of the violence, or from the disease under which she was at that time laboring. The doctor ingeniously urged in his defence that he had struck the blow merely for the purpose of opening the abscess! The jury, however, did not agree in taking this professional view of the matter, and they found him guilty of manslaughter.

It must be evident that there exist numerous internal diseases, such as aneurism, and various morbid affections of the heart and brain, which are liable to be rendered fatal by *slight* external violence. The law, as applied to these cases, is thus stated by Lord Hale: "It is sufficient to prove that the death of a person was accelerated by the malicious act of the prisoner, although the former labored under a mortal disease at the time of the act." (1, 428.) In those cases in which a slight degree of violence has been followed by fatal consequences, it is for a jury to decide, under all the circumstances, upon the actual and specific intention of the prisoner at the time of the act which occasioned death. According to Starkie, "it seems that in general, notwithstanding any facts which tend to excuse or alleviate the act of the prisoner, if it is proved that he was actuated by prepense and deliberate malice, and that the particular occasion and circumstances upon which he relies were sought for and taken advantage of merely with a view to qualify actual malice, in pursuance of a preconceived scheme of destruction, the offence will amount to murder." In most of these cases there is an absence of intention to destroy life, but the nature of the wound, as well as the means by which it was inflicted, will often suffice to develop the intention of the prisoner. An accurate description of the injury, if slight, may afford strong evidence in favor of the accused, since the law does not so much regard the means used by him to perpetrate the violence, as the actual intention to kill, or to do great bodily harm. Serious injury, causing death by secondary consequences, will admit of no exculpation when an assailant was aware, or ought to have been aware, of the condition of the person whom he struck. Thus, if a person notoriously ill, or a woman while pregnant, be maltreated, and death ensue from a secondary cause, the assailant will be held responsible; because he ought to know that violence of any kind to persons so situated, must be attended with dangerous consequences. So, if the person maltreated be an infant or a decrepit old man, or one laboring under a mortal disease, it is notorious that a comparatively slight degree of violence will destroy life in these cases, and the prisoner would properly be held responsible. A wound which *accelerates* death *causes* death, and may therefore render the

aggressor responsible for murder or manslaughter, according to the circumstances. The Commissioners appointed to define the criminal law on the subject of homicide thus express themselves: "Art. 3. It is homicide, although the effect of the injury *be merely to accelerate the death* of one laboring under some previous injury or infirmity, or although if timely remedies or skilful treatment had been applied, death might have been prevented." This is conformable to the decisions of our judges. According to Lord Hale, if a man has a disease which in all likelihood would terminate his life in a short time, and another give him a wound or hurt which hastens his death, this is such a killing as constitutes murder. (Archbold, p. 345.)

6. *Abnormal conditions*.—When an assailant could not have been aware of the existence of a diseased or abnormal condition of parts in the wounded person, the question is somewhat different. In many persons the skull is preternaturally thin, and in most persons it is so in those places corresponding to the glandulæ Pacchioni. In a case of this kind a moderate blow on the head might cause fracture, accompanied by effusion of blood, depression of bone, or subsequent inflammation of the brain and its membranes, any of which causes might prove fatal. In some persons, all the bones of the body are unusually *brittle*, so that they are fractured by the slightest force. Inflammation, gangrene, and death may follow, when no considerable violence has been used; but these being unexpected consequences, and depending on an abnormal condition of parts unknown to the prisoner, his responsibility may not, *ceteris paribus*, be so great as under other circumstances. The condition of the bones can be determined only by a medical practitioner. Facts of this kind show that the decree of violence used in an assault cannot always be measured by the effects, unless a careful examination of the injured part is previously made.

7. *Difficulty of proof in death from secondary causes*.—When a person is charged with having caused the death of another through violence terminating in some fatal disease, the case often admits of a skilful defence, and this in proportion to the length of time after the violence, at which the deceased dies. The disease, it may be urged, is liable to appear in all persons, even the most healthy; or it may arise from causes unconnected with the violence. In admitting these points, it must be remembered that death may be proved to have been indirectly a consequence of the wounds by the facts: 1, that the supervention of the secondary cause, although not a common event, lay in the natural course of things; 2, that there did not exist any accidental circumstances which were likely to have given rise to this secondary cause independently of the wound. The proof of the first point amounts to nothing, unless the evidence on the second point is conclusive.

CHAPTER XXX.

WOUNDS INDIRECTLY FATAL.—TETANUS FOLLOWING WOUNDS.—ERYSIPELAS.—DELIRIUM TREMENS.—GANGRENE.—DEATH FROM SURGICAL OPERATIONS.—PRIMARY AND SECONDARY CAUSES OF DEATH.—UNSKILFULNESS IN OPERATIONS.—PYEMIA.—MEDICAL RESPONSIBILITY IN REFERENCE TO OPERATIONS.—ACTIONS FOR MALAPRAXIS.

Tetanus following wounds.—Tetanus frequently presents itself as a secondary fatal consequence of wounds, especially of those which are lacerated or contused, and affect nervous or tendinous structures. It has often occurred as a result of slight bruises or lacerations, when the injury was so superficial as to excite no alarm; and it is a disease which gives no warning of its appearance. Tetanus may come on spontaneously, *i. e.*, independently of the existence of any wound on the body. Cases have been brought into the London hospitals, in which the only cause of this disease appeared to be exposure to cold or wet, or, in some instances, exposure to a current of air. ("Lancet," Dec. 14, 1844, p. 351.) It is scarcely possible to distinguish, by the symptoms, tetanus from wounds (traumatic) from that which occurs spontaneously as a result of natural causes (idiopathic). In endeavoring to connect its appearance with a particular wound or personal injury, it will be proper to observe—1, whether there were any symptoms indicative of it before the mal-treatment; 2, whether any probable cause could have intervened to produce it, between the time of its appearance and the time at which the violence was inflicted; 3, whether the deceased ever rallied from the effects of the violence. The time at which tetanus usually makes its appearance when it is the result of a wound, is from the third to the sixth day; but it may not appear until three or four weeks after the injury, and the exciting cause may still be traced to the wound which may have healed. When resulting from a wound it is generally fatal.

A medical practitioner is bound to exercise great caution before he pronounces an opinion that a fatal attack of tetanus has arisen either from spontaneous causes, or from slight blows or personal injuries. A rigorous inquiry should be made into all the attendant circumstances. Slight punctured wounds, operating as a cause of tetanus, have been overlooked or only discovered by accident after death, and it is highly probable that many cases have been set down as idiopathic tetanus in which, by proper inquiry, the disease might have been traced to a wound or some personal injury. In one instance the tetanus was at first considered to be idiopathic; but shortly before death a small black mark was observed on the thumb-nail. On making inquiry, it was found that a few days previously to the attack a splinter of wood had accidentally penetrated the thumb. The patient attached so little importance to the accident that he did not

mention the circumstance to his medical attendant. This was no doubt the sole cause of the disease. Two similar cases have been mentioned to me by Dr. G. Johnson. (See "Brit. Med. Jour.," 1872, Nov. 23, p. 594.) Many trials for murder and manslaughter have occurred in this country in which tetanus was the immediate cause of death: and the defence has generally rested upon the probable origin of the disease from accidental causes. In *Reg. v. Ouion*, Gloucester Winter Ass., 1880, the prisoner was charged with the manslaughter of her husband by throwing the leg of a stand at him. The weapon produced a wound in the upper lip which penetrated to the mucous membrane of the mouth. On the third day tetanus appeared, and from this disease the man died. For the prosecution the tetanus was ascribed to the wound, while, on the part of the defence, it was contended that a week before the occurrence the deceased had complained of having run a nail into his foot, and on the night before the first symptoms of tetanus appeared he had slept in wet clothes. Either of these conditions would suffice to produce an attack of tetanus. Under this doubtful state of the medical evidence the prisoner was acquitted.

Erysipelas, like tetanus, may be a fatal result of slight injuries. Wounds affecting the scalp are liable to be followed by this disease. Burns and scalds sometimes prove fatal through this secondary cause. Some constitutions are particularly prone to erysipelatous inflammation, and thus, wounds comparatively slight may have a fatal termination. When a wounded person has died from this disease, an assailant cannot be made responsible for the fatal result, unless the erysipelas is clearly traced to the injury. The medical facts that the person assaulted has never recovered from the effects of the violence, and that the inflammation set up has suddenly assumed an erysipelatous character, are sufficient to establish this connection. If there has been recovery, and an interval of some days has elapsed, a doubt may arise respecting the connection of the erysipelas with the violence inflicted. This disease is occasionally idiopathic, *i. e.*, it appears like tetanus without any assignable cause. In *Reg. v. Jones* (Monmouth Lent Ass., 1873, the prisoner, a collier, was convicted of manslaughter under the following circumstances: Prisoner was fighting with another man, and the deceased, a woman, endeavored to part them. Prisoner fixed his teeth savagely on her thumb and bit her severely. The wound was poulticed. It was not until the fourth day that she had medical advice. Erysipelas had then commenced and had caused great swelling of the limb up to the shoulder. She died in three weeks. The medical evidence was to the effect that she had died of erysipelas from the wound, but the fatal result was in a great measure due to an impaired state of health from excessive drinking. The prisoner was notwithstanding found guilty.

It is sometimes difficult to establish the connection of erysipelas with a wound, especially when the disease occurs some time after its infliction and in a remote part of the body not implicated in the wound. When this connection cannot be distinctly made out, there will be an acquittal.

Delirium tremens is a disease which frequently presents itself as a secondary consequence of injuries in persons of intemperate habits. Whether the injury be slight or severe, this disease may equally supervene and

prove fatal. It is observed occasionally as a consequence of operations required for the treatment of wounded persons. The remarks made at p. 329 upon the influence of unhealthy constitutions on wounds, apply with especial force to cases of this description.

Death from surgical operations.—In the treatment of wounds, surgical operations are frequently resorted to, and a wounded person may die either during the performance of an operation, or from its consequences. A question will thence arise, whether the person who inflicted the wound should be held responsible for the fatal result. The law regards a surgical operation as part of the treatment, and if undertaken *bona fide*, and performed with reasonable care and skill, the aggressor will be held responsible, whatever may be the result. The necessity for the operation, and the mode of performing it will be left to the operator's judgment. As the defence may turn upon the operation having been performed unnecessarily, and in a bungling and unskilful manner, it will be right for a practitioner, if possible, to defer it until he has had the advice and assistance of other practitioners. According to Lord Hale, if death takes place from an *unskilful operation*, performed for the cure of a wound, and not from the wound, the responsibility of the prisoner ceases; but this eminent lawyer does not appear to have considered that death may take place as a consequence of the most skilful operation required for the treatment of a wound, and yet be wholly independent of the wound itself.

If the operation has been performed by the medical witness himself, and the necessity for its performance is questioned by counsel for the prisoner, it is open to the witness to give the requisite explanation in his evidence. It would appear from a case tried before the late Mr. Justice Shee, that the necessity for an operation will not be assumed; but if called in question, it must be proved by witnesses for the prosecution. In *Reg. v. Moreland* (C. C. C., Sept. 20, 1865), the prisoner threw deceased on the ground and fractured his leg. The limb was amputated at the London Hospital, and the man subsequently died. Counsel for the prisoner asked the surgeon from the hospital who spoke to the death of the deceased, whether an operation was really necessary. The witness said he could not tell, as he had not had charge of the case previous to the operation. Counsel then raised the question whether prisoner or the doctors had caused the man's death. The counsel for the prosecution suggested that the court might accept as a fact that amputation would not have been performed had it not been necessary; but the learned judge said that would not do. They must deal with the case on the evidence before them. He then observed to the jury that although undoubtedly amputation would not be adopted at such a place as the London Hospital, without the necessity for it, yet evidence to that effect must be before them on oath. They could not act on what they had every reason to believe; therefore they must acquit the prisoner. The failure of justice in this case rested with those who were concerned for the prosecution. The operator, who could probably have satisfied the court that he had not cut off the wrong leg, and that there were good reasons for performing the operation, was not called as a witness; but

in his place a gentleman was summoned who could not answer these necessary questions.

Death is by no means an unusual result of severe operations, the secondary consequences under which the patient may die being very numerous even when the case is most skilfully managed. Sometimes the patient will die on the table, although but little blood may have been lost. Fear, pain, and sudden shock to the nervous system, have caused death under these circumstances. The most common indirect causes of death after severe operations are secondary hemorrhage, erysipelas, tetanus, delirium tremens, pyæmia, and hectic fever with gangrene of the stump. Mr. Travers observes, that "a pre-existing disease of the liver, kidney, or testicles, though chronic, and in itself not alarming to the constitution, becomes a drag upon its elasticity, and stands in the way of recovery. Inspection of the body after death frequently explains the unfavorable result of operations that promise well, by discovering one or more organs in a state of chronic disease, which had not previously deranged the health in a degree sufficient to give notice of its existence; and which might, therefore, have remained quiet for years to come, had no extraordinary call been made upon the powers of the system." ("On Constitutional Irritation," p. 45, 121, et seq.)

Should an operation be unnecessarily or unskilfully performed, the responsibility of an aggressor would, it is presumed, cease, if the death of a wounded party could be clearly traced to it. Thus, if in carelessly bleeding a wounded person, the brachial artery should be laid open ("Ann. d'Hyg.," 1834, t. 2, p. 445), or if, in performing amputation, a large artery be improperly secured, so that the patient in either case dies from loss of blood, the prisoner could not be equitably held responsible; because it would be punishing him for an event depending on the unskilfulness of a medical practitioner. According to Platt, B., a prisoner will be held responsible, if the original wound were likely to produce death, although unskilfully treated. Supposing the bleeding or amputation to be performed with ordinary care and skill—and yet, in the one case, inflammation of the veins, and in the other erysipelas, tetanus, gangrene, or fever should destroy life, the prisoner will be liable for the consequences. The practice of the law is strictly consistent with justice. Should the operation be considered to be *absolutely* required for the treatment of a wound, which, according to all probability, would prove mortal without it,—should it be performed with ordinary skill, and still death ensue as a direct or indirect consequence, it is only just that the person who inflicted the injury should be held responsible for the result. It is presumed in these cases, that were the patient left to himself he would, in all probability, die from the effects of the wound. If, therefore, a surgeon, knowing that an operation would give a chance of saving life on such an occasion, did not perform it, it might be contended in the defence, that the deceased had died, not from the wound, but from the incompetency and neglect of his medical attendant. Hence it follows that if, during this necessary treatment, unforeseen though not unusual causes cut short life, no exculpation should be admitted, if it went to attack the best-directed efforts made for the preservation of life. (See "Ann. d'Hyg.," 1835, t. 1, p. 231.) If an operation is rendered necessary by reason of

the event of death occurring from these simple operations, the assailant would be held responsible for the fatal result. From cases hitherto decided, it would appear that the law regards three circumstances in death following surgical operations: 1st, the necessity of the operation itself; 2d, competency of the operator; and 3d, whether the wound would be likely to prove mortal without it.

Operations under a mistaken opinion.—It may happen that the wound is not of a mortal nature, and that, although an operation was skilfully performed, it was *not* necessary to save life; in other words, the wounded person may die from the immediate results of a serious operation, performed under a mistaken view of the case. It is well known to surgeons that a cancerous tumor has been occasionally mistaken for aneurism, an artery has been secured, and death has followed. A case occurred in Dublin in 1844, in which the carotid artery was tied; and another in London in 1845, in which the operation was performed on the common iliac artery for supposed aneurisms; in both of these instances, the patients sank, and after death the tumors were proved not to have been aneurismal. The operations were not necessary; they proved fatal, and they had been performed under a mistake. In a case reported by Mr. Syme the carotid artery was tied, and the patient died in a few days from loss of blood. After death it was found that the tumor was not an aneurism, but a cyst containing a thin fluid. ("Dub. Med. Press," Dec. 22, 1847, p. 302.)

Let us assume that a man laboring under a slight aneurismal dilatation of a large artery receives a blow on the part,—the tumor gradually increases, and is mistaken for an abscess by three or four surgeons, whose professional standing would prevent their general competency from being questioned. Under a wrong diagnosis, it is opened, and the patient dies on the spot; in such a case it would be unjust to make the aggressor liable; for, even admitting that the aneurism had resulted from the blow, and that a competent surgeon acted with bona fides, the treatment would be unskilful, and the case would fall under the rule laid down by Lord Hale (ante, p. 327). The real facts, however, may not transpire until after the death of the wounded person; and it may then be alleged by a prisoner's counsel that the operation was not necessary to save life, and that the wounded man might have recovered without it. From the ruling of our judges on various occasions in which this question has arisen, it would appear that the relative degree of skill possessed by medical men is not a question for a jury in a criminal case; although in a civil case, as in an action for malapraxis, the whole of the medical facts are invariably submitted to their judgment. This difference can only be justified by the assumption, that a man who inflicts a wound must take all the consequences—good or bad. No operation would have been required but for the injury, and the prisoner ought not to escape on account of want of skill in a surgeon, or of a mistake made by a skilful operator. It was decided in the cases of *Rex v. Quain* and *Rex v. Pym*, that although the indictment alleged that the deceased died of the wound, while in fact he died from the results of an operation, yet it was good in point of law.

When a wounded person is taken to a hospital in which gangrene or

erysipelas is diffusing itself by infectious propagation, and he is attacked by one of these diseases, before or after the performance of an operation, and dies, a prisoner may be held responsible for the fatal result. It might be contended that the transportation of the wounded man to such a locality was not absolutely necessary for his treatment or for the preservation of his life, and that he would not have died but for the accidental presence of an infectious disease. Cases of this kind cannot be easily determined by any general rules.

Pyæmia.—In addition to erysipelas and tetanus, there is another cause of death which is liable to follow personal injuries and operations, namely *pyæmia*, or the introduction of pus into the blood by absorption or by mouths of divided bloodvessels. The purulent matter appears to act as a poison, and one of its marked effects is to coagulate the blood either in the large vessels or in the capillaries. According to Dr. Wilks' observations *pyæmia* is seldom observed after superficial injuries during the process of healing, or after wounds resulting from simple operations; but it occurs frequently when a bone is involved, either from the injury or as the result of an operation. Inflammation of the cellular membrane surrounding bone is a condition highly favorable to its occurrence. It has been stated that the cause of death in one-half of the cases of amputation is *pyæmia*. (See a paper on this subject by Dr. Wilks, "Guy's Hospital Reports," 1861, p. 119.) The medical witness must remember that *pyæmia*, like tetanus and erysipelas, may arise from causes totally irrespective of wounds or personal injuries. (Cases by Dr. Habershon, "Guy's Hospital Reports," 1859, p. 179.)

Questions relative to responsibility in death following operations would come more frequently before courts of law, were it not that the cases are stopped in the coroners' courts by verdicts of accidental death. (See "Med. Gaz.," vol. 19, p. 157.) It unfortunately happens that on these occasions there is a great difference of opinion among medical witnesses respecting the connection of the disease with the death, and indeed the necessity for the operation itself. The evidence of opinion in favor of the prosecution is sometimes exactly balanced by that urged in the defence, and under these circumstances, the only course open to the court is to direct an acquittal. Differences of opinion upon these subjects among members of the profession tend to convey to the public the impression that there are no fixed principles upon which medical opinions are based, and, consequently, that it would be dangerous to act upon them. Thus it is that we are accustomed to hear of a medical prosecution and a medical defence, as if the whole duty of a medical jurist consisted in his making the best of a case, on the side for which he happens to be engaged,—adopting the legal rule for suppressing those points which are against him, and giving an undue prominence to others which may be in his favor! This is an unfortunate condition of things, for which at present there appears to be no other remedy than that of appointing a Medical Board of competent persons to act as assessors to the learned judge, to whom such questions should be referred, in the same manner as questions relative to navigation are referred by the Admiralty Court to a Board formed of members of the Trinity House,—professionally acquainted with the matters in dispute.

Medical responsibility for operations. Malapraxis.—This is a very wide subject, but it can here be only glanced at in a few of its leading features. It was held by Lord Ellenborough, that if a person acting in a medical capacity be guilty of misconduct arising either from gross ignorance of criminal inattention, by which a patient dies, he is guilty of manslaughter. Faults, such as omissions, or errors in judgment to which all are liable, are not visited with this amount of criminality. The same rule applies to the licensed as to the unlicensed practitioner; but it would appear, from the charge of Williams, J. (Winchester Spring Ass., 1847), that a degree of unskillfulness which might lead to the conviction of a licensed, would justify the acquittal of an unlicensed person. This was in the case of a midwife, aged 72, alleged to have caused the death of a woman on whom she had been called to attend. "The charge," said the learned judge, "appeared to be that by want of skill or attention to her duties, she had caused the death of the woman upon whom she was attending. In order to constitute this offence, it must be shown that the party was guilty of criminal misconduct, either arising from gross ignorance or want of skill, or gross inattention. With respect to the degree of want of skill, he must say, that it was not to be expected that a midwife, who was called in to attend a person in the humble class of the deceased, a soldier's wife, should exhibit what a regular medical practitioner would call competent skill. It was enough if she applied that humble skill which, in ordinary cases, would lead to a safe delivery. She was *not* bound to have skill sufficient to meet peculiar and extraordinary exigencies, although in the case of a regular medical man, such skill might be required. The class of this humble practitioner was absolutely necessary for the poorer classes, and, although on the one hand it was fit the law should protect a patient by punishing a person for gross want of skill, yet he thought there would be much to be lamented if it was applied with such severity as to render a party not possessing skill of this kind liable to punishment for manslaughter!"

Charges of manslaughter have frequently been brought against medical practitioners in cases of midwifery. In some instances gross mismanagement has been proved: the uterus, and even parts of the viscera, have been torn away, and in such cases convictions have very properly followed. It is well known, however, that much difference of opinion exists among the most eminent practitioners of midwifery respecting the treatment to be pursued in certain cases of difficulty, as where the after-birth presents (placenta prævia). There are eminent accoucheurs who advise in this case entirely opposite modes of practice, and who look upon that pursued by the other as of the most dangerous kind. When death is really not a result of the medical treatment, an action for damages may be brought against the practitioner on a charge of *malapraxis*. From the evidence given on some of these occasions, it appears that an action of this kind is occasionally resorted to as a very convenient way of settling a long account.

It has been a question whether slight deviations from the ordinary mode of performing operations should involve a medical man in a charge of *malapraxis*. I am not aware that this question has been raised in England; but a remarkable instance occurred in the United States a

few years since, in which an action was brought and damages were recovered against a medical man for alleged negligence in vaccinating a young woman (case of *H. L. Landon*). Some inflammation of the skin followed the operation, which, it was alleged, was performed nearer to the elbow-joint than usual. The plaintiff soon recovered from the effects. The most singular feature of this case was the ruling of the judge. He is reported to have said: "In performing the operation of vaccination or inoculation, the physician is liable for all consequences if he neglects the usual precautions, or fails to insert the virus in that part of the arm *usually selected* for the purpose; notwithstanding many other parts of the body might be proved to be equally proper and even more suitable locations!" If this be law, it is a very singular specimen of transatlantic jurisprudence. It might as well be ruled that legs should always be amputated at the same spot; and in case of neglect of this rule, that the operator should be made responsible for the result.

When on these occasions there is a division of opinion among men of equal experience respecting the necessity for an operation or the proper performance of it, a practitioner who is defendant, has a right to expect that a verdict will be returned in his favor; since it is not to be supposed that, in order to recover payment for a bill, or to answer a charge of unskilfulness, a man's practice should receive the unanimous approval of the *whole* of his professional brethren, especially in cases in which there is an acknowledged difference of opinion respecting the treatment. On this showing, a man would never be able to recover his charges for the treatment of a case of severe burn or scald; since some practitioners consider it malapraxis to adopt the stimulating, while others equally regard it as malapraxis to adopt the cooling plan of treatment! All that appears to be expected is a reasonable accordance in treatment with received professional doctrines.

CHAPTER XXXI.

CICATRIZATION OF WOUNDS.—EVIDENCE FROM CICATRICES.—CHANGES IN AN INCISED WOUND.—IS A CICATRIX ALWAYS A CONSEQUENCE OF A WOUND?—ARE CICATRICES WHEN ONCE FORMED INDELIBLE?—CHARACTERS OF CICATRICES.—THEIR AGE OR DATE.—CICATRICES FROM BLEEDING, CUPPING, SETONS AND ISSUES.—CICATRICES FROM BURNS.—CICATRICES FROM DISEASE DISTINGUISHED FROM THOSE OF WOUNDS.

Cicatrization of wounds.—The time at which a particular wound was inflicted may become a medico-legal question, both in relation to the living and the dead. The identity of a person, and the correctness of a statement made by an accused party, may be sometimes determined by an examination of a wound or its cicatrix. So if a dead body be found with marks of violence upon it, and evidence adduced that the deceased was maltreated at some particular period before his death, it will be

necessary for a practitioner to state whether, from the appearance of the injuries, they could or could not have been inflicted at or about the time assigned. A case was tried at the Taunton Spring Assizes, 1841 (*Reg. v. Raynon*), wherein evidence of this kind served to disprove a statement made by the accused. The prisoner was charged with maliciously cutting and wounding the prosecutrix. There was a cut upon his thumb, which he accounted for by saying it was from an accident that had occurred three weeks before. The medical witness declared, on examining it, that it could not have been done more than two or three days, which brought the period of its infliction to about the time of the murderous assault. This with other circumstances led to a conviction.

An incised wound inflicted on the living body gradually heals by adhesion, when no circumstances interfere to prevent the union of the edges. For eight or ten hours the edges remain bloody—they then begin to swell, showing the access of inflammation. If the parts are not kept well in contact, a secretion of a serous liquid is poured out for about thirty-six or forty-eight hours. On the third day this secretion acquires a purulent character. On the fourth and fifth days, suppuration is fully established, and it lasts five, six, or eight days. A fibrous layer, which is at first soft and easily broken down, then makes its appearance between the edges of the wound: this causes them gradually to unite, and thus is produced what is termed a *cicatrix*. Cicatrization is complete about the twelfth or fifteenth day if the wound is simple, of little depth and width, and affecting only parts endowed with great vitality. The length of time required for these changes to ensue will depend—1. On the situation of the wound; wounds on the legs are longer in healing than those on the upper part of the body. If a wound is situated near a joint, so that the edges are continually separated by the motion of the parts, cicatrization is retarded. 2. On the extent; a deep or wide wound is long in undergoing cicatrization. Wounds involving many and different structures are also longer in healing than those simply affecting the skin and muscles. 3. On the age and health of the wounded person; the process of cicatrization is slow in old persons as well as in those who are diseased and infirm. In an incised wound the cicatrix is generally straight and regular: but it is semilunar if the cut is oblique. It has been said that the cicatrices of incised wounds are rectilinear, but this is not always the case; in general, they are more or less elliptical, being wider in the centre than at the two ends—this appears to be due principally to the elasticity of the skin and the convexity of the subjacent parts: thus it is well known that in every wound on the living body the edges are more separated in the centre than at the ends, and this physical condition influences the process of cicatrization. When the wound is in a hollow surface, or over a part where the skin is not stretched, as in an armpit or groin, then the cicatrix may be rectilinear, or of equal width throughout. If there were any loss of substance in an incised wound, or if the wound were lacerated or contused, the cicatrix would be irregular, and the healing would proceed by granulation. The process might then occupy five, six, or eight weeks, according to circumstances. When healed, the cicatrix would be white, and if there had been a loss of substance it would be depressed and present a

puckered appearance; the surface of the skin would be uneven. (See an essay on this subject by Dr. Krügelstein, Henke's "Zeitschrift der S. A.," 1844, b. 2, s. 75.)

Is a cicatrix always a consequence of a wound?—Assuming that the term wound implies a breach of continuity affecting the layers of the true skin (cutis), a cicatrix is always produced in the process of healing. Slight punctures or incisions with a lancet, and even leech-bites, affecting only the surface of the cutis, may leave no trace after a few weeks or months. In an even cut made by a very sharp instrument, especially if it is in the direction of the fibres of subjacent muscles, and the parts are kept in close contact, the cicatrix is even, linear, and sometimes so small as to be scarcely perceptible; and if the skin is white, it may be easily overlooked. Wounds of this kind are not, however, commonly the subject of medico-legal inquiry. If, on examining a part, where at some previous time a stab, cut, or burn involving the cutis is alleged to have been inflicted, we find no mark or cicatrix, it is fair to assume that the allegation is false, and that no wound has been inflicted, making due allowance for the fact that mere abrasions of the cuticle, or very slight punctures and incisions, often heal without leaving any well-marked cicatrices.

A trial took place at the Old Bailey in 1834, in which the late Mr. Carpue was able to rescue a man who was wrongly charged with being a convict, and with having unlawfully returned from transportation. The chief clerk of Bow Street produced a certificate, dated in 1817, of the conviction of a person alleged to be the prisoner, under the name of Stuart. The governor of the gaol in which Stuart was confined believed the prisoner to be the person who was then in his custody. The guard of the hulks to which Stuart was consigned from the gaol, swore most positively that the prisoner was the man. On the cross-examination of this witness, he admitted that the prisoner Stuart, who was in his custody in 1817, had a wen on his left hand, and so well marked was this, that it formed a part of his description in the books of the convict-hulk. The prisoner said his name was *Stipler*; he denied that he was the person named Stuart, but from the lapse of years he was unable to bring forward any evidence. The Recorder was proceeding to charge the jury, when the counsel for the defence requested to be permitted to put a question to an eminent surgeon, Mr. Carpue, who happened accidentally to be present in court. He deposed that it was impossible to *remove such a wen as had been described without leaving a mark or cicatrix*. Both hands of the prisoner were examined, but no wen, nor any mark of a wen having been removed, was found. Upon this, the jury acquitted the prisoner. It is highly probable, however, that but for the accidental presence of Mr. Carpue, the prisoner would have been convicted and transported for life, from the unfortunate resemblance which he was supposed to bear to the real convict, Stuart.

The cicatrices resulting from wounds after the performance of *surgical operations* are commonly well indicated by their regular form and their situation. They may present the characters of punctured or incised wounds, or a mere division of parts for the excision of tumors. As the healing process is assisted by art, the cicatrices are commonly marked by

great regularity. The identity of a living person, or of a dead body, may be proved by the existence of a cicatrix which has been the result of a surgical operation. There can be no pretence for saying that such cicatrices, when they have involved the true skin, disappear. Whether the arm is wrinkled or unusually fat, the cicatrix may be found if it has ever existed.

A case in which this question respecting the permanency of cicatrices from wounds was raised, was referred to me under the following circumstances. (*Reg. v. Henry Reed and Elizabeth Donelan*, Chelmsford Spring Ass., 1842.) The medical evidence was to the effect that "there was a wound on the nose of the prosecutrix, apparently inflicted by some sharp instrument, and the bridge of the nose was broken down. The weapon had entered half an inch, and had caused profuse bleeding. The wound was so deep that if it had entered a little higher up, in the eye, it might have caused death." In the defence it was urged that no weapon had been used, and that although the male prisoner had struck the prosecutrix a blow, the female prisoner had taken no share in the assault. It does not appear that any medical evidence was called to show in what state the prosecutrix was at the time of the trial. It was assumed that a weapon must have been used, and the prisoners were convicted, the one of stabbing and the other of aiding and abetting. About six months after the alleged stabbing, and some weeks after the prisoners had been convicted and sentenced to punishment, the face of the prosecutrix was examined by two surgeons (one of them a practitioner of twenty-eight years' standing), and they both deposed that there was no mark of a cicatrix from a stab, or fracture of the nose, or of any personal injury whatever. Other surgeons were requested to examine the face of the prosecutrix, but this she declined permitting; and as there was no power to compel her, the medical facts of the case were referred to Professor Quain, Mr. Guthrie, Mr. Key, and myself. The evidence of the surgeons at the trial was laid before us, with the statements of the two surgeons who subsequently examined the prosecutrix. We all agreed that if such a wound as that described in the medical evidence had been inflicted, there would have been a visible cicatrix and a ridge or prominence indicative of the situation where the bridge of the nose was stated to have been broken; and as no such marks could be perceived by two well-informed surgeons, we considered it improbable either that such a wound as that described could have been inflicted, or that a weapon could have been used in the assault. The question really to be decided was—Could all traces of such a wound as that above described, be effaced in a period of six months, or even during the life of a person? Either the wound must have been misdescribed, or some marks of its past existence in the form of a cicatrix would unquestionably have been found. In *Barnett v. Roberts* (Court of Exchequer, Nov. 1867), an action was brought by plaintiff, a surgeon, for injury resulting from an assault by the defendant. It appeared from the evidence that the defendant struck the plaintiff two violent blows on the head with the handle of his umbrella. It was alleged that this had caused a fracture of the skull, and had produced a long and painful illness. Mr. Erichsen and Dr. F. Winslow gave evidence for the plaintiff to the effect that in their judgment the skull was

fractured, the brain organically injured, and the plaintiff's recovery rendered practically hopeless. On the other hand, for the defence, the late Mr. Partridge and Mr. Wood, with other witnesses, deposed that the skull was not fractured, and that the depression supposed to indicate the fracture was congenital, and not the result of a blow or accident. A skull with a natural depression in it was produced, and shown to the jury. The plaintiff's head was examined in court by Mr. Partridge. He could feel no cicatrix in the alleged seat of injury, but there was a thickening over the depression. On this evidence the jury could not agree. There would be no difficulty in such a case if a careful examination was made soon after the assault; but when surgical opinions are taken some weeks or months afterwards, the witnesses are not likely to agree. Even if there had been a cicatrix on this occasion, this would not have proved that the skull had been fractured. The injury to the brain might well have been a result of the violence, although there had been no fracture.

Characters of cicatrices. Their age or date.—In an early stage a cicatrix is softer and redder than the surrounding skin, but after some months or years, it becomes white, hard, smooth, and shining. The fibrous substance of which it is formed receives less blood than the uninjured skin; hence, on compressing the skin around an old cicatrix, its situation and form are well marked by reason of the blood not readily entering into it on removal of the pressure. As the age of a cicatrix increases, it becomes smaller, thicker, whiter, more shining and less sensitive. It is fibrous in structure, dense, without sebaceous follicles, adipose cells or hairs, and it contains but few absorbents and exhalants. The time required for these changes to take place cannot be defined. In one person they may be observed in a few months, and in another only after some years. The tissue of which an old cicatrix is formed, is different from that of the skin; it is harder, contains less blood, and is destitute of any colored pigment, so that its whiteness, which is remarkable on the cicatrized skin of a negro, is retained through life. If any cicatrices were easily obliterated, it would be those which are even and regular—the results of incised wounds by sharp instruments; but I have observed that cicatrices of this kind have certainly retained their characters unchanged in one instance for twenty, and in another for twenty-five years. According to the observations of Dupuytren and Delpech, the substance of a cicatrix is not converted into true skin—it never acquires a rete mucosum, *i. e.*, the membrane which gives color to the skin. Although this is generally true of incised and punctured wounds, yet contused and lacerated wounds on the legs of persons advanced in life, frequently present a brown discoloration from the deposit of a brown pigment. In the cicatrices of lacerated and contused wounds, the form of the weapon with which the wound was inflicted is sometimes indicated. It is not, however, easy to distinguish the cicatrix of a stab of old date from that produced by a pistol-bullet fired from a distance. In both cases the edges may be rounded and irregular, and the cicatrix puckered, unless the stab has been produced by a broad-bladed weapon. If no mark of cutting can be perceived within a few months of the period at which a severe wound is alleged to have been inflicted, it is reasonable

to infer that there has been some mistake, or that the circumstances have been greatly exaggerated. Cicatrices grow or increase in size during the process of growth. Mr. Adams found, in the case of an infant who had been operated on, a cicatrix doubled in length and greatly increased in width after eighteen years. Vaccination scars in the adult are frequently seen from one-half to three-quarters of an inch in diameter, the increased size from the original puncture arising from the growth of the cicatrix. ("Brit. Med. Jour.," Dec. 1873, p. 684.) Sir James Paget has made a similar observation. The growth takes place *pari passu* with the body. ("Lectures on Pathology," vol. 1, p. 49.)

It is important to observe that all cicatrices are of smaller size than the original wound, for there is a contraction of the skin during the process of healing. This is especially noticed with regard to the cicatrix of a *stab*, which is frequently of a triangular form. A recent stab, owing to the elasticity of the skin, is smaller than the weapon; and the resulting cicatrix is always smaller than the wound. Hence it is difficult to judge of the size of the stabling instrument from an examination of an old cicatrix. Cicatrices arising from a loss of substance in the cutis, or true skin, are usually indicated by a depression. In gunshot wounds, if the projectile has been fired from a distance, the cicatrix is of smaller dimensions than the ball. It represents a disk depressed in the centre, and attached to the parts beneath, while the skin is in a state of tension from the centre to the circumference. The amount of depression is great in proportion to the quantity of cellular membrane beneath. If the bullet has been fired near to the body, the cicatrix is large, deep, and very irregular. In this case there may be the bluish marks of tattooing from the gunpowder carried into the skin. If the projectile has made two apertures, the aperture of exit is known by the greater size and irregularity of the cicatrix. (See "Ed. Monthly Journ.," 1854, 10, 370.)

There are no appearances in a cicatrix which will allow us to fix the *date* at which the wound leading to its production was inflicted, and it is often most difficult to say how or by what means it was inflicted. If the person is living, he may give a description of the injury and the date of its production, which may be consistent or inconsistent with the appearances presented. As Caspar justly remarks ("Ger. Med.," 1, 115), it requires more than two, three, or four weeks to produce the hard white shining appearance of an old cicatrix; but when it has once acquired these characters, there are no medical data for enabling us to determine whether the injury was inflicted two, three, or even ten years before. A proper attention to the number, situation, and appearances presented by cicatrices on the living or dead body, will, however, sometimes enable a medical witness to establish or disprove the identity of persons.

Cicatrices from wounds or disease. Imputed.—As there are imputed wounds, so there may be imputed cicatrices. It is rare to hear of frauds of this description; the wound must be made in anticipation at a long date in order to give the appearance of an old cicatrix—the part wounded must be selected in order to carry out the fraud, and the person producing the wound may carry the incision or puncture too deeply or too superficially, and thus lead to detection. It is more likely that an impostor may seek to gain his object either by attributing the cicatrices of

wounds accidentally received to other causes, or by ascribing cicatrices which have resulted from disease, to some particular cause occurring in early life. By a remarkable coincidence, two persons may have cicatrices on or about the same part of the body, produced by cuts, punctures, or abscesses in early life; and serious mistakes may be made under these circumstances. A case is reported to have occurred in France in 1794, in which a man named *Lesurgues* was tried, convicted, and executed for robbery and murder. There were some doubts at the time as to his identity, and strong exertions were made to save his life. Soon after his execution the real murderer was discovered, between whom and *Lesurgues*, who had no hand or part in the crime, there existed a wonderful resemblance in stature, complexion, and features. But the most extraordinary part of the case was that *Lesurgues*, like the real criminal, had a cicatrix or scar on the forehead, and another on the hand; and there is no doubt that these points of resemblance, which upon a proper scientific examination might have been proved to be really different, became the turning-point of the case, and led to the conviction of an innocent person. Thus, a vulgar impostor with old scars upon his person, may make use of them as proofs of identity. Such scars may really exist: they may be clearly proved to be of old date, and they may be assigned to causes which cannot be disproved except by a close medical examination. The scars or cicatrices may have arisen from scrofulous ulcers or abscesses, in which case it would not be difficult to distinguish them from the cicatrices of wounds. In the case of *Smyth v. Smyth* (Gloucester Summer Ass., 1853), the plaintiff claimed to be the rightful heir to certain estates occupied by the defendants. He based his claim upon some deeds (alleged by the defendants to have been forged), in which it was stated that the lost heir to these estates would be known by certain marks on his right hand and wrist, suggested to have been received at the time of his birth in 1797, by reason of his having been brought into the world with instruments! It was one of the curious features of this extraordinary case of imposture that no medical opinion was taken or required by the claimant on the probable nature and origin of these marks. When requested at the trial to show his hand to the jury, the mark had the appearance of a puckered cicatrix from a scrofulous ulcer near the wrist. Similar marks from scrofulous sores were seen upon his neck. His statements regarding himself, and the circumstances on which he based his claim, were so improbable and contradictory that the case speedily broke down. A question of this kind may occasionally present some difficulty, but a close examination of the cicatrix, with a consideration of the statement of the person on its mode of production, will enable a practitioner to arrive at a satisfactory conclusion respecting its origin. *Scrofulous* ulcers are generally observed to leave irregular and deeply-furrowed cicatrices, with smooth depressions, surrounded by hard and uneven margins. According to *Schneider*, the *scorbutic* cicatrix is at first dark, bluish-red in color, soft to the touch, somewhat raised and rather painful; in the course of time it becomes flatter, of a reddish-brown color, approaching to green (?) in the centre, very thin and easily injured. *Syphilitic* cicatrices are characterized by great loss of substance; they approximate the margins of

the deep ulcers before their granulations have had time to reach the surface. *Glandular* cicatrices are irregularly tumefied, generally deep, hardened, and of a reddish-brown color. These varieties cannot easily be mistaken for the cicatrices of wounds; but it is not so easy to distinguish them from each other. M. Malle remarks that the form and shape of the cicatrix depend less on the cause producing it than on its anatomical position. The elasticity of the skin, the looseness or density of the cellular tissue beneath, the depression or convexity of the surface and the tension of the muscles, are circumstances which will modify the form of the ulcer and the cicatrix proceeding from it. ("Ann. d'Hyg.," 1840, 1, 430.) An expert can seldom do more than distinguish the cicatrices of ulcers arising from morbid causes, from those which have resulted from violence. Cicatrices in the inguinal regions raise a presumption that they are of *syphilitic* origin, but it is impossible to say that they may not have been derived from simple abscesses. The cicatrices of *scrofulous* ulcers have some resemblance to those produced by fire-arms, but it may be presumed that they are of a scrofulous origin when they are situated in the region of the neck, below the jaw, or in the course of the parotid gland, especially when there is any enlargement of the neighboring glands. A puckered and folded state of the skin around the cicatrix would confirm this opinion.

Cicatrices from bites of animals.—In a recent case, Dr. Coutagne, of Lyon, was able to give evidence of identity by the cicatrices produced on the person of a man charged with assault and highway robbery by the bite of the prosecutor's dog. There was a difficulty in the case, from the fact that the man alleged that he had been bitten some time previously by another dog. Dr. Coutagne satisfied the court that the marks were caused by the prosecutor's dog at the time of the robbery. The man was convicted and sentenced to the galleys for life. ("Ann. d'Hyg.," Dec. 1879, p. 508.)

Is a cicatrix, when once formed, ever removed, or so altered by time as to be no longer recognizable?—This is a question which sometimes presents itself to a medical jurist both in civil and criminal proceedings. When a cicatrix has been produced by the healing of a wound involving a loss of substance in the cutis or true skin, it is permanent. In wounds involving the whole substance of the skin, the cicatrix which is once formed does not disappear, although it may undergo some changes and become less distinct in after life. Wounds which heal by suppuration and granulation generally leave behind them cicatrices which remain for life. The marks arising from the pustules of vaccination, smallpox, herpes zoster, and those produced by setons and issues, leave cicatrices easily recognizable at any period. Cicatrices of wounds made after the completion of growth do not increase in size; they retain the same proportions through life. When the substance of the skin has been penetrated, it retracts, owing to the yellow elastic fibrous tissue which it contains, and the gap thus made is filled up with white fibrous or cicatrix tissue, which forms a marked contrast with the surrounding skin. This may be seen in the cicatrices of the apertures made by bleeding, or in the scars left by herpes zoster. This cicatrix tissue or

connective tissue, as it is called, when once formed is permanent. It never wears out or wastes.

A man may allege, in proof of his identity, that at a former period of his life he was bled in the arm, or foot, or in the temporal artery; that he had undergone cupping, or that he had had a seton or issue in his arm. The simple questions for a medical witness will then be: Are the marks left by these operations present? Are they visible in the situations in which such operations are usually performed? Do they present such cicatrices as would be likely to result from the alleged operations? If not visible at the time of examination, is it or is it not probable that they may have spontaneously disappeared by lapse of time? These simple questions may carry with them momentous issues, either in a civil or criminal case.

With regard to *cupping*, when the operation is properly performed, the numerous small and slightly elliptical cicatrices are well indicated by their whiteness and symmetrical position. The cicatrix left by the use of the lancet in *bleeding* from a vein in the arm or foot, is similar to that of cupping—white, linear, slightly elliptical, with its length in the direction of the vessel, and not across it. About fifty years ago, bleeding from the arm was a frequent operation, the same person requiring to be bled at spring and fall. The cicatrices that resulted were always perceptible; in some instances, when the person had been bled several times in or near the same part of the vein, a hard or knotted white cicatrix was produced, rising above the level of the skin. There is no reason to believe that such a mark, involving as it does the whole cutis, ever disappears. Dr. Beck quotes the case of a child, which had been bled in the right arm when sixteen months old. When nearly four years old the child was lost, and two years subsequently the godmother, seeing two boys pass, was struck with the voice of one of them; she called him to her, and was convinced that it was her lost godson. The identity was also considered to be proved by the discovery of a cicatrix from bleeding in the right arm, and a cicatrix from an abscess in the left knee, both of which were present in the lost child, and also in the one that was found. The latter, however, had upon his body marks of the smallpox, while no marks of this kind were on the body of the former. The child was claimed by a widow (*Labrie*), and many witnesses deposed that it was really her son. The court decided in her favor, chiefly on the ground that the lost child was not marked with the smallpox. (“Med. Jur.,” vol. i. p. 655.) It was admitted that this child had, in the arm and knee, cicatrices similar to those which were known to exist in the one that was missing, and had the medical witnesses agreed about the causes of them, it is probable that the decision would have been different. The cicatrix at the knee was ascribed to the use of caustics by some of the surgeons, and to a slight abrasion by others. The widow *Labrie* admitted that her child had never been bled in the arm, while the missing child had certainly undergone this operation; but on so simple a question as the presence of a cicatrix from bleeding, there was a conflict of medical opinion! Three surgeons examined the cicatrix, and declared that it had been made with a sharp instrument. Others deposed that it was not a cicatrix from bleeding, but from the opening of an abscess.

As the child had been missing two years, it might have had the smallpox in the mean time. If a proper examination of the two cicatrices had been made by medical assessors appointed by the court, this conflict of medical opinion would not have arisen, and the decision might have been different.

According to Casper, the cicatrix left by venesection may sometimes disappear, although he adduces no fact in proof of it ("Gericht. Med.," vol. i. p. 113), while all surgical experience is, I believe, decidedly against it. Devergie correctly states that every wound which involves the thickness of the skin (*cutis*), leaves a cicatrix which is indelible. ("Médecine Légale," vol. ii. p. 217.) According to him, it may become less distinct by time, but it never entirely disappears. In all contested cases of this kind, where there is ample room for a difference of opinion, it would be more satisfactory to take the evidence of skilled medical assessors appointed by the court, than to receive that of medical men specially selected by solicitors to uphold their different views of the case. This would be giving its true value to medical testimony, in aiding, by a proper interpretation of physical signs, to clear away the doubts which necessarily arise by trusting to a supposed remembrance of features, voice, and gesture, after a lapse of many years.

The parts selected for *setons* or *issues* are generally about the shoulder or the nape of the neck. The situation of the cicatrices might thus serve to throw some light on their origin. The cicatrix left by an *issue* cannot be mistaken for the cicatrix caused by a *seton*. In the first place, it is single, depressed below the level of the skin, and rounded in its margin, and, as in all cases in which the cutis is destroyed, it remains as an indelible mark. It is impossible by any process to restore to the skin its uniformity and evenness of surface. M. Malle has pointed out that the double cicatrix which is left by the application of a *seton* may present an appearance which might be mistaken for the entrance and exit-apertures of a bullet, since in both cases a band of hardened lymph may be felt between the two cicatrices. When a hard band of connection cannot be felt between them, the marks cannot be owing either to a bullet or a *seton*, but they may be due to a bite, or to separate wounds produced in the skin at or about the same time.

With respect to *blisters*, they produce only a superficial and temporary injection of the cutis. They do not commonly leave a scar, unless their irritant action has extended to the substance of the cutis, and has led to ulceration and suppuration; the ulcerated being separated from the non-ulcerated portions of the skin, and indicated, according to Dupuytren, by an indelible brown mark.

The cicatrices left as a result of the application of the true *vaccine* lymph have a peculiar irregular honeycombed appearance, with white streaks slightly depressed below the level of the surrounding skin. The spurious vaccine mark is of a reddish color, not depressed, and not presenting the honeycombed appearance and white streaks of the cicatrix of the true pustule. As branding has been abolished in the army there is now a difficulty in determining the identity of soldiers who have deserted from the ranks. The Duke of Cambridge has suggested that vaccination should be performed on all entering the army in a particular situa-

tion and in a particular way, so as in future to mark the identity of the soldiers by the form and situation of the cicatrix.

The scars produced by *smallpox* are in the form of deep depressions, showing a complete destruction of the cutis.

Independently of the cicatrices from local injury, these cases of contested identity may present other physical signs, such as *moles*, *nævi materni*, and other congenital defects to which ordinary witnesses may be able to testify. There can be no fallacy of memory touching the form, size, and position of such marks, and they differ from cicatrices in this—they cannot be artificially imitated. They may, it is true, be removed, but only by actual cautery or caustic applications. If thus removed, a cicatrix is left in the skin, which is indelible. A case is reported by Dr. Beck in which a girl, *Salomé Muller*, had been sold as a slave, but her identity as the child of German parents was proved after fifteen years by two marks resembling moles about the size of coffee-grains on the inside of the thighs. They were proved to have existed in the child, and they were proved to exist in the same parts of the body of the girl eighteen years afterwards. After much litigation, she was, upon this evidence, pronounced to be a free woman. (“*Med. Jur.*,” vol. i. p. 662.)

Cicatrices from burns.—This subject has been fully investigated by M. Malle, of Strasburg. (“*Ann. d’Hyg.*,” 1840, 1, 422.) A superficial burn in healing produces a broad irregular cicatrix, varying with the form of the burning body. If the burn has extended to some depth below the cutis, the cicatrix is deep and has a rounded margin; but in the depression, it is irregular and contracted in proportion to its depth. Caustic solids produce cicatrices with regular edges, as the corrosive substance easily penetrates uniformly through the deep layers of the skin. Caustic liquids produce only superficial marks unless they have been allowed to penetrate deeply, when by the destruction of parts they may give rise to deep and irregular cicatrices. When the cutis is destroyed, an indelible cicatrix remains, whether it is the result of a burn from a heated solid, or from the chemical action of a highly corrosive liquid. In a case in which the strongest nitric acid was applied to the skin for the removal of a mole, the cicatrix produced was visible after twenty-five years, and will no doubt continue for life.

The subject of cicatrices as they are found in the neck, whether arising from wounds, scrofulous disease, or burns, has been fully examined by Dr. Güterbock, of Berlin, in an elaborated paper published in Eulenberg’s “*Vierteljahrsschrift*” for 1873, 2. p. 84.

CHAPTER XXXII.

MEDICAL EVIDENCE OF IDENTITY FROM COLORED CICATRICES OR TATTOO-MARKS.—MODE AND DATE OF PRODUCTION.—DURABILITY OF THESE MARKS.—THEIR ALLEGED SPONTANEOUS DISAPPEARANCE.—CASES OF IDENTITY FROM TATTOOING.—SIMULATED MARKS.—TATTOO-MARKS ON THE DEAD.—MEDICAL RESPONSIBILITY.

THE subject of tattooing has been noticed by medical jurists. Several trials have occurred of late years in France and Germany, which show the great importance of this subject in cases of contested personal identity. The *Tichborne case*, which occupied our law courts for nearly two years, involved some issues of importance in relation to identity from cicatrices, and the marks of tattooing. (See papers by Dr. Tardieu, "Ann. d'Ilyg.," 1855, 1, 171; also, by Dr. Horteloup, in the same journal, 1870, vol. 2, p. 440; and Casper's "Gerichtliche Medicin," vol. 1, p. 115, 1857.) The presence of tattooed or colored marks on the skin of a person, verified by a competent observer, may become the strongest possible proof of identity, and their proved absence, if not accounted for or explained, may furnish the most convincing evidence of non-identity. An escaped convict may allege that he never was tattooed. There may be no colored marks on his skin, but a medical expert may be able to demonstrate that there have been such marks, and that traces of them still exist. A man who is found to be tattooed may, in order to escape punishment, pass himself off as another person also tattooed. In this case medical evidence must be derived from a comparison of the color, form, and situation of the marks in the two. A tattooed man may claim an estate, and adduce the tattoo-marks as a proof of his identity. It would be difficult for an impostor setting up a false claim to simulate marks of this kind. The operation would require time, and an accurate imitation of the color and design, as well as of the part of the body selected. Members of the family would be able to say whether they were or were not such marks as those which had existed on their missing relative. There may be satisfactory proof that the missing person was tattooed, while an impostor may allege that he had not been tattooed. The fact, however, may be that at some former period of his life a man had undergone this operation, and to prevent a discovery of his identity, he had removed the marks by cautery or other means.

Colored cicatrices. Mode and date of production.—These marks arise from small punctured wounds made into the true skin with three or four sharp needles closely bound together. The needles are dipped in coloring matter at each time that the punctures are made. When the substance of the cutis is penetrated as it ought to be, in order to leave a permanent mark, there is in a few hours much swelling of the skin,

with general inflammation. The colors commonly employed in tattooing are charcoal (gunpowder), China ink, vermilion, and indigo. Other vegetable coloring matters of a fugitive kind are sometimes used. China ink and charcoal, although black, produce designs on a white skin which have a bluish tint. The coloring matter thus deposited mechanically in these minute punctured wounds, after the first attack of inflammation has passed off, remains permanently encysted in the substance of the cutis or true skin and in the cellular membrane below it. It has been there found after death.

According to M. Berchon, the local symptoms of irritation and inflammation last about a fortnight. At the end of the first month the lines of color appear wider than they will be ultimately. About the sixth week the cuticle begins to scale off, and at the end of about two months or a somewhat longer period, the skin acquires its normal condition. The designs in vermilion are at this early time much more intense than those in China ink. When the local symptoms have subsided, the tattoo-marks are fixed, and it is impossible to assign a date to them.

Durability of the marks. Alleged spontaneous disappearance.—In imperfect cases of tattooing, when soluble and fugitive colors are used, and the surface of the cutis only is penetrated, the marks may disappear or be removed by artificial means. Not so when the coloring matter is carried completely into the substance of the cutis or true skin. It there forms an intimate combination with the fibrous structure of the skin, and remains permanently fixed. M. Rayer has shown by the maceration of tattooed skin that the cuticle may be removed, and it is colorless as in ordinary skin. This, therefore, proves that the coloring matter is firmly imbedded in the cutis and cellular tissue below it. ("Ann. d'Hyg.," 1855, 1, p. 194.) A maceration of the skin in water for two months did not affect the color of the tattoo marks, and M. Tardieu found that no solvent could remove the coloring matter without at the same time destroying the texture of the skin (*Op. cit.*, p. 200). Tattoo-marks are not removed, because the coloring matter is insoluble and cannot permeate the roots of the vessels. Silver marks are equally indelible when deposited from taking inwardly the nitrate of silver. Finely divided substances, such as mercury, may penetrate; also finely divided charcoal, taken into the intestines, has been found in the mesenteric veins. ("Kirkes's Physiology," p. 276.) In 1874 I saw a case in Philip's ward, Guy's Hospital, which well illustrated the durability of these marks. The man, æt. 50, had been a sailor, and while in the China seas, from 1842 to 1847, he was tattooed at different times. There were numerous designs on both arms and the front of the chest, some of them artistically representing flowers and leaves, a flower-pot and human figures. There were only two colors, blue-black and red, the former done with China ink, the latter with vermilion. The operation had been performed by an English sailor. Three needles were used—these, dipped into the color, were introduced deeply into the skin sideways, or in a valvular form, and the ink mixed with water was then well rubbed over. The vermilion was rubbed in, in powder. Some blood flowed, and

after a few days the parts cicatrized, the scabs came away, and the man suffered no inconvenience.

The marks were deeply imbedded in the cutis: some were deeper in tint and blacker than others, this result depending on the strength of the China ink used. The colors had undergone no change up to 1874, although one of them at the back of the hand, representing a flower-vase with flowers, had been exposed to light and to frequent contact with water and other liquids, including naphtha, but it had made no difference in its appearance. The vermilion had also retained its color. It is a remarkable coincidence that on his left arm were the capital letters R. C. T., but these did not correspond to the initials of the name of the patient. The marks were unchanged after 32 years, and at the lowest estimate 26 years.

In most anatomical museums, preparations of tattooed skin may be seen. In Guy's Hospital Museum there are five. The designs have been produced with gunpowder and some small portions with vermilion. In one of them, which has been preserved in spirit for forty years, the marks on the skin of the leg represent an animal like a goat; they are of a bluish-black color. In the part from which the cuticle has been removed the color appears much more intense. There is nothing to indicate that this preparation has undergone the slightest change of color during its long maceration in spirit. This and the other preparations also show that no color is removed by removing the cuticle: on the contrary, the color becomes brighter and more intense by contrast with the white surface of the cutis. Another preparation of the skin of the arm represents in blue-black (carbon) and red (vermilion) the crucifixion, with the date—Nantes, 1808. In this also the cuticle has been removed in part, with the effect of bringing out the colors more strongly. Seventy years have passed since those marks were produced, but neither while living, nor in undergoing maceration in water and spirits after death, is there any appearance of change in the depth of color or in the outlines of the design. In a third, the skin was taken from the arm of a sailor who died in Guy's Hospital in 1857. The designs represent the arms of England, and Adam and Eve with the tree of life and the serpent. It has been noticed with regard to this preparation, that the red or vermilion color has become less marked during the years that it has been in the museum. Another preparation of the skin from over the scapula has simply a large letter D, the brand of a deserter. This was removed from a dead body in 1860. The fifth, of the date of about ten years, represents, in a very perfect manner, a ship in full sail with the figure of a woman. This portion of skin was taken from the body of a sailor. These facts show how durable the carbonaceous colors are when the substance has only penetrated the cutis. No amount of maceration appears in any way to affect or alter them.

A surveyor accidentally punctured the skin of the back of his hands with a sharp steel pen charged with China ink. A bluish-black spot was formed after the healing of the wound: this was quite visible and unchanged when I saw the hand after six years, and it would no doubt continue for life. A near relative of mine was tattooed with China ink on

the inside of the arm. The designs, which were of a bluish color, remained within my observation unchanged up to his death, *i. e.*, for the long period of twenty-eight years. It has been rather hastily assumed that in a certain percentage of cases, tattoo-marks spontaneously disappear in the course of time. Thus, Mr. Hutin examined 506 cases of tattooing. Relying upon the statements made by soldiers, sailors, convicts, and others, his conclusion was that in 47 the marks were completely obliterated after a period of from 28 to 60 years; in 117 the marks were partially obliterated after a period of from 10 to 64 years; but in 342 the marks were quite distinct after a space of from 4 to 65 years! With the exception of two cases of tattooing in vermilion which disappeared after 30 years, M. Tardieu found that the disappearance of tattoo-marks did not take place until after 30 to 40 years, and of the only two tattooings with China ink which were obliterated, one disappeared after 45 and the other only after 60 years.

These and similar facts show that in a few cases these marks may fade or become less visible, but this change requires a period of ten years at the least. The fading of the marks most probably arises, not from a removal of the coloring matter by the absorbents, but from the fact that in some cases the tattooing has been superficially performed on a thin skin. If the absorbents can remove from the tattoo-marks such insoluble colors as carbon and vermilion, it would scarcely require a period of from ten to twenty-eight years for their removal, and on this theory it would be impossible to explain why tattoo-marks remain permanent in any case. This subject has been fully considered by Dr. Horteloup. ("Ann. d'Hyg.," 1870, 2, p. 453, and 1872, 1, p. 423.) It is said that the vermilion color has been seen in substance in the neighboring absorbent glands, but it does not appear that mercury has ever been detected in these glands (Casper, "Gericht. Med.," vol. 1, p. 118), the crucial test of its presence!

The nature of the coloring material appears to have some influence on the durability of the tattoo-marks. Thus M. Hutin found that out of 78 persons who had been tattooed with vermilion alone, the tattoo-marks had disappeared in eleven, and that out of 104 tattooed with black pigment, such as carbon, China ink, etc., not one had become obliterated. This permanency of the black pigment has also been noticed by other observers.

The general conclusion from these observations is that tattoo-marks once properly made in the *cutis* are practically indelible, but that when the operation is imperfectly performed, the marks may, in the course of many years, become lighter and disappear. This is observed more commonly with red coloring matter than with the black or carbonaceous colors. As accurate information can seldom be obtained respecting the tattooing in early life, it may be inferred in a contested case in which the marks are proved to have disappeared, that the tattooing was imperfectly performed. This point, however, admits of refutation when it can be proved that the marks are still visible on the arm of another tattooed at the same time, by the same person, and with similar materials.

Removal of tattoo marks by art.—Many absurd statements have been made by convicts respecting the removal of tattoo-marks from their skins. The only methods by which such marks admit of removal are by excision of the cutis or the application of the actual cautery or escharotics to destroy the skin. In such cases cicatrices remain, which, under a proper examination, may lead to detection. A case occurred to M. Tardieu in which the fact of obliteration was the main question for solution. ("Ann. d'Hyg.," 1855, 1, 201.) A man named *Aubert* was charged with having committed a robbery in 1843. His defence was that he was at that date confined in a certain prison under the assumed name of *Solignon*. On searching the prison-register it was found that a man named *Solignon* was there confined at the date assigned, and the description of the prisoner showed that he was tattooed on both arms—on the left there were two hearts, a dog, and other emblems; on the right a man, a woman, a dog, and two hearts. On examining the prisoner *Aubert*, no marks of tattooing were seen upon his arms, although he affirmed that he had been tattooed by a friend in 1840, and again in 1846, with a blue vegetable ink, but that he had some months previously removed the marks by a chemical process. He also described the marks: those on the right arm represented the bust of a woman and the letters J. S., and on the left a tomb, with foliage, etc. In 1846 a hunting scene had been added, but this was the faintest of all. By close examination of the skin with a lens in a strong light, M. Tardieu was able to detect faint white marks like cicatrices representing the outline of a tomb, with two hearts; and the marks indicative of two letters were also detected on the skin of the other arm by the same means. By these observations the non-identity of the accused *Aubert* with the former prisoner *Solignon* was clearly proved. Both were tattooed, but the tattoo-designs were quite different, and under less skillful hands than those of M. Tardieu, *Aubert* might have escaped the punishment which he merited.

The prisoner *Aubert* communicated to M. Tardieu the plan which he had adopted for removing the tattoo-marks. He first applied an ointment of strong acetic acid. He then applied a weak solution of potash, and afterwards hydrochloric acid. The skin which had been removed by these caustics was gradually reproduced; but although the coloring material was removed, linear cicatrices were left in the skin in every part to which the tattooing needles had been applied. M. Tardieu subsequently tried this process on some tattoo-marks, and found that the coloring matter might be thus removed, but that traces indicative of the original designs were still left in the skin. Simple friction of the skin will sometimes suffice to bring out obliterated tattoo-marks. An escaped convict was on trial before a French court, and the question turned upon his identity with a prisoner known to have been tattooed. There was no appearance of colored marks upon his arm, and the question submitted to M. Leroy, who was consulted by the President of the Court, was—Whether the man had ever been tattooed? M. Leroy applied strong friction to the skin of the arm. This had the effect of bringing out white lines as cicatrices with a slight bluish tint. By this means the word "*Sophie*" was plainly legible in white marks on the reddened skin.

This fixed the identity of the convict, who thereupon was barely restrained from knocking down the witness. ("Ann. d'Hyg.," 1870, vol. 2, p. 460.)

As perfect tattooing cannot take place without deeply wounding the cutis and causing a cicatrix, we must not trust to the absence of color only when an opinion is required whether the person has or has not been tattooed. These observations equally apply to the destruction of the marks by fire. Dr. Horteloup examined the arm of a man, æt. 42, who at the age of 18 had been tattooed with China ink. At the age of 30 a bar of iron, at a white heat, accidentally dropped on the tattooed portion of his arm. Twelve years after this accident Dr. Horteloup found a white cicatrix on the arm which had obliterated part of the design (a ship). When the obliterated portion was minutely examined with a lens, faint white lines were seen which filled up and completed the figure of a ship. ("Ann. d'Hyg.," 1870, vol. 2, p. 459.) M. Bois de Loury met with an instance which proves that it is very difficult to eradicate the tattoo-marks without leaving distinct traces of them. In this case a man had a number of initials of names spread over the skin of his chest and arms, and in many parts he had obliterated the letters by a red hot iron applied to the skin—but in every instance there was a well-defined cicatrix, and it was still possible to make out traces of the letters. ("Ann. d'Hyg.," 1872, 1, 423.)

Tattoo-marks on the dead.—When we are required to examine a dead body for marks of tattooing, great caution is required if no colored marks are apparent on the skin. Putrefaction, unless very far advanced, does not interfere with their appearance. M. Tardieu states that in examining the partially decomposed body of a man who had been a carpenter, the tattoo-marks on his arm clearly represented the instruments of his trade. When the question is whether the marks have been on the arm and subsequently removed, there will be some difficulty. An examination of the skin with a lens in a strong light may show the presence of lines corresponding to cicatrices; but the evidence derivable from friction of the skin is here lost. Dr. Horteloup recommends the examination of the neighboring absorbent glands for the coloring matter; but if the marks are of many years' standing, coloring matter is not likely to be found in them. In this respect a case which occurred to the late Prof. Casper of Berlin is eminently instructive. In 1849 the body of a man, decapitated, was found in the neighborhood of Berlin. It was supposed to be that of one *Gottlieb Ebermann*, who was missing. It was stated that the body of Ebermann could be identified by marks of cupping on the wrists, an operation performed on him eight or nine years before his death, and also by tattoo-marks of a heart, and the letters G E on the left arm. On an examination of the body no marks of any kind could be perceived, and Ebermann's wife, who had been married to him two years, and his three sisters, affirmed that they had never seen any tattoo-marks on him. The body was exhumed after five months, but owing to putrefaction no further evidence could be obtained from it. A man of the name of *Schall* had been in the mean time charged with the murder, and the circumstantial evidence was so strong against him that nothing

more was required than to prove that the body found was that of Ebermann. Of two medical experts who were called to give evidence, one deposed that the marks of cupping could always be distinguished, and those of tattooing were indelible; the other stated that the marks of cupping might spontaneously disappear, but with regard to the tattooing he could give no opinion. As this medical evidence failed to establish the identity of the body, the opinion of Prof. Casper as assessor was required by the court.

In his report, taken from the observations made in a large asylum for aged and invalid soldiers, a class among whom tattoo-marks are common, he stated that out of thirty-six examples, in three the tattooing had become faint with time; in two, the marks were partially effaced; in four, they were completely obliterated; hence M. Casper came to the conclusion that the marks of tattooing may disappear. A witness came forward and declared, during the investigation, that at fifteen he had tattooed himself on the arm with cinnabar, and that the marks had become entirely effaced. The conclusion of the trial was, that Schall was condemned. (*"Med. Times and Gazette,"* Dec. 11, 1852; also, Casper's *"Ger. Medicin,"* 1, p. 116; and *"Vierteljahrsschrift,"* 1852, 1, p. 274, and 1853, 1, p. 338.)

The singular part of this case is, that there was a want of proof that the deceased had really been tattooed: for neither the wife who had cohabited with the deceased for two years, nor his three married sisters, had ever seen any tattoo-marks on his skin. Dr. Chereau, in *"L'Union Médicale,"* Nov. 16, 1852, justly observes, respecting Casper's report, that it is not one which should influence a judicial decision, for it is not stated at what age, with what substances, and in what manner, the marks were produced in the four instances where there was complete obliteration. Were the men to be trusted? How many years had really elapsed before the marks had become effaced? What was the nature of the coloring matter used? Was it mineral or vegetable, and was it carried deeply into the cutis or only disposed on the surface? These questions should have received satisfactory answers before comparisons were made, and important medical conclusion were based upon them. Casper's unqualified opinion that such marks, assuming them to have spontaneously disappeared, led to the conviction and execution of Schall. The accused confessed his crime before execution, but the position assumed by Casper on this occasion is certainly not a precedent to be followed by medical jurists. In all cases in which an opinion is required of a medical man—whether tattoo-marks have been effaced from the skin or not—there should be no doubt whatever touching their previous existence.

A question may arise in contested identity, whether any accidental or temporary marks made on the skin can be mistaken for tattooing? This does not seem at all probable. The color and the design might be imitated by water-color pigments, but this would be only superficial, *i. e.* on the cuticle, and they would be readily removed by water. No professional man could be deceived by such an attempt at imposture.

It may be suggested that marks of tattooing said to have been seen by witnesses on the skin of a missing person, were caused by the applica-

tion of colored chalk or pencil. Such an objection to evidence hardly needs serious refutation. Colored marks could only be produced by very soft chalk, and would never have the depth, intensity, or appearance of tattooing. They would be removed and obliterated by the slightest friction. The most superficial observer could not be deceived by them. Again, it may be alleged of a missing person, by one set of witnesses, that he was tattooed, and by another set that they had had casual opportunities of seeing his skin and did not observe any tattoo-marks. In such a case, the evidence given by near relatives, whose opportunities of observation are much more frequent, is more reliable than that of persons who could have had only an opportunity of seeing the bare skin on some rare occasions, and could have had no particular reason at the time for observing its condition. This, of course, becomes simply a question of credibility and accuracy of observation.

Medical responsibility.—The process of tattooing is not unattended with danger. Cases are recorded in which syphilis has been thus transmitted by inoculation. ("Ann. d'Hyg.," 1855, 1, p. 175.) M. Berchon has collected four cases in which the operation proved fatal by reason of the after-consequences. ("Ann. d'Hyg.," 1870, vol. 2, p. 464.) This author advises that the practice should be stopped by legislation. He holds that tattooing should be treated as unlawful wounding! As the operation is not usually performed by medical men, no responsibility can be incurred by them. The act is voluntary on the part of the person tattooed, and there is nothing in the results, at least in this country, to justify legal interference.

A medical man may be consulted about the removal of these marks, and when he has tried experiments on this subject he will be able to appreciate the view generally entertained of their indelibility, at least so far as the carbon-marks are concerned. A few years since I was consulted in the following case: By an accidental discharge of gunpowder a portion was blown into the face of a young man. After recovery from the first effects, a bluish-black tint was left on the lower part of the forehead, the nose, and the upper part of the cheeks and eyelids. He had consulted several physicians and surgeons, and under their advice had employed various local applications for the removal of the marks, but without result. I saw him a year after the accident. On examining the discolored parts with a magnifying glass, it was obvious that the small particles of carbon were deeply and firmly imbedded in the cutis. Local applications to promote absorption were tried, but it was quite evident that nothing but the destruction of the cutis would remove the marks. Blistering would have no effect, as this would only remove the cuticle.

Medico-legal questions connected with the presence or absence of tattoo-marks on the skin, have been hitherto confined to proof or disproof of the identity of persons charged with crime. Probably few cases in the present century have excited greater interest among the public or given rise to greater discussion than that which is known as the Tichborne case. (*Tichborne v. Lushington*, C. P. 1871-2, and *Reg. v. Castro or Tichborne*, August, 1873.) The question involved turned entirely upon personal identity. A man calling himself Sir Roger Tichborne claimed

certain estates. This led to a trial of ejectment in the Common Pleas, which extended over one hundred and three days, in which he was nonsuited, and subsequently committed for trial on numerous charges of perjury. After a trial for this offence of the unexampled duration of one hundred and eighty-eight days, the claimant was found guilty of perjury and sentenced to penal servitude.

It would be out of place in this work to enter into all the details disproving the claimant's identity with the real heir to the estates, namely, Roger Charles Tichborne. This person was lost at sea in April, 1854. No one who sailed in the same ship had ever been seen or heard of afterwards. At the time of his departure from England in 1852, the real Roger had upon the inside of his left forearm certain tattoo-marks of a blue color, representing a cross, a heart, and an anchor. These marks had been distinctly seen up to the time of his leaving England, over a period of six years, by his mother, his tutor, and a number of friends, male and female, to whom he had at intervals purposely shown them. Lord Bellew, a schoolfellow of Roger, deposed that in 1847-8 he saw the cross, heart, and anchor on Roger's arm, and that he himself tattooed the letters R C T in addition to these symbols. The letters were made with Indian ink, and were half an inch in length. On the same day that he tattooed Roger's arm, Roger tattooed his arm with an anchor. This was done at the same time and with the same materials. Twenty-five years had elapsed since they had thus tattooed each other, but the anchor was still there, and the witness showed his arm to the jury in confirmation of his statement.

It was further proved that as attempts had been made to bleed the real Roger in the arms, feet, and temple before he left England, there would be some *cicatrices* indicative of this fact. When a boy he had an issue in his arm for two years, and when this was removed and the part healed, it had left a large and deep cicatrix. These facts were deposed to by several credible witnesses. The depression in the arm left by this issue was seen by them as late as nine years after its removal. Such were the facts satisfactorily proved with regard to the real heir.

Twelve years after the wreck of the *Bella*, in which Roger Tichborne was lost, the defendant Castro, who was residing in Australia, first set up a claim to the estates, announcing that he was Roger, and had been saved from shipwreck. This, however, was proved to have been after some advertisements had appeared in the Australian papers, offering a reward for the discovery of any survivor of the *Bella*.

A large amount of evidence was received for and against the defendant's identity. It is only necessary to consider in this place the medical evidence derivable from *tattoo-marks* and *cicatrices*. There was no mark of tattooing about the person of the defendant, nor any appearance indicative of his having been tattooed. Dr. Lipscombe, his physician, had examined him, and found no tattoo-marks, and to add to the force of this evidence, the defendant himself denied that he had ever been tattooed. As to *cicatrices*, the evidence equally failed. The late Sir W. Fergusson, who was a witness for him, and other surgeons examined his arms, temple, and feet, but found no cicatrix such as would have followed bleeding. There were some scars on the feet near the ankles, but these had

not been produced by incisions for bleeding in the feet. There was no scar or depression in the arm where an issue had been placed in the real Roger.

Unless we are prepared to admit that a man can be tattooed and have no knowledge of the fact, and having been thus unconsciously tattooed that all the marks had disappeared before he saw them, it is impossible that this claimant could have been the Roger Charles Tichborne, the heir to the estates. The durability of the marks was clearly proved by Lord Bellew. So, again, with regard to cicatrices. There were none to render the story of the defendant even plausible, and taken together with the tattoo-marks, they were in flat contradiction to his assertion. Resting upon these medical facts alone, there was sufficient to overthrow his claim and to prove him to be an impostor; but there was an accumulation of other evidence, based upon the early history, education, travels, and habits of the lost heir, which clearly showed that this was a false claim. That this impostor should for so long a period have defied the law and deluded a large number of persons, is in itself surprising. It points, as a public writer suggests, to a deficiency of common sense, and the imperfect education of a large proportion of the English people.

Pending the Tichborne trial, a man named *Jean Luie* presented himself as a witness for the defendant, and swore that he was on board the *Bella* with the defendant, and had escaped with him from the wreck. It was, however, proved that he was a ticket-of-leave convict named Lungren, who had been repeatedly in gaol, and was recognized by several gaolers. Lungren, according to the gaol-books, had a deformity of the little finger of each hand, and certain moles were upon his back. All these were found on the pretended Jean Luie. He was committed and punished for thus endeavoring to defeat justice by flagrant perjury. *In re lupanari testes lupanares.*

CHAPTER XXXIII.

WOUNDS OF THE HEAD.—CONCUSSION.—HOW DISTINGUISHED FROM INTOXICATION.—EFFUSION OF BLOOD AS A RESULT OF VIOLENCE, DISEASE, OR MENTAL EXCITEMENT.—WOUNDS OF THE FACE.—DEFORMITY AS A CONSEQUENCE OF WOUNDS OF THE FACE.—INJURIES TO THE SPINE AND SPINAL MARROW.—FRACTURES OF THE VERTEBRÆ.

THE *danger* of wounds, and their *influence in causing death*, are the two principal points to which the attention of a medical jurist must be directed.

WOUNDS OF THE HEAD.

Incised wounds, affecting the scalp, unless of great extent, rarely produce any serious effects. When the wound is contused, or accompanied by much laceration of the skin, it is highly dangerous in consequence of the tendency which the inflammatory process has to assume an erysipela-

tous character. The results of these wounds are, however, such as to set all general rules of prognosis at defiance. Slight punctured wounds will sometimes terminate fatally in consequence of inflammation, followed by extensive suppuration; while, on the other hand, a man may recover from a lacerated wound by which the greater part of the skin may have been stripped from the bone. There are two sources of danger in *wounds of the scalp*: 1. The access of erysipelatous inflammation; 2. Inflammation of the tendinous structures, followed or not by a process of suppuration. Either of these secondary effects may be a consequence of slight or severe wounds, and prove fatal. Neither can be regarded as an unusual result of a severe wound of the scalp, but when one or the other follows a slight injury, there is reason to suspect that the patient may have been constitutionally predisposed to the attack. Bad treatment may likewise lead to a fatal result from a wound not serious in the first instance, but the question,—how far the responsibility of an aggressor would be affected by a circumstance of this nature, has been considered in another place (p. 275). Wounds of the head are dangerous in proportion as they affect the brain; and it is rare that a severe contused wound is unaccompanied by some injury to this organ. There is, however, a difficulty which a practitioner has here to contend with, namely, that it is scarcely possible to predict from *external* appearances, the degree of mischief which has been produced within. These injuries, as it is well-known, are capricious in their after-effects—the slightest contusions may be attended with fatal consequences, while fractures, accompanied by great depression of bone, and an absolute loss of substance of the brain, are sometimes followed by perfect recovery. Another difficulty in the way of forming a correct opinion consists in the fact that a person may recover from the first effects of an injury, but after some days or weeks he will suddenly die; and on examination of the body, the greater part of the brain will be found destroyed by suppuration, although no symptoms of mischief may have manifested themselves until within a few hours of death.

Concussion.—The common effect of a violent blow on the head is to produce concussion or effusion of blood, or both. Concussion is usually indicated by fainting, insensibility, or sudden death occurring immediately or soon after the application of external violence. In concussion the symptoms come on at once, and the patient sometimes dies without any tendency to reaction manifesting itself. In the most severe form, the person drops at the very moment when struck, and dies on the spot. (Chelius's "Surgery," vol. 1, p. 408.) In other cases, he may linger in a state of insensibility for several days or weeks, and then die. In concussion there is generally more or less vomiting. It is important to remember that neither compression nor physical injury to the brain is necessary to render concussion fatal. This may be entirely dependent on shock to the nervous system. After death, no particular morbid change may be discovered in the body, or there may be merely the mark of a slight bruise on the head. The state of insensibility observed in concussion may be only apparent; a slight degree of consciousness may be retained. A blow on the skull may cause death by leading to abscess

in the brain, although there may be no fracture or other physical injury. A case of this kind proving fatal in about a week is reported by Mr. Lloyd. ("Lancet," May, 1873, p. 697.)

Inflammation may follow the primary shock from concussion—suppuration may take place, and the patient die after the lapse of several weeks, or even months. It is necessary in a medico-legal point of view to notice that a person may move about and occupy himself, while apparently convalescent, for a week or ten days after recovery from the first shock, and then suddenly be seized with fatal symptoms, and die. This apparent recovery leads to the common supposition that death must have been produced by some intervening cause, and not by the original violence to the head, a point generally urged in the defence of such cases. When the inflammation that follows concussion is of a chronic character, the person may suffer from pain in the head and vomiting, and die after the lapse of weeks, months, or even years. Concussion may sometimes take place as a consequence of a violent fall on the feet, in which case the head receives a shock through the medium of the spinal column. The skull may be thereby extensively fractured at the base, and the brain may be even shattered by such a fall. This was the cause of death in the case of the *Duke of Orleans*, the son of Louis Philippe.

In *Allen v. The Chester Railway Company* (Court of Common Pleas, Feb. 1857), the plaintiff claimed damages for an injury caused by a railway collision. The evidence showed that the plaintiff received a blow on the head. There were no immediate effects; but in two days he suffered from lightness of the head and other symptoms, attributed by his medical attendant to *concussion* of the brain, as a result of the accident. Subsequently there were symptoms of injury to the spine. There was pain in the course of the spine, partial paralysis of the bladder, rectum, and legs, with loss of memory. The medical witnesses for the plaintiff attributed these symptoms to a blow received by him at the base of the skull. The defendants contended that if these were the results of concussion of the brain, they ought to have manifested themselves immediately on the occurrence of the accident; and this view was to some extent supported by the evidence of experienced surgeons. In substance, however, the medical evidence on the two sides was not conflicting. Concussion of the brain, as it is ordinarily known to surgeons, is generally attended with some *immediate* symptoms; but the witnesses for the defence properly admitted that "a concussion of the brain (and spine?), attended with apparently slight symptoms at first, might, under peculiar circumstances, be followed by serious symptoms." As no other cause could be assigned for the symptoms, this was practically admitting that the plaintiff had suffered from the injury, the degree being simply a question for the jury. They returned a verdict for the plaintiff.

Concussion distinguished from intoxication.—The symptoms under which a wounded person is laboring may be sometimes attributed to *intoxication*, and a medical witness may be asked what difference exists between this state and that of concussion. The history of the case will, in general, suffice to establish a distinction, but this cannot always be

obtained. It is commonly said that the odor of the breath will enable a surgeon to detect intoxication; but it is obvious that a man may meet with concussion after having drunk liquor insufficient to cause intoxication, or concussion may take place while he is intoxicated—a combination which frequently occurs. Under such circumstances we must wait for time to develop the real nature of the case. Concussion may be so slight as sometimes closely to resemble intoxication, and from the absence of all marks of violence to the head and the existence of a spirituous odor in the breath, the medical examiner might be easily deceived. If there be no perceptible odor in the breath, the presumption is that the symptoms are *not* due to intoxication. On the other hand, intoxication may be so great as to give rise to the apprehension of fatal consequences, and the coexistence of a mark of violence on the head might lead to error in the formation of an opinion. What is the line of conduct to be pursued on such occasions? The examiner should weigh all the circumstances, and if there be one cause for the symptoms more probable than another, he should adopt it:—if there be any doubt, this should be stated to the court. There is great reason to believe that this mistake is still frequently made, and that a person in a state of insensibility from violence or disease, has his death accelerated by confinement in a cell as a drunken person, when it subsequently transpires that he has not been drinking, and that he really required medical aid.

There is nothing in the state of the brain in a dead body, which will enable a practitioner to distinguish whether concussion or intoxication had existed and had been the cause of the symptoms. The vessels may be congested in both cases. The discovery of an alcoholic liquid in the stomach might lead to a presumption that deceased had been intoxicated, while marks of violence on the head might favor the view that he had suffered from concussion. When both conditions are found, the examination of the body cannot lead to a solution of the question. The answer must then depend on the special circumstances proved, and, if procurable, on the nature of the symptoms preceding death. It is to be feared that medical witnesses are not sufficiently careful, on these occasions, to determine whether there are signs of intoxication about an injured person. Subsequent proceedings may render this a material part of the inquiry.

The distinction of apoplexy from drunkenness involves greater difficulties. In these cases we have to deal with the true diagnosis of alcoholic or narcotic poisoning. Dr. Jackson has directed attention to this medical question in a case reported in the "*Med. Times and Gaz.*," 1871, 1, 360. Some instructive cases, in reference to this complication of wounds, have been published by M. Tardieu. (See "*Med. Gaz.*," vol. 44, p. 847.)

Extravasation or effusion of blood.—A blow on the head may destroy life by causing an effusion of blood either on the surface or in the substance of the brain. In pugilistic combats, when a person is thus struck, he commonly falls, and death may take place in a few minutes. On inspection, blood may be found effused either at the base or in the ventricles of the brain, and the question will present itself: Did the injury which caused death arise from a blow or a fall? A heavy blow on the

head may cause fatal effusion of blood, but on these occasions the effusion commonly arises from the violent concussion which the injured person sustains by the fall. A medical witness will, therefore, in general be compelled to admit that the fatal effusion might have taken place either from a blow or a fall. If the fall has resulted from accident and not from a blow, this will, of course, absolve the accused from responsibility for the fatal results. This subject has important applications in legal medicine, for this is one of the most common causes of death from injuries to the head, and there are generally many cases of this description tried at the Assizes. Effusion may occur from violence with or without fracture, and it may take place without being accompanied by any external marks of injury.

In case of injuries to the head proving fatal by *effusion* of blood on the brain, a person may recover from the first effects of the violence and apparently be going on well, when he will suddenly become worse and die. Effusion takes place slowly at first—it may be arrested by the effects of stupor from concussion, by a portion of the blood coagulating around the ruptured orifices of the vessels, or by some other mechanical impediment to its escape; but after a longer or shorter period, especially if the person be excited or disturbed, the bleeding will recur and destroy life by producing compression of the brain. How many hours or days are required in order that such an increased effusion should take place after an accident, it is impossible to say; but in severe cases, it is generally observed to follow the injury within a short time. Sir Astley Cooper has related the case of a gentleman who was thrown out of a chaise, and fell upon his head with such violence as to stun him in the first instance. After a short time he recovered his senses, and felt so much better that he entered the chaise again, and was driven to his father's house by a companion. He attempted to pass off the accident as of a trivial nature, but he soon began to feel heavy and drowsy, so that he was obliged to go to bed. His symptoms became more alarming, and he died in about an hour, as it afterwards appeared, from effusion of blood on the brain. When the brain has sustained laceration from violence, in addition to insensibility, convulsions are frequently observed.

Effusion of blood from disease or violence.—Blood may be found effused in various situations within the interior of the skull; and the cause of the effusion may be either disease or violence. The skill of a medical jurist is often required to determine which of these causes is the more probable, as where, for instance, a pugilist has died, after having received severe injuries to the head, and his adversary is tried on a charge of manslaughter. On these occasions it is often urged in the defence, that the bleeding might have arisen either from the diseased state of the vessels of the brain, or, if the evidence render it probable that the blow was the cause, that the effects of the blow were aggravated by a diseased condition of the vessels, or by the excitement into which the deceased was thrown, either from the effects of intoxication or passion. When the brain is not lacerated by violence, the blood is effused, either on the surface of the hemispheres, between the membranes, or at the base. When the effusion is caused by violence, the effused blood is not always found under the spot where the blow was inflicted, but occasion-

ally, by counter-stroke on the surface of the brain, directly opposite to it—a case which a medical witness has frequently been required to explain on trials, and which depends on the same cause as fracture by counter-stroke, *i. e.*, on a separation of parts (laceration of the brain, effusion of blood, or even fracture of the bones) at the point of the skull directly opposite to that which sustains the violence. Thus, fracture of the base of the skull is frequently the result of severe violence applied to the top of the head (vertex). Effusions of blood from a diseased state of the vessels more commonly take place in the substance of the brain, but they sometimes occur on the surface of the organ as a result of mere excitement or over-exertion of the muscular powers. A diseased condition of the vessels, and probably a softening of the substance of the brain, will, on these occasions, be apparent on inspection.

If the effusion depend on *disease*, the arteries around may be found diseased, or the brain itself may be found softened and disorganized. The state of the brain and its vessels should be closely examined in all cases of alleged violence, since hemorrhage may take place either from excitement or slight blows, whenever this diseased condition exists. It has occasionally happened, especially in old persons, that the person has dropped down dead without a blow being struck, and that death has been wrongly imputed to violence. Cerebral hemorrhage from disease rarely occurs in persons under forty years of age. Frequent intemperance and violent passion may, however, easily create a tendency to it in younger persons. As an effect of violence it may take place in persons of all ages, but when the marks of violence are slight, a witness must exercise great caution before he alleges that the effusion was produced by a blow, especially when it is found that the deceased was of intemperate habits.

Another condition besides intoxication and passion has been said to favor a rupture of vessels, and an effusion of blood on the brain—namely, a thickened state of the substance of the left ventricle of the heart. According to some pathologists, this morbid condition favors the occurrence of cerebral hemorrhage by the force with which the ventricle propels the blood to the brain. Unless the brain is softened and the vessels are diseased, it is, however, doubtful whether this condition of the heart would have much influence.

As a summary of these remarks, we may say that in effusions of blood from *violence*, the blood generally issues from a vessel which is plainly seen to be torn, as the middle artery of the brain or the lateral sinus. The effused blood is commonly found on the surface of the brain, and not in its substances, unless the organ is lacerated. When situate between the dura mater (outer membrane) and the skull, but especially when immediately below the seat of violence, or directly opposite to it by counter-stroke, this is strong evidence, *cæteris paribus*, that it has proceeded from a blow. When there is a fracture of the skull, the presumption of the extravasation being due to violence is great; because this is not only a sufficient, but an obvious cause, while the idea of its having proceeded from disease only is remote and speculative. When, besides these conditions, there is no remarkable congestion of the brain in other spots, when the substance of the brain is firm, and the vessels are to all appearance free from disease, we have the strongest reason to

believe that the effusion must have been due to violence, and to no other cause whatever.

The evidence given on some trials, when the main question has turned upon the *cause* of an effusion of blood on the brain, in the case of a person who has sustained violent injuries to the head, has rather tended to reflect disgrace on medical science. It has been made to appear from the mouth of the medical witness, either directly or by implication, that no sort of mechanical violence applied to the head of a man in a state of drunkenness or passion—of one whose cerebral vessels were probably diseased—or the substance of whose heart might be thickened—could have had any effect in producing a fatal extravasation found in the head after death! In spite of an individual having received a violent blow with a bludgeon, sufficient to have killed a stout and vigorous man, or of his having been thrown with considerable force with his head against a stone floor, an unqualified admission is often made, that excitement alone, or drunkenness alone, would account for the effusion without reference to the blow! In putting the most favorable construction upon these cases, when we have clear evidence of great violence having been used to the head, with the presence of the usual post-mortem appearances, our opinion should be that the excitement or drunkenness might have predisposed to, but was not the immediate cause of, the cerebral hemorrhage. There seems to be no good reason for assuming that apoplexy from natural causes always occurs by a peculiar coincidence, just at the time that the person receives a violent blow with a bludgeon on the head, or for giving to the assailant the benefit of this hypothetical explanation! A mere inspection of the body does not always lead to the discovery of the cause of an effusion on the brain. The violence producing an effusion of blood may have been slight, and unless attention is particularly directed to the subject, it may be overlooked. The condition of the effused blood should be accurately noticed, in order to determine whether it presents any marks indicative of its being recent or of old standing.

Spontaneous effusions or effusions from disease are not easily distinguished from those which are the result of violence to the head. Dr. Wilks has pointed out that in most instances of *severe* injury attended with effusion of blood, the structure of the brain is found bruised. In meningeal apoplexy (apoplexy of the membranes) the source of the blood is a vein of the pia mater or inner membrane, and sometimes a large arterial trunk. The difficulty chiefly arises in those cases in which effusion is found after slight violence, and there is, at the same time, disease of the bloodvessels of the brain. Dr. Wilks gives the results of several inspections in which effusion was owing to disease—to violence, and to a mixed condition. (See “Guy’s Hospital Reports,” 1859, p. 120.)

Effusion of blood from excitement.—When engaged in the investigation of these cases, it is always a fair matter of inquiry whether the *violence*, upon the evidence, was not of itself sufficiently great to account for the effusion without the supposition of coexisting disease or excitement. Admitting that the rupture of a bloodvessel, and the extensive effusion of blood on the brain, may take place from simple *excitement* and passion, yet this is an event comparatively rare, at least in the young and healthy, while nothing is more common than that these results should

follow violent injuries to the head, whatever the age or condition of the person. A medical witness should remember that on these occasions, if he is unable to say positively whether the effusion was due to the excitement or the blows, he will satisfy the court if he only states clearly that which is, in his own mind, the more probable cause of death; and by weighing all the circumstances of the case beforehand, he will rarely fail to find that one cause was more probable than the other. Thus, if a man, excited by passion and intoxication, is struck on the head, and the blow is slight—such as an unaffected person would probably have sustained without injury—yet in this case insensibility and death follow, and, on examination, a quantity of blood is found effused in the substance of the brain, can it be a matter of doubt with the practitioner that the effusion was chiefly due to the excitement under which the deceased was laboring? To take a converse instance—a man engaged in a personal conflict with another, is struck most violently on the head, or falls with great force on this part of the body; on an inspection it is found that death has arisen from effusion of blood on the surface of the brain, and it would be no unexpected consequence of the violence inflicted, that a similar appearance should be met with in an individual calm and unexcited: can the practitioner hesitate to say, under these circumstances, that the blow would satisfactorily account for the effusion, without reference to any coexisting causes of excitement? These may be allowed to have their influence, in giving an increased tendency to cerebral hemorrhage, or in aggravating the consequences of the blow, but no further.

In these criminal investigations, when a witness is examined in chief, he asserts, perhaps, that the effusion of blood was owing to a blow inflicted on the head. The counsel who cross-examines him, then puts the leading question, whether vessels may not be ruptured by excitement; he answers, without any qualification, in the affirmative, and thus produces an impression on the minds of the jury that excitement may have caused the rupture of the vessel in the particular case on which he is being examined. This is, of course, the sort of answer which a prisoner's counsel wishes to extract from a witness; and the effect produced by it on the court is not always removed, even by a careful re-examination. The counsel for the defence is well aware that in a case of this description, his only chance of obtaining an acquittal is to throw a degree of doubt on the medical evidence, and to render it probable to a jury that the death of the deceased person was due to some other cause than the blow inflicted by the prisoner. As leading questions are allowed to be put to any extent in a cross-examination, the answer in the monosyllable "yes" or "no," generally carries with it much more than a medical witness intends. It may be very proper that a skilful barrister should exercise his talents in this way, but a medical witness has to remember that he is sworn to state the *whole* truth. A qualified answer should be given to what is really a general question; and, supposing his opinion to be already formed on the subject on which his evidence is required, he should not, unless it be strictly consistent with his own views, allow his answer to a *general* question to be made applicable to a *particular* case. If then asked, in cross-examination, whether vessels might not be rup-

tured, and blood extravasated by mere *excitement*, he should answer that such an effect might undoubtedly follow ; but that it was his opinion—and I am here supposing that his opinion has been founded upon a deliberate examination of all the *medical* facts—that excitement was *not* the cause of rupture and extravasation in the case in question. A witness has, it appears to me, a right to insist that his evidence shall pass to the jury without having any designed ambiguity attached to it. It may be said that the remedy for an evil of this kind is the re-examination of the witness ; but I am satisfied from the reports of many cases before me, that the point is overlooked. Besides, one cannot understand why a piece of sophistry and equivocation is to be left to a chance exposure ; the case would then rest, not upon sound medical evidence, but upon the relative degree of ingenuity and ability displayed by the counsel for the prosecution and defence.

Date of effusions.—Recent effusions of blood are recognized by their red color, and the consistency and appearance of the clot or coagulum. After some days the clots acquire a chocolate or brown color, and this passes gradually into an ochreous tint, which may be met with in from twelve to twenty-five days after the violence. (Cases by Dr. Wilks, "Guy's Hosp. Rep.," 1859, 5, 122.) Coagula of effused blood also undergo changes in structure and consistency ; when old, they are firmer, and there is much lymph, which is sometimes disposed in membranous layers of a fibrous structure, and these are adherent to the dura mater and the brain. The surface of this organ sometimes presents a mark indicative of pressure. When a medical man is required to give an opinion of the *date* of an effusion found on the brain, great caution is required. He may not be able to fix the precise date, but it may be in his power to say whether the blood has been effused for a few days, or for weeks, or for months.

When a blow on the head is of a heavy bruising kind, the whole substance of the skull may be fractured without a division of the skin. There is one remarkable circumstance connected with fractures accompanied by depression of bone, which here requires to be mentioned—namely, that the person has been sensible so long as the foreign substance which produced the fracture and depression remained wedged in the brain, and that insensibility and other fatal symptoms began to manifest themselves only after its removal. This being admitted, it may be urged in defence, that death was really caused by medical interference. But it is a sufficient answer to state, that the wounded person must have died from inflammation of the brain if the foreign body had been allowed to remain ; and that it is consistent with the soundest principles of practice to remove all such foreign substances without delay. In fractures of the skull with depression, it may become a question whether the surgeon raised the depressed portion of bone as soon as he ought to have done.

In the description of injuries of the head, it is impossible to avoid the use of terms with which members of the legal profession are not likely to be acquainted. In giving evidence upon the situation of wounds, of the effusion of blood, and the effects of fractures, medical witnesses are often compelled to make use of anatomical terms, and are not always

successful in explaining them. With the view of removing this difficulty, and supplying, to some extent, the means of following the evidence of a witness in his description of injuries to the head and its contents, an engraving, representing the relative position of the membranes of the brain, is annexed.

Fig. 60.

The skull with its outer and inner table, and the three coverings of the brain (membranes), seen in section.

Fig. 60 represents a section of the bones of the skull, with the three membranes which cover the brain. (a) Section of the skull-bones, with the outer and inner tables, and the intermediate cellular structure or diploe, indicated by the dark shading; the scalp, or skin of the skull, which covers the outer table, is not represented. (b) The dura

mater, or outer membrane of the brain; it is thick and fibrous, closely adherent to the inside of the inner table of the skull, but smooth on the side towards the brain. (c) The tunica arachnoides, so named from its delicate web-like structure, smooth towards the dura mater, but closely covering the pia mater beneath. (d) The pia mater—the membrane which immediately invests the substance of the brain and dips into all the convolutions. It contains the bloodvessels which nourish the hemispheres of the brain. These membranes are, for distinctness, represented as being separated from each other, but they are naturally in close proximity, and the rough side of the dura mater is closely adherent to the inside of the skull (calvarium). The ordinary seats of the effusion of blood from violence, are between the dura mater and inner table of the skull, and between the pia mater and the surface, or in the substance of the brain.

In reference to persons found dead with severe injuries to the head, attended with fracture and effusion of blood on the brain, a medical man may be required to say whether such an amount of violence is or is not consistent with the retention of muscular exertion and power of locomotion by the deceased. For instance, a man may fall from a height, and produce a severe compound fracture of the skull. He may, nevertheless, be able to rise and walk some distance before he falls dead. Under these circumstances, there might be a strong disposition to assert that the deceased must have been murdered—the injuries being such that they could not have been produced by himself, there being at the same time no weapon near, and no elevated spot from which he could have fallen. The discovery, after death, of severe injury to the head, with great effusion of blood on the brain, must not, however, lead a surgeon to suppose that the person who sustained the violence had been *immediately* incapacitated. There are various cases recorded which show that a power to move has been retained under conditions which might be supposed to render a person incapable of moving from the spot. Full allowance must be made on these occasions for the possible exercise of locomotion by the deceased. Although a large quantity of blood may be found after death pressing on the substance of the brain, it does not follow that this effusion and pressure were the immediate results of the violence. (See case, p. 272.)

The importance of these observations will be further seen by the following medico-legal case, reported by Dr. Wallace. A man was found dead in a stable, with a severe fracture of the temporal bone, which had caused a rupture of the middle artery of the brain. A companion was accused of having murdered him, but he alleged that the deceased had fallen from his horse the day before, and had thus met with the accident. It appeared, however, that after the fall, the deceased had gone into a public-house before he returned to the stables, and had remained there some time drinking. The question respecting the guilt of the accused party rested upon the fact whether, after such an extensive fracture of the skull, with extravasation of blood, it was possible for a man to do what the prisoner had represented the deceased to have done. Dr. Wallace gave, very properly, a qualified opinion; he said it was improbable, but not impossible that, after receiving such an injury, the deceased could have walked into and drunk at a public-house. The extravasation was here the immediate cause of death, and probably this did not take place to the full extent, except as a consequence of the excitement from drinking.

Wounds of the brain.—Wounds of the brain sometimes prove instantaneously mortal, even when slight, while in other cases recoveries take place from contused or punctured wounds of this organ, contrary to all expectation. When a person survives the first effects of the injury, there are two sources of danger which await him: 1. The production of fungus from the exposed portion of the brain; and, 2. inflammation and its consequences. The process of inflammation, it must be remembered, is very slowly established in this organ; it may not manifest itself until from three to ten weeks after the injury. In one remarkable case, where a child was accidentally shot through the brain, the ball having traversed both hemispheres, no symptoms of cerebral inflammation manifested themselves for twenty-six days. The child died on the twenty-ninth day. ("Med. Gaz.," vol. 39, p. 41.)

Fatal wounds of the brain may be produced by pointed weapons being passed through the eye or the nose. In the former case, the thin orbital plate of the frontal bone is penetrated, and the brain which lies upon it is directly wounded. When the nose is the subject of a penetrating wound, the cribriform plate of the ethmoid bone is pierced, and the anterior lobes of the brain are wounded. In January, 1880, a man was convicted of the murder of his wife by forcing a tobacco-pipe up her nostrils, and thus fatally wounding the brain.

[Many instances have been reported where portions of the brain have been destroyed as the result of accident, and yet life has been preserved. A remarkable case is recorded in the "Amer. Journ. Med. Sci.," July, 1850, by Prof. Bigelow, of Boston. A man was preparing a charge of powder for blasting rocks; a premature explosion ensued, which resulted in projecting a bar of iron weighing thirteen and a quarter pounds, three feet seven inches in length, and one and a quarter inches in diameter, directly through his head and high into the air. The man was slightly convulsed at first, but he soon recovered his senses, riding some distance to his home, and giving a clear account of his accident. His subsequent recovery was complete, with the exception of the loss of one eye.

Wounds of the base of the brain and of the cerebellum are the most fatal.—R.]

Wounds of the face.—When wounds of the face are of any extent they are usually followed by great deformity; and when they penetrate the cavities in which the organs of the senses are situated, they often prove fatal, either by involving the brain and its membranes, or by giving rise to inflammation of this organ. Wounds of the *eyebrows* are not of so simple a nature as might at first sight be supposed. Besides being attended with deformity when they heal, they are liable to cause, during the process of healing, serious disorders of the neighboring parts. Amaurosis and neuralgia are recorded among the secondary and not unusual consequences of such wounds, when the supra-orbital nerve has become implicated. Under certain conditions of the body, there may be inflammation of the parts within the orbit, extending by contiguity to the membranes of the brain, and proving fatal by leading to the formation of matter within that organ. Amaurosis in the right eye has been known to occur from a contused wound, not of a violent nature, on the right eyebrow. Wounds apparently confined to the external parts of the face frequently conceal deep-seated mischief. A sharp instrument penetrating the eyelid, and passing upwards with any force, will produce fracture of the orbital plate of the frontal which is known to be extremely thin, and even injure the brain beyond.

Deformity as a consequence of wounds of the face.—Wounds of the face when at all extensive, are always followed, in healing, by greater or less deformity. A medical witness may, perhaps, find these questions put to him in relation to them: Is the wound likely to be attended with deformity? Could such a wound of the face heal without deformity?—or, Could the deformity, if it exist, have been produced by any other cause than the wound? These questions are of some importance. A person may allege that he was severely wounded in the face when the medical witness, on examination, may find no trace of such a wound as that described. Again, a person may seek damages from another in a civil action, by alleging that a particular deformity was produced by a wound, when the medical witness may be able to trace its origin to disease, or to some accidental cause.

INJURIES TO THE SPINE.

Injuries to the spine and spinal marrow seldom require medico-legal investigation; but this organ is liable to *concussion* from blows, to compression from fracture of the vertebræ, or the effusion of blood with all the secondary consequences attending such accidents. Concussion of the spinal marrow commonly produces paralysis, affecting the bladder, rectum, or lower limbs. These symptoms may not appear at once, but come on after some hours or days. After death no traces of mechanical injury may be discovered. Blows on the spine, unattended with fracture or dislocation, may, according to the observation of Sir B. Brodie, be followed by inflammation and softening of the spinal marrow. A slight injury has thus been known to cause death, by giving rise to inflammation

of the spinal marrow. This organ is also liable to compression from slight causes, and death may occur from paralysis of the nerves of respiration.

Fractures of the vertebræ.—These fractures are generally attended with displacement, and thus produce compression of the spinal marrow. They are the more rapidly fatal in proportion as the injury is high up in the vertebral column. The whole of the body becomes paralyzed below the seat of injury, as a result of the compression of the spinal marrow. If the seat of compression is above the fourth cervical vertebra, death is commonly immediate: asphyxia then results from paralysis of the nerves which supply the diaphragm, and which are necessary to respiration. In falls on the summit of the head from a height, it sometimes happens not only that the skull is extensively fractured, but that the dentiform process of the second vertebra is broken off, owing to the head being doubled under the body. This injury to the second vertebra may be the cause of death. From a case related by the late Mr. Phillips, it would appear that this accident is not always attended with fatal compression of the spinal marrow. (“Ed. M. and S. J.,” Jan. 1838.) In one instance the person survived fifteen months (ib. Oct. 1845, p. 527); and in another, in which the fracture was caused by the patient turning in bed while his head was pressed on the pillow, death did not take place for *sixteen* months. (Copland, “Dict. Pr. Med.,” Paralysis.) On several criminal trials, this injury was proved to have been the cause of death: and in a case tried at Glasgow (the *King* against *Reid*, 1835), it became a material question, how far such a fracture might result from disease. It may happen that caries of the bone, or disease of the transverse ligament, will cause a separation of the dentiform process from the second cervical vertebra. The state of the bone in these alleged fatal accidents should, therefore, be closely examined. [See Sir A. Cooper’s case of spontaneous luxation of the second cervical vertebra, from caries of the odontoid process. (Cooper on Dislocations and Fractures, p. 463.)—R.] A slight cause may sometimes produce severe and fatal injury to the neck. A lunatic in a private asylum suddenly threw her head back, in order to avoid taking some food that was offered to her, and she fell dead, evidently from the compression produced by a sudden displacement of the dentiform process of the second vertebra. A woman died suddenly a month after her confinement: she had been suckling her child at one o’clock in the morning, and at four she was found dead. The viscera of the abdomen, chest, and head were carefully examined, without the discovery of any morbid appearance to account for her death—when, as the brain was being returned into the skull, one of the inspectors noticed a projection at the foramen magnum. On further examination, the dentiform process of the second vertebra was found to have been displaced, and this had so injured the spinal marrow as to destroy life. (“Med. Gaz.,” vol. 3, p. 582.) It is not stated whether the bone was in a healthy or diseased condition. In fractures of the vertebræ, a person is generally so disabled, whatever may be the situation of the fracture, that he cannot walk or exert himself.

Injuries to the spine and its contents are generally the result of falls or blows, either on the head or the lower part of the column. The secondary consequences of these injuries are sometimes so insidious as to

disarm suspicion, and death may take place quite unexpectedly some weeks after the accident. Spicula of bone, separated by fractures, may remain adherent for some time; and, by a sudden turn of the head, be forced off, and destroy life by penetrating the spinal marrow, at a long period after the infliction of the injury. This has been known to happen in fractures involving the margin of the foramen magnum, and in such cases death is immediate. The *spinal marrow* has been in some instances wounded in its upper part by sharp-pointed instruments introduced between the vertebrae. Death is an instantaneous result when the wound is above the third cervical vertebra:—there is no part of the spine where a weapon can so easily penetrate as this, especially if the neck be slightly bent forward. The external wound thus made may be very small, and if produced with any obliquity by drawing aside the skin, it might be easily overlooked, or it might be set down as superficial.

CHAPTER XXXIV.

WOUNDS OF THE CHEST.—WOUNDS AND RUPTURES OF THE LUNGS AND HEART.—WOUNDS OF LARGE BLOODVESSELS.—WOUNDS AND RUPTURES OF THE DIAPHRAGM.—DIRECTION OF WOUNDS OF THE CHEST.—WOUNDS OF THE ABDOMEN.—DEATH FROM BLOWS ON THE CAVITY.—RUPTURES OF THE LIVER, GALL-BLADDER, SPLEEN, KIDNEYS, INTESTINES, STOMACH, AND URINARY BLADDER.—WOUNDS OF THE GENITAL ORGANS.

Wounds of the chest.—Wounds of the chest have been divided into those which are confined to the parietes or walls and those which penetrate the cavity. Incised or punctured wounds of the parietes of the chest are rarely followed by dangerous consequences. The bleeding is not considerable, and is generally arrested without much difficulty. They heal either by adhesion or suppuration, and unless their effects are aggravated by incidental circumstances, the person recovers. Contusions or contused wounds of the chest are, however, far more dangerous, and the danger is always in a ratio to the degree of violence used. Such injuries, when severe, are ordinarily accompanied by fractures of the ribs or sternum,—by a rupture of the viscera within the cavity, including the diaphragm,—by profuse bleeding,—or, as an after-effect, by inflammation of the lungs, with or without suppuration. Fractures of the ribs are dangerous for several reasons: the bones may be splintered and driven inwards, thereby wounding the lungs and causing hemorrhage, or leading to inflammation of the pleura or lungs. In fractures of the upper ribs, the prognosis is less favorable than in those of the lower, because commonly a much greater degree of violence is required to produce the fracture. A simple fracture of the sternum or chest-bone without displacement of the bone, is rarely attended with danger, unless the concussion has at the same time produced mischief internally, which will be known by the symptoms. When, however, the bone is depressed as

well as fractured, the viscera behind may be mortally injured. In a case of depressed fracture of the sternum, recorded by M. Sanson, the person died after the lapse of thirteen days; and on inspection, it was found that the fractured portion of bone had produced a transverse wound of the heart about an inch in length. The cavities of the organ had not been penetrated, but the piece of bone was exactly adapted to the depression produced by it on the parietes. (Devergie, "Mém. Lég." vol. 2, p. 243.) A witness will frequently be required to take into consideration the effects of contusions on the thorax, with or without fracture, in cases of death from pugilistic combats, which formerly gave rise to numerous trials on charges of manslaughter. Wounds penetrating into the cavity of the chest are generally dangerous, even when slight, in consequence of the numerous accidents with which they are liable to be complicated. In these wounds, the lungs are most commonly injured; but, according to the direction of the weapon, the heart, or the great vessels connected with it, as well as the œsophagus (gullet) or thoracic duct, may share in the mischief.

Wounds of the lungs.—The immediate cause of danger from wounds of these organs is the consequent hemorrhage, which is profuse in proportion to the depth of the wound and the size of the vessels wounded. Should the weapon divide any of the trunks of the pulmonary veins, the individual may speedily sink. The degree of hemorrhage cannot be determined by the quantity of blood which escapes from the wound; for it may flow internally, and collect within the cavity of the pleura, impeding respiration. This is especially to be apprehended when the external orifice of the wound is small and oblique, and one of the intercostal arteries has been touched by the weapon. A wound of the lung is generally known, among other symptoms, by the frothiness and florid color of the blood which issues from the orifice, as well as by the expectoration of blood. The lungs may sustain serious injury from a blow or fall, and yet there may be no external marks of violence or symptoms indicative of danger for some hours. During the convalescence of a person who has survived the first effects of a penetrating wound of the chest, the surgeon should observe whether death, when it occurs, may not have been caused either by imprudence on the part of the patient, or by abuse of regimen or other misconduct; for circumstances of this nature may be occasionally treated as mitigatory on the trial of an assailant. It is properly recommended that, in all cases where a person is progressing to recovery, a relaxation of the antiphlogistic regimen should be made with great circumspection. Too much nourishment, too frequent talking, or any exertion, are circumstances that may cause a renewal of the bleeding and extravasation.

Wounds of the heart.—Wounds of the heart are among the most fatal of penetrating wounds of the chest. It was formerly considered that all wounds of this organ were necessarily and *instantly* mortal. Undoubtedly, when either of the cavities is laid open to a large extent, the bleeding is so profuse on the withdrawal of the weapon, that death must be immediate. But when the wound is small, and penetrates into the cavities of the heart obliquely, life may be prolonged for a considerable period; and cases are on record in which it is probable that such wounds

would have healed, and the patients have finally recovered, but for the supervention of other diseases which destroy life.

[Numerous examples of wounds of the heart not directly fatal are cited by Beck (ii. 329-332) and by Stillé ("Wh. and Stillé," 2d ed., p. 580). We know of at least three others, occurring in Philadelphia, not noted in these works, in which the victim was proved to have walked several steps after having been wounded in the heart. See "Proc. of Path. Soc. of Phila.," in "N. A. Med.-Chir. Rev.," March, 1859, p. 299; also "New York Med. Times," April, 1855, for the case of Poole, referred to above from Dr. Darling; and in the same journal (May, 1855), "Statistical Observations on Wounds of the Heart, and on their relations to Forensic Med.," with a table of forty-two recorded cases, by Dr. Purple; also "Am. Journ. Med. Sciences," July, 1861, p. 293, for a case of bullet in the wall of the heart for twenty years. See, further, a paper "On Wounds of the Heart," by Dr. Jno. Redman Coxe, "Am. Journ. Med. Sci.," Aug. 1829, 307; and "Archiv. Génér. de Méd.," Sept. 1839, for a valuable paper "On Penetrating Wounds of the Heart," by M. Jobert De Lamballe.—H.]

It was the opinion of Dupuytren, that these injuries were not necessarily fatal, although I believe, with one exception, there is no case on record in which a person has recovered from a penetrating wound of the cavities of the heart. ("Ed. M. and S. J.," Oct. 1844, 557; also "Ann. d'Hyg.," 1846, t. 1, p. 212.) There are few, probably, who will be inclined to consider them curable; a remote possibility of simple wounds healing, and of the patient recovering, may be admitted, but until some clear instances of recovery from penetrating wounds of the cavities are reported, the majority of practitioners will continue to look upon them as fatal. From a series of cases collected by MM. Ollivier and Nanson, it appears that out of twenty-nine instances of penetrating wounds of the heart, only two proved fatal within forty-eight hours. In the others death took place at the varying periods of from four to twenty-eight days after the infliction of the wound. (Devergie, "Méd. Lég.," vol. 2, p. 253.) These differences in the time at which death occurs as well as the fact that wounds of the heart do not instantly destroy life, have been ascribed to the peculiar disposition of the muscular fibres of the organ, and to the manner in which they are penetrated by a weapon. It appears from the observations of M. Ollivier and others, that the right cavities of the heart are more frequently wounded than the left, and of these the right ventricle is most commonly the seat of injury. Out of sixty-four cases of wounds of this organ, twenty-nine were situated in the right ventricle, twelve in the left ventricle, nine in the two ventricles, three in the right auricle, and one in the left auricle. These differences are readily accounted for by the relative situation of the cavities. It appears also that wounds of the right ventricle are not only the most frequent, but of all others they are the most rapidly fatal. It is considered that the suddenness of death in severe wounds of the cavities of this organ is to be ascribed not merely to the loss of blood, but to the degree of compression which the heart experiences from that which escapes into the bag of the pericardium. In reference to the direction of penetrating wounds of the chest, it may be proper to state that the

base of the heart corresponds to the upper margin of the third rib on the left side ; and the apex to the lower margin of the fifth rib on the same side.

A penetrating wound of the heart was formerly considered to be instantaneously mortal, and the usual medical opinion at coroners' inquests was, that a person so wounded must have dropped down dead on the spot. More accurate observations have, however, shown that this is an erroneous, and in medico-legal practice, a highly dangerous doctrine. The *Duc de Berri*, who was murdered in Paris in 1820, survived eight hours after having received a wound of the left ventricle. Other and more remarkable instances of surviving have been recorded ; and it may be stated, that, although, in a surgical view, a question of this kind is of little importance, the case is very different in legal medicine. Upon it may depend the decision of questions relative to suicide, murder, or justifiable homicide. Mr. Watson met with a case in which a man who had been stabbed in the right ventricle ran *eighteen yards* after having received the wound. He then fell, but was not again able to rise ; he died in six hours. On dissection, it was found that a punctured wound had extended into the right ventricle in an obliquely transverse direction, dividing in its course the coronary artery. The pericardium was nearly filled with blood. When the cavities of the heart, especially the auricles, are extensively laid open, death is likely to be an immediate result ; but persons who have sustained wounds of this organ have frequently lived sufficiently long to exercise a power of volition and locomotion. In reference to penetrating wounds (stabs) little or no blood probably escapes from the heart in the first instance, but it may afterwards ooze gently, or suddenly burst out in fatal quantity. It must not, therefore, be supposed, when a person is found dead with a wound of the heart, attended with abundant hemorrhage, either that the flow of blood took place in an instant, or that the person died immediately and was utterly incapable of exercising any voluntary power. (See case by M. M. Masbrenier "Ann. d'Hyg.," 1879, 1, 257.)

Minute wounds of the chest, in the region of the heart, are sometimes made with the intention of destroying the lives of infants or children. In January, 1877, a woman was committed for trial at the Central Criminal Court under the following circumstances : She was charged with endangering the life of her infant, three months old, by thrusting a needle into its side between two ribs and near the heart. A surgeon was called to the child, and he extracted a long needle from the chest. In his opinion it could not have come there by any accident, and force must have been used to push it in. This woman failed in her attempt at murder by her ignorance of the situation of the heart. Strange as it may appear, a fatal wound of this organ by a needle may be the result of accident. The following case, communicated to me by Mr. May, of Newcastle-upon-Tyne, occurred under his observation in November, 1876. A mother was clasping to her bosom her child, two years of age, forgetting that she had just placed in her dress a needle, two inches long, with which she had been sewing some cotton article. The child screamed : she observed part of a needle with thread fall to the ground, and on removing the child's clothes, there was a red spot near the nipple, but no

trace of blood. Mr. May could find no trace of the broken needle, but considered about an inch and a half had been broken off and was imbedded in the substance of the heart. There is no doubt that this accidental wound was the cause of death.

The heart is liable to be *ruptured* either from disease or accident. In the latter case, the organ generally gives way towards the base, and through one of its cavities on the right side. Dr. Hope asserts that in ruptures from natural causes, it is the left side of the heart, and particularly the left ventricle, in which a rupture is most frequently found. The symptoms are sudden pain, collapse, cramps, cold extremities, and rapid death. According to the circumstances under which they occur, cases of rupture from disease may excite a suspicion of death from violence. Sometimes the substance of the heart may be found to have undergone fatty degeneration. As a medico-legal subject, it is worthy of note that when this alarming accident proceeds from blows or falls, it is not always accompanied by marks of external violence—or any fracture or other visible injury to the exterior of the chest. A girl, æt. 5, was knocked down and run over by a cart. When brought to the hospital she was quite dead, and there was no mark of injury upon any part of the body. On inspection, the pericardium was found to be full of blood, which had issued from a transverse rent across the apex of the heart. Both ventricles were laid open; the muscular substance was torn to a greater extent than the pericardium. The ribs were not fractured. The *natural* causes of rupture of the heart are violent mental emotions, such as anger, fright, terror, paroxysms of passion, sudden or excessive muscular efforts, or violent physical exertions in constrained positions. The heart, like any other muscle, may also give way from its own powerful contraction. When the heart is in a diseased condition, any slight causes of excitement are sufficient to produce rupture and sudden death. The mere exercise of walking rapidly or running, may thus give rise to fatal consequences, but death may take place quite suddenly while the person is at rest. A man, æt. 36, who had had no previous symptoms of illness, died suddenly during the night. On inspection, a rent, half an inch in length, was found in the right ventricle of his heart. The walls of the ventricle were soft and thin. There was a large effusion of blood, which accounted for death. ("Lancet," 1872, vol. 2, p. 41.) Another case of sudden death from rupture of the left ventricle is recorded in the same journal (1872, vol. 2, p. 524). In both cases sickness was an early symptom.

Wounds of arteries and veins.—Wounds of the large arterial and venous trunks around the heart must be considered as mortal: death is generally instantaneous from the sudden and profuse bleeding which attends them. With regard to these fatal effusions of blood within the chest, as well as in the other great cavities, it may be proper to mention that, from whatever vessel or vessels the blood may have issued, it is not commonly found coagulated to any extent. The greater part of it generally preserves the liquid state, and it is rare that so much as one-half of the quantity effused, is met with in the form of coagulum. These effusions of blood in the chest may be sometimes traced to wounds of the intercostal and the internal mammary arteries, or of the vena azygos.

Wounds of the *carotid arteries* have been considered elsewhere in reference to wounds of the throat (p. 279). Questions relative to the power of locomotion perhaps more frequently occur with respect to wounds of the bloodvessels of the neck than of the heart—suicide and murder being more commonly perpetrated by the infliction of such wounds. Wounds of the carotid arteries are often pronounced *instantaneously* mortal. A witness may deliberately state that the person could not possibly have survived an instant. This is a very hazardous opinion, for it occasionally comes out, on inquiry, that if such a wound had been *instantaneously* mortal, then, in defiance of rational probability, or of the strongest presumptive evidence to the contrary, the deceased must have been murdered! A medical opinion of this kind has not only been refuted by circumstances, but by the evidence of eye-witnesses. The witness is then compelled to admit that his rules for judging of the mortality of wounds are erroneous, and that the person may have survived for a longer or shorter period. There are several cases on record which show that wounds involving the common carotid artery and its branches, as well as the internal jugular vein, do not prevent a person from exercising voluntary power, and even running a certain distance. There is another circumstance which requires notice in relation to severe wounds in the *throat*—namely, that although a person may have the power of locomotion, he may not be able to use his voice so as to call for assistance. It sometimes excites surprise at an inquest, how a murder may, in this way, be quietly committed without persons in an adjoining room hearing any noise; but the fact is well known medically, that when the windpipe is divided, as it generally is on these occasions, the voice is lost. In *Reg. v. Gooch*, Northampton Assizes, Nov. 1877, it was proved that the prisoner had attacked the deceased with a knife, and had produced a severe wound in the arm. The medical evidence showed that it was a punctured wound about five inches in depth, involving the brachial artery. He lost a large quantity of blood, but a medical man arrived in time to tie the artery and thus prevent death from hemorrhage. In three days, however, gangrene set in, and he died from this secondary cause. Prisoner was held responsible, and found guilty of manslaughter. He had, it seems, aimed at the arm, thinking the stab would not be likely to cause death.

In reference to severe wounds involving bloodvessels, while we may allow that persons may survive for a sufficient time to perform various acts of volition and locomotion, yet the presence of a mortal wound, especially when of a nature to be accompanied by a great loss of blood, must prevent all *struggling* or violent exertion on the part of the wounded person; such exertion we must consider to be quite incompatible with his condition. A medical jurist may thus have it in his power to determine whether a mortal wound found on the deceased has or has not been inflicted for the purpose of murder. On wounds of other bloodvessels, whether arteries or veins, it is unnecessary to make any further remark. Death is generally owing to loss of blood, and the bleeding from a comparatively small vessel may prove fatal, according to its size, situation, and the state of the wounded person.

Death from the entrance of air into wounded veins.—In wounds of veins there is an occasional and a peculiar cause of death which requires a remark, namely, the entrance of air by the open mouth of the divided vessel. It has been long known that air injected into the jugular vein would destroy life by interfering with the functions of the heart; but the exact nature of this accident, as it occurs in operations, is not well understood. (Fergusson's "Surgery," p. 444.) According to some, the air rushes into the cavity of the vessel owing to atmospheric pressure during the expansion of the heart, while others believe it to be dependent on aspiration in the act of breathing; but in some alleged cases of this kind, death has been probably caused by loss of blood. When the bleeding is slight and the hissing sound is heard at the time of the incision, it may fairly be ascribed to the entrance of air. This opinion would be confirmed by the discovery of a frothy state of the blood in the right cavities of the heart.

From the experiments of M. Tillaux, it appears that the injection of air into the proximal or distal end of the femoral artery of dogs produces complete paralysis of the hind legs. A post-mortem examination showed hemorrhage and softening limited to a single point in the spinal cord. To explain the production of this effect by the injection of air into the distal end of the artery, he supposes that the air cannot pass through the capillaries into the veins, but finds its way by anastomosing arteries into the aorta, and thence into the arteries supplying the cord. After an injection of air into the carotids, patches of red softening are found in the different parts of the brain, but especially in the medulla oblongata and pons Varolii. The death of the animal is often very rapid. ("Medical Record," 1873.) According to some, death has arisen from want of contractile power in the right ventricle, occasioned by its distension with air; this may, no doubt, assist in producing the result, as over-distension of either cavity of the heart will cause paralysis of the walls. But according to Dr. Pavy the more immediate cause is the fact that air will not circulate through the capillaries like blood; the air, therefore, entering the capillaries of the lungs, blocks them up, and puts an end to the free circulation of the blood.

Wounds and ruptures of the diaphragm.—The diaphragm, or muscular partition between the chest and abdomen, is liable to be wounded either by weapons which penetrate the cavity of the chest or abdomen, or by the ribs when fractured through violent blows or falls; but, under any circumstances, wounds of this muscle are not likely to occur without implicating other important organs that are in contact with it. It is scarcely possible, therefore, to estimate the danger of these injuries abstractedly, as a medical opinion must materially depend on the concomitant mischief to the adjoining viscera. Slightly penetrating wounds of the diaphragm may heal like those of other muscular parts; and cases of this kind are on record. There is, however, especially when the wound is of a lacerated kind, a consecutive source of mischief which no remedial means can avert, namely, that after the wound has, to all appearance, healed, the life of a person may be cut short by the strangulation of a portion of the stomach or bowels in the half-cicatrized aperture. In a case of this description, when death occurs at a long period after the infliction of a wound, the

witness may probably be required to say—Whether the wound was the cause of death? or whether there were any other circumstances which would have caused or facilitated the production of a hernia. The degree of responsibility of an aggressor may materially depend upon the answers returned to these questions. *Phrenic hernia*, as this form of internal rupture is termed, is not by any means an unusual or unexpected fatal consequence of a wound of the diaphragm; and therefore it would appear at first sight that death, at whatever period this event may occur, should be referred to the original wound. But the case may present some difficulties, as it is possible that a slight blow on the stomach, received subsequently to the wound, or even any violent exertion on the part of the deceased, might have produced the fatal strangulation. A person may survive with a large phrenic hernia for a considerable period, and die from some other cause. It has been stated that a person is completely incapacitated and rendered incapable of exertion or locomotion by a rupture of the diaphragm. This statement, however, has been based on limited observation. The general effect of such an injury is to incapacitate a person, but cases are recorded in which, in spite of the rupture, a person has possessed the power of moving and walking to a considerable distance.

The most serious injuries to the diaphragm are unquestionably those which are produced by violent contusions or falls on the abdomen, at a time when the stomach and intestines are distended. In these cases the muscular fibres may be ruptured to a greater or less extent: but the bleeding is not considerable, rarely exceeding two, three, or four ounces. A uniform result of these *ruptures*, when extensive, is a protrusion of the stomach into the chest, with sometimes a rupture of its coats and extravasation of its contents. Severe lacerations of the diaphragm are more readily produced during the act of inspiration than during expiration—the fibres of the muscle being then stretched, and receiving, while in this state of tension, the whole of the force. According to Devergie, the rupture most frequently takes place in the central tendinous structure, where it is united with the left muscular portion above the crura. He has remarked that it occurs more commonly on the left side than on the right. (*Op. cit.*, vol. 2, p. 250.) It has been supposed that death would be an immediate consequence of this accident; but this view is not supported by facts. In a case of extensive rupture of the diaphragm, related by Devergie, in which the stomach and colon were found in the chest, the person lived nine months after the only accident which could have produced it, and then died from another cause. Besides the stomach, it sometimes happens that the liver, spleen, or intestines pass through the opening, and like it, these organs are liable to become strangulated: the lungs are at the same time so compressed that respiration is stopped, and asphyxia or suffocation may be an immediate result.

Direction of wounds in the chest.—In judging of the *direction* taken by wounds which traverse the chest from front to back, it is necessary to remember the great difference that exists in the level of the same rib anteriorly and posteriorly. This must be especially attended to when we are called upon to state the direction of a traversing wound from the description of it given by another. The point here referred to had an

important bearing in the case of a fatal gunshot wound, which was the subject of a criminal charge some years since. (Henke's "Zeitschrift," 1836.) It must not be forgotten that a wound immediately below the chest bone, will in its forepart involve the viscera of the abdomen, in the back part those of the chest, and in its central part it will traverse the diaphragm: owing to the great obliquity of the ribs, a straight line touching the upper edge of the sixth rib behind would be on a level with the upper edge of the third rib in front.

Wounds of the parietes of the abdomen.—*Incised and punctured* wounds, which affect the parietes or coverings of the abdomen, without penetrating the cavity, are not quite of so simple a nature as might at first sight be imagined. The danger is immediate if the epigastric artery be wounded; for a fatal hemorrhage will, in some instances, take place from a wound of this small vessel. Among the sources of danger from superficial wounds is inflammation, followed by suppuration beneath the tendinous membrane which covers the abdominal muscles. The matter formed is very liable to accumulate within the sheath of the muscles, and this may prove fatal unless proper treatment be adopted. The inflammation will sometimes extend to the peritoneum, and thus rapidly destroy life. As improper medical treatment may, in either of these cases, cause a superficial wound of the abdomen to take a fatal termination—so when a person stands charged with having inflicted such a wound, it will be necessary for a medical witness to consider how far the consequences of the act of the prisoner have been aggravated by wilful neglect or unskillfulness. But when these wounds take a favorable course and heal, there is an after-effect to be dreaded, namely, a protrusion of the viscera at the cicatrized spot, constituting ventral hernia. When the wound has involved the muscular fibres transversely to their course, the cicatrix which follows is commonly far less capable of resisting the pressure of the viscera within, than other parts of the parietes. A hernia may take place, and this, like other herniæ, if neglected, is liable to become strangulated, and lead to the destruction of life. The walls of the abdomen, owing to the protrusion of this cavity, are easily penetrated by pointed instruments, and it requires but a slight force to traverse them completely and wound the intestines. A slight wound may thus prove fatal by causing peritoneal inflammation.

Contusions are attended generally with far more serious effects on the cavity of the abdomen than on the chest. This arises from the coverings of the abdomen having less power to resist external shocks. In the first place, death may be the immediate result of a blow in the upper and central portions; no particular morbid changes may be apparent on inspection, and the violence may have been so slight as not to have produced any ecchymosed mark on the skin. Death has been ascribed in these cases to a fatal shock transmitted to the system through a violent impression produced on the great nerve centre—called the solar plexus. Some remarks have already been made on sudden death from blows on this part of the abdomen (p. 265). Travers, Alison, Watson, Cooper, and other writers on surgical injuries, have referred to cases of this kind as of not unfrequent occurrence. They are of considerable importance in a medico-legal point of view, as, in the absence of marks of physical

injury on the part struck, a jury might be led to doubt whether the blow could have been the cause of death. Some surgeons have thought that these cases have not been accurately observed, and that in those which terminated fatally, a more careful inspection would probably have shown visible changes in the organic structures. The fact, however, remains; persons have died soon after receiving severe blows on the upper part of the abdomen, and the medical men who have examined the bodies for the express purpose of detecting physical injuries, have not found any to record. Moreover, they have not found in any part of the body a natural cause of sudden death. (*Reg. v. Stone*, Durham Winter Ass., 1872.)

Blows on the abdomen, when they do not destroy life by shock, may cause death by inducing peritoneal inflammation. Violence of a severe kind applied to the abdomen is not always indicated by ecchymosis or injury to the skin. Effusions of blood in the sheaths and tendinous coverings of the muscles, may or may not be indicative of violence. One fact must here be borne in mind, to prevent mistakes in examining a body after death, namely, that blood may be found copiously effused in and around the abdominal muscles, quite irrespective of the application of violence. (Reid's "Physiological Researches," p. 511.) The absence of ecchymosis, or abrasion of the skin, in these cases, is sufficient to show that such extensive effusions are not caused by violence. Blows adequate to produce a laceration of the vessels and hemorrhage, would most probably be attended with ecchymosis—and some visible injury to the skin. At any rate, when such marks of violence are not visible, and there is no evidence of a blow having been struck, a witness would act wisely in declining to attribute the mere effusion of blood to the act of another person. Deeply penetrating wounds of the abdomen are generally fatal by reason of the injury done to the intestines and other organs.

Ruptures of the liver.—Blows on the abdomen may prove fatal by causing a rupture of the liver or other viscera, with extravasation of blood; and, as has been elsewhere stated, these serious injuries may occur without being attended with any marks of external violence (p. 265). Of all the internal organs, the liver and spleen are the most exposed to rupture, owing to their compact structure, which prevents them from yielding to a sudden shock, like the stomach and intestines. Ruptures of the liver may occur from falls or blows; but this organ may be ruptured merely by a sudden action of the abdominal muscles. This accident is more likely to occur when the liver has undergone fatty degeneration, or is in an otherwise diseased state. Ruptures of the liver are generally seen on the convex surface and in the anterior margin, seldom extending through the whole substance of the organ, but consisting of fissures varying from one to two inches in depth. The right lobe, from its size, is more usually affected than the left. Their usual direction is from before backwards, with a slight obliquity; they rarely intersect the liver transversely. The lacerated edges are not much separated, while the surfaces present a granular appearance. But little blood is met with in the laceration; it is commonly found effused in the lower part of the cavity of the peritoneum, or in the hollow of the pelvis, and is only in part coagulated. Ruptures of the liver, unless they run

far backwards and involve the vena cava or portal vein, are not in general attended with any considerable effusion of blood; but the bleeding, should this vessel be implicated, is sufficient to cause the instant destruction of life. Under other circumstances a person may survive some hours or days, as the blood sometimes escapes slowly, or it may be suddenly effused in fatal quantity as a result of violent exertion or of fresh violence applied to the abdomen. A man came into Guy's Hospital a few years since, in whom there were no immediate or urgent symptoms. He was sent away, and a few hours afterwards he was found dead in a cell at a police station. On inspection, the liver was lacerated nearly through its diameter, and as much as a basinful of blood was found effused in the cavity of the abdomen. ("Med. Times and Gaz.," 1864, 2, 527.) This large effusion must have taken place after the man had left the hospital. Ruptures of the liver generally prove fatal within forty-eight hours. On the other hand, death may be a slow result of this injury. In one case a man is reported to have died from a rupture of the liver, which had occurred from an accident eight days before. ("Med. Chir. Rev.," Jan. 1836, p. 296.) A case occurred to Dr. Wilks in which a patient in Guy's Hospital survived this serious accident ten days. The question has frequently arisen whether a person having a rupture of the liver can walk or exercise the power of locomotion. A case above mentioned shows that this injury does not prevent locomotion. Other cases illustrating these facts are recorded in medico-legal works. It appears to be, however, but little known to medical men. In *Reg. v. Chatfield*, Maidstone Winter Assizes, 1874, prisoner was proved to have maltreated his wife, by kicking her in the abdomen while she was in a drunken state. There was evidence that she had walked after the infliction of this violence. The liver was found ruptured, and there were extensive bruises over this part of the abdomen. The medical witness denied that the deceased could have walked with a ruptured liver, and therefore in his opinion the kicks did not cause the rupture. This was the main ground of the defence; but it was utterly inconsistent with all the other facts of the case. The prisoner was very properly found guilty of manslaughter.

Wounds and ruptures of the *gall-bladder* are necessarily attended with the effusion of bile. This irritant fluid finds its way into the cavity of the abdomen, and the person dies from peritonitis.

Ruptures of the spleen.—A rupture of this organ may be produced by bruising violence directly applied to that part of the abdomen in which it is situated, and as in other ruptures of the abdominal viscera from violence, the skin may not present any mark of contusion. In spite of this well-known fact, a case seldom comes to trial in which the defence is not made to rest upon the absence of marks of blows over the region of the ruptured organ. In *Reg. v. Chapman* (C. C. C., Sept. 1877), it was proved that the deceased, a woman, had sustained violence at the hands of the prisoner, and after death the spleen was found ruptured. There was no mark of a blow corresponding to the rupture; nevertheless the jury were satisfied with the medical evidence of the cause of death, and found the prisoner guilty of manslaughter.

When the spleen is in a diseased condition from softening or enlarge-

ment, it is easily ruptured by slight muscular exertion, as in suddenly turning the body to avoid a fall or a blow. Two fatal cases of this kind are reported by Dr. Stone. ("Brit. Med. Jour.," 1878, Sept. 28, p. 469.) This is an important fact in a medico-legal view. An assailant might be wrongly charged with manslaughter, while the rupture might be due to muscular pressure on a diseased spleen. (See also "Brit. Med. Jour.," May 4, 1878.) The healthy organ is only liable to rupture by direct violence.

Ruptures of the kidneys.—The *kidneys* are occasionally ruptured from violence; but this appears to be a rare accident. A rupture of the kidney may be produced without causing any prominent symptoms, and prove fatal in a few hours. It may be remarked generally that ruptures of the liver, spleen, and kidneys, unless attended with immediate and copious bleeding, are not inconsistent with a person having the power to move and walk. In a case which occurred at Guy's Hospital, a man retained the power of walking for some distance, although, on inspection after death, one kidney was found torn in halves from an accident.

Ruptures and wounds of the intestines.—Ruptures of the intestines sometimes occur from disease; and, in a case of rupture alleged to have been produced by violence, we must always take this possible objection to our opinion into account. The ruptured part of the bowel should be carefully examined, in order to see whether there are any signs of ulceration or softening about it. If not, and there is clear evidence of violence having been used, it is impossible to admit this speculative objection. If with the proof of violence there should also be a diseased condition of the bowel, we may be required to say whether this did not create a greater liability to rupture—a point which must be generally conceded. That a rupture of the intestines is not incompatible with the power of locomotion, is proved by a case related by Mr. Ellis, of Dublin, where the cæcum was ruptured; the man was able to walk after the accident, but he died in twenty-four hours. Other instances of this kind are reported by Henke. The ileum is observed to be most liable to rupture from accident. In 1861 a man was brought into Guy's Hospital. He was able to walk to his bed, and he did not appear to be seriously injured, although it was stated that a bale of wool had fallen on him. In the evening he became collapsed, and he died twelve hours after his admission. On inspection, about a pound of blood was effused in the abdomen, and a portion of the ileum was found lacerated—the laceration extending into the mesentery and including the bloodvessels. The laceration was about an inch and a half long, and the bowel was divided not quite through. The intestines were much matted together by lymph and blood, the result of peritoneal inflammation. There had been only slight extravasation of the contents. ("Med. Times and Gaz.," Sept. 1861.) I am indebted to Dr. Croker King for a report of two fatal cases of ruptured jejunum, one arising from a kick on the abdomen and the other from an accidental fall. Dr. King has observed that persons who have sustained this injury retain for a time the power of locomotion and muscular exertion.

A case of rupture of the descending colon from the kick of a horse,

proving fatal in eighteen hours, is recorded in the "British Med. Journal" for Oct. 1879 (p. 652). There was no mark of external bruise on the abdomen, and the person who sustained the injury was able to walk nearly a mile after receiving it. Two other cases of a similar kind are reported in the same journal, p. 653.

As in ruptures of the bladder and other hollow viscera of the abdomen, so in ruptures of the intestines caused by the direct application of violence, it often happens that there are no external marks of violence. A man was thrown from, and trampled on by his horse. There was no mark of contusion on the abdomen, but the jejunum was ruptured. This proved fatal. ("Brit. Med. Jour.," Oct. 1879, p. 535.)

Punctured wounds, which merely touch the bowels without laying open the cavity, are liable to cause death by peritonitis. These injuries to the intestines sometimes destroy life by shock; there is but little blood effused, and the wounded person dies before peritonitis can be set up. Severe wounds of the intestines may, however, be inflicted almost without the consciousness of the individual, and the wounded person may be able to walk a considerable distance. ("Med. Gaz.," vol. 46, p. 24.)

Wounds and ruptures of the stomach.—Wounds and ruptures of the stomach may cause death by shock; ruptures commonly give rise to severe pain, which of itself is sufficient to bring about rapid dissolution. It is proper to state, however, that the stomach may be ruptured from spontaneous causes, as in cases of ulceration resulting from disease; but sometimes there is no morbid cause apparent. Penetrating wounds of the stomach generally prove rapidly mortal; they seldom form a subject for medico-legal investigation. A singular case was tried at the Norwich Assizes in 1832, in which a man was charged with the murder of his wife by throwing at her a red-hot poker. The weapon completely perforated her stomach, and the woman died in six hours. It might be a question whether this was a *wound* in the common sense of the term—it was an injury compounded of a burn, puncture, and laceration.

Ruptures of the bladder.—This injury, which has on many occasions given rise to medico-legal discussion, is frequently the result of blows or kicks on the lower part of the abdomen. The principal questions in reference to the accident are: Was the rupture the result of wilful violence, or of an accidental fall? or, did it proceed from spontaneous causes, as from over-distension? The spot in which rupture commonly takes place is in the upper and back part, where the bladder is covered by the peritoneum. This aperture is sometimes large, at others small, but the effect is that the urine is effused, and death takes place sooner or later from peritoneal inflammation. It is commonly stated that ruptures, when attended with extravasation of urine into the peritoneal cavity, are uniformly fatal; but if the rupture occurs in the under part of the bladder, or the urine finds its way into the cellular tissue, the medical opinion is not so unfavorable. The usual period at which death occurs from this accident is in from three to seven days; but Mr. Ellis met with a case in which the person did not die until the fifteenth day. The cause of death is generally peritoneal inflammation; but a person may die suddenly from this injury, as a simple result of shock.

When ruptures of the bladder are produced by blows they are rarely

accompanied by marks of ecchymosis, or of injury to the skin. Thus, then, there may be no means of distinguishing, by external examination, whether a rupture was really due to violence or to spontaneous causes. Those who are unacquainted with this fact might be disposed to refer the rupture to disease, on the supposition that violence should always be indicated by some visible external injury; but there are numerous cases on record which show that this view is erroneous. (See “Ann. d’Hyg.,” 1879, 1, p. 477.) Rupture of the bladder has been caused by a fall in wrestling. It proved fatal in four days. (*Reg. v. Warburton*, Carlisle Lent Assizes, 1876.)

As an attempt may be made, in cases in which death has resulted from this injury, to refer rupture of this organ to *natural causes*, it may be observed that this is a very unusual occurrence; a rupture is almost always the result of violence directly applied to the part while the organ is in a *distended* state. A *spontaneous rupture* may, however, occur: 1. When there is paralysis, with a want of power to expel the urine. 2. When the bladder is ulcerated or otherwise diseased. 3. When there is an obstruction in the urethra from stricture or other causes. The causes of spontaneous rupture are easily recognizable by ascertaining the previous condition of the deceased, or by examining the bladder and urethra after death. If a man were in good health prior to being struck; if he suddenly felt intense pain, could not pass his urine afterwards, and died from an attack of peritonitis in five or six days; if, after death, the bladder was found lacerated, but this organ and the urethra were otherwise in a healthy condition, there can be no doubt that the blow must have been the sole cause of rupture and death. In such a case, to attribute the rupture to spontaneous or natural causes would be equal to denying all kind of causation. As to the absence of marks of violence externally, this would be a difficulty only to those who had not previously made themselves acquainted with the facts attending this and other accidents affecting the viscera of the abdomen. Nevertheless, a medical witness must be prepared to hear the same line of defence continually brought forward, as it is always the object of a counsel to make the best of a case for the prisoner. With medical facts, opinions, and doctrines he does not concern himself, so long as they do not serve his purpose. A diseased state of the bladder might probably diminish the responsibility of an accused person for the consequences; therefore the state of this organ should be closely looked to on these occasions. A distended state of this organ can be no mitigatory circumstance, since it is only when the bladder is in this condition that rupture is liable to occur. This can hardly be regarded as an abnormal condition of the organ. An accidental fall forwards over a hard surface when the bladder is distended with urine may lead to rupture. The person generally experiences at the time intense pain in the lower part of the abdomen, and there is an inability to pass the urine. Although a man is liable to be rendered powerless on sustaining a rupture of the bladder from a heavy blow or fall, there are several well-authenticated cases on record which prove that a man may walk some distance, and move about even for two or three hours afterwards.

In punctured and incised wounds of the bladder the urine is imme-

diately extravasated, but in gunshot wounds the extravasation does not commonly take place until the sloughs have separated. Thus, life may be protracted longer in cases of gunshot, than under other wounds of the bladder. For the discovery of extravasated liquids or blood in wounds and other injuries of the abdominal viscera, we must look to the cavity of the pelvis, as it is here that, for obvious reasons, such liquids have a tendency to collect.

Wounds of the genital organs.—Wounds of these organs do not often require the attention of a medical jurist: such wounds, whether in the male or female, may, however, prove fatal to life by excessive bleeding. Self-castration or mutilation is sometimes observed among male lunatics and idiots. When timely assistance is rendered, a fatal result may be averted. Dr. Demarquay met with a case in which a man in a fit of intoxication cut off the whole of his genital organs with a razor. He lost much blood, from the effects of which he died on the following day, ("Lancet," 1872, 2, p. 10.) The practice of circumcision on infants is sometimes followed by fatal results. Dr. Schwartz, of Vienna, met with two cases of boys, eight days old, who were submitted to this rite. They both died of phlegmonous inflammation, one five days, and the other twenty-five days after the operation. ("Lancet," 1870, 2, p. 471.) Another fatal case is reported in the return of the Registrar General for 1871.

Incised, lacerated, or even contused wounds on the *female* genitals may prove fatal by loss of blood, not from the wound involving any large vessel, but from the numerous small vessels which are divided. When deeply *incised* wounds are inflicted upon the genital organs of either sex, the fact of their existence in such a situation at once proves wilful and deliberate malice on the part of the assailant. Accident is wholly out of the question, and suicide is improbable, except in cases of confirmed idiocy, lunacy, or intoxication. Such wounds require to be carefully examined; for the proof of the kind of wound, when fatal, may be tantamount to a proof of murder. A practitioner may be sometimes required to determine whether wounds affecting the female organs have resulted from accident, have been self-inflicted, or inflicted by others with homicidal intention. [In the Oyer and Terminer of Meigs County, Ohio, February Term, 1866, Mary Broderick was indicted for having caused the death of her husband by "purposely and maliciously with her right hand grasping and wrenching the penis of the said Patrick Broderick with intent to inflict a mortal wound; by means whereof, the urethra, with the corpus spongiosum and corpus cavernosum, was broken and severed, and from the effects thereof the said Patrick Broderick died on the eleventh day thereafter." The defendant was found guilty of manslaughter by the jury. A motion for a new trial was made, which had not, when the case was reported, been disposed of. See "Cincinnati Journal of Medicine," July, 1866, p. 316, where this case is reported, together with instances of similar injury resulting from accident, in an article by Dr. Geo. C. Blackman. —P.] Accidental wounds of the genitals, unless all the circumstances are known, may sometimes resemble those produced by design. A girl, æt. 6, fell from a tree with her legs apart upon one of the sharp-pointed shoots below, about half an inch

thick. This entered the vagina, and passing through its posterior wall, broke off. A woman removed the wood with some difficulty. The child died in twenty-eight hours from peritonitis. ("Lancet," 1871, vol. 2, p. 74.) Had this child been found dead with the wood in her body, there might have been some difficulty in assigning an accidental origin to such an injury. (For remarks by Toulmouche on the wounds of the male genital organs, see "Ann. d'Hyg.," 1858, vol. 2, p. 110; and for cases in which such wounds were homicidally inflicted upon males, see "Ann. d'Hyg.," 1848, vol. 1, p. 443; also 1865, vol. 1, 56; and for a case which led to a trial for the murder of a woman, see "Med. Gaz.," vol. 44, p. 813.) The distinction of a homicidal from an accidental or self-inflicted wound on the female organs is sometimes attended with great difficulty. In *Reg. v. Green*, Derby Winter Assizes, 1872, the medical evidence established that there was a punctured wound of the genitals in a female which had caused death by hemorrhage; but it could not be clearly shown whether it was the result of accident or homicide. The case of the girl mentioned above shows that unless all the circumstances are known, an accidental injury to the genital organs may present the characters of homicidal violence.

In another part of this work will be found reported a case in which an accidental wound on the genital organs of a girl, did not prove fatal, and an attempt was made by the parents to attribute it to intentional violence. Certain persons were charged with maliciously wounding the girl, but a proper surgical examination of the wound showed that this was a false charge.

It has been said that lunatics, idiots, or intoxicated persons might inflict upon themselves wounds unlike those produced in ordinary attempts at suicide. A case was tried at Glasgow, in April, 1873, in which a man was charged with the murder of his wife. They were both intoxicated when they went to bed. The prisoner during the night called to one of his daughters to come to her mother, who had been taken ill. She found her lying on the floor, and blood flowing from her, and there was also some substance which proved to be intestine. A surgeon who was called found a clean-cut wound in the vagina, through which a portion of intestine, with clean-cut ends, protruded. Seven feet and seven inches of intestine had been cleanly cut off in three pieces; they were not ragged. The woman died at the end of a week from loss of blood and peritonitis. The man was charged with this act, but were these injuries self-inflicted, or were they the result of homicide? It was admitted that suicide was possible, but not probable. The woman's hands were covered with blood, but the man's were not. The man was of good character. There was no motive, and they had been married forty years, and were much attached to each other. There was no motive for suicide and no motive for murder. No weapon was found with which the wound could have been inflicted. Two pocket-knives were in the trousers of the man, but there was no mark of blood upon them, and it was not thought probable that the wound had been inflicted with either. The woman had made a dying declaration, obviously false, which was that the wound had been caused by her falling over a chair; that no person injured her, and

that she and her husband had always been on friendly terms. The jury returned a verdict of "not proven." ("Lancet," 1873, vol. 1, p. 6)

A remarkable case of wounded genitals in a female was the subject of a trial for murder at the Stafford Winter Assizes, Jan. 1879—*Re Painter*. The medical witness for the prosecution deposed that on going aside the labia he found a *distinctly incised* wound an inch and half in length and three-quarters of an inch deep. The pudic artery was severed as well as a branch of the iliac artery. The wound was clean, not torn, apparently made with a sharp instrument. The clitoris on examination showed no sign of an outward stab, but they were saturated with blood. Two medical witnesses who had not seen the wound were called for the defence. They thought that such a wound might have resulted from an accident, by the woman sitting down on some sharp, such as glass. It was contended for the prosecution that the prisoner had produced the wound with a knife, thus causing fatal hemorrhage, but no knife could be found although the occurrence was recent. The woman had evidently bled over a large surface of groin and had died from exhaustion. On the medical doubt touching the origin of the wound the prisoner was acquitted. As the incised wound was inside the labia, and these were not wounded, upon either theory the clothes of the woman must have been raised, and if a knife had been used it must have been deliberately carried into the vagina. On the supposition that a pointed piece of glass had caused the wound as the result of an accidental fall, she must have fallen with the clothes raised so that the glass would penetrate the vagina without injuring the labia, but no glass could be found on the spot, nor was it at all probable that such an accident could have taken place.

Contused wounds on the female genitals may prove fatal by the laceration of parts leading to great loss of blood. Several trials for slaughter have taken place, in which this was proved to have been the cause of death. In *Reg. v. Lewis* (Maidstone Lent Ass., 1876), the prisoner was charged with having caused the death of his wife by kicking her in the lower part of the abdomen. She died in a few days from inflammation. The medical witness considered that violence was the cause of death, although he would not positively swear to it. Lord Coleridge thereupon made this important observation to the jury: "It is not the case there may be the absence of absolute demonstration which is the nature of human affairs can hardly ever be had, that, therefore, you should not act on your conviction." Did the violence cause death? What else could have caused it? What other cause is suggested? What could have caused it? The prisoner was convicted, and sentenced to penal servitude.

There may be such a loss of blood in these cases as to destroy life, although no large bloodvessel may be implicated in the injury. A contused wound on the vulva may occasionally present an ambiguous appearance, and be mistaken for an incised wound. When the soft parts of the body are struck by a blow or kick, if there is a bony surface beneath, a longitudinal rent, resembling a cut, may appear as a result of the blow being received by the bone. A kick on the vulva, or a fall on this part, may produce a similar injury, and unless carefully examined, may

to the erroneous inference that a weapon has been used for its production. It is well known that some women are subject to frequent discharges of blood from the genital organs from natural causes. When the bleeding immediately follows a blow, and the woman has not been subject to such a discharge, the fair presumption is that violence was the cause ; but when the flow of blood appears only a long time after the alleged violence, of which no traces can be seen, it is most probably due to natural causes. A case of this kind has been communicated to me by Mr. Procter, of York. There was no difficulty in giving an opinion that the flow of blood was *not* due to violence.

It may be alleged in defence, that the injuries found on the body were inflicted *after death*, and not while the deceased was living. Kicks or blows on the vulva, if they destroy life at all, cause death by copious effusion of blood. Violence to this part after death would not produce such an effusion as would account for death. There are also other distinguishing characters, which have been elsewhere pointed out.

CHAPTER XXXV.

FRACTURES.—PRODUCED BY A BLOW WITH A WEAPON OR BY A FALL.—BRITTLENESS OF THE BONES.—FRACTURES CAUSED BY SLIGHT MUSCULAR EXERTION.—FRACTURES IN THE LIVING AND DEAD BODY.—HAS A BONE EVER BEEN FRACTURED ?—LOCOMOTION.—DISLOCATIONS FROM VIOLENCE OR NATURAL CAUSES.—MEDICAL OPINIONS.—ACTIONS FOR MALAPRAXIS.

FRACTURES.

FRACTURES of the bones have some important bearings in relation to medical jurisprudence. They may result from falls, blows, or the spontaneous action of muscles.

Causes.—Questions are sometimes put,—whether a particular fracture was caused by an accidental fall or a blow ; and if by a blow, whether by the use of a weapon or not. It is obvious that the answers must be regulated by the circumstances of each case. In examining a fracture, it is important to determine, if possible, whether a *weapon* has or has not been used, and this may be sometimes ascertained by the state of the parts. It is a common defence, on these occasions, to attribute the fracture to an accidental fall. Fractures more readily occur from equal degrees of force in the old than in the young, and in the young rather than in the adult ; because it is at the adult period of life that the bones possess their maximum degree of firmness and solidity. The bones of aged persons are sometimes very *brittle*, and slight violence will then produce fracture. This has been regarded as an extenuating circumstance, when the fracture produced by a slight blow was followed by death. Certain diseases, such as syphilis, arthritis, cancer, scurvy, and rachitis, render bones more fragile ; but they are sometimes preternatu-

those who are at the time affected with a mortal disease there is no attempt at reparation. According to Villermé, the callus assumes a cartilaginous structure in from sixteen to twenty-five days; and it becomes ossified in a period ranging from three weeks to three months. It requires, however, a period of from six to eight months for the callus to acquire all the hardness, firmness, and power of resisting shocks possessed by the original bone. A force applied to a recently united bone will break it through the callus or bond of union, while after the period stated the bone will break as readily through any other part. It is generally assumed that the period required for the union of a simple fracture is, for the thigh-bone, six weeks; for the tibia (leg), five weeks; for the os humeri (arm), four weeks; and for the ulna and radius (forearm), three weeks; for the ribs, about the same period; but cases have been known in which the ribs had not perfectly united in two months, and in some fractures of the other bones, it was found that union had not taken place in four months. In a case which occurred to Dr. Reid, a fracture of the tibia, the principal bone of the leg, healed in three weeks.

Has a bone ever been fractured?—This question is sometimes put in reference to the *living* body. It is well known that a bone seldom unites so evenly that the point of ossific union is not indicated by a node or projection. Some bones are so exposed as to be well placed for this examination, as the radius, the clavicle, and tibia,—these being but little covered by skin; in others, the detection is difficult. It is impossible for us to say when the fracture took place; it may have been six months or six years,—as, after the former period, the bone undergoes no perceptible change. These facts are of importance in relation to the *dead* as well as to the *living*; since they will enable us to answer questions respecting the identity of skeletons found under suspicious circumstances; and here medical evidence may take a wider range, for a fracture in any bone may be discovered, if not by external examination, at least by sawing the bone longitudinally through the suspected broken part, when, should the suspicion be correct, the bony shell will be found thicker and less regular in the situation of the united fracture than in the other parts. So, in such cases, it will be easy to say whether a fracture is recent or of old standing.

Locomotion.—With respect to the power of *locomotion* after a fracture, it may be observed, that when the injury is in the arm, or in the ribs—unless many of the ribs are broken or the fractures are on both sides—a person may be able to move about, although he is unfitted for struggling or making great exertion. Fractures of the leg generally incapacitate persons from moving, except to short distances. See case by Syme, “Ed. Med. and Surg. Journal,” Oct. 1836; also another in which one bone of the leg was fractured, and a power of walking some miles was retained. (“Amer. Journ. Med. Sci.,” Oct. 1845, p. 484.) The reader will find additional information on this subject in the “Ann. d’Hyg.,” 1839, 2, p. 241; 1844, 2, p. 146; and in Friedreich’s “Ueber die Knochen in forensischer Beziehung,” Ansbach, 1853.

DISLOCATIONS.

Dislocations are not frequent in the old, or in those persons whose bones are brittle. They rarely form a subject for medico-legal investigation. A witness is liable to be asked, what degree of force, and acting in which direction, would produce a dislocation,—questions not difficult to answer. These injuries are not dangerous to life, unless of a compound nature, when death may take place from secondary causes. A dislocation which has occurred in the *living body* may be known after death by a laceration of the soft parts in the neighborhood of the joint, and by the copious effusion and coagulation of blood. For an account of the appearances presented by a dislocation of the shoulder four days after death, see “*Med. Gaz.*,” vol. 31, p. 266. If of old standing, a dislocation would be identified by the cicatrices in surrounding structures. Dislocations may occur from *natural causes*, as from disease and destruction of the ligaments in a joint; also from violent muscular spasm during an epileptic convulsion. Dr. Dymock met with an instance of dislocation of the shoulder forwards during puerperal convulsions. (“*Ed. Med. and Surg. Journal*,” April, 1843; see also “*Lancet*,” April, 1845, p. 440.) A power of *locomotion* may exist, except when the injury is in the lower limbs; but it has been observed, that for some time after a dislocation of the hip-joint, considerable power over the limb remains; it is only after a few hours that the limb becomes fixed in one position. Exertion with the dislocated member is in all cases out of the question.

Detection of fractures. (Malapraxis.)—There are certain fractures of an obscure kind which closely resemble dislocations. This has been pointed out by Sir A. Cooper, in relation to fractures of the anatomical neck of the os humeri (arm-bone). (“*Guy’s Hosp. Rep.*,” No. 9, p. 272.) This accident might easily be mistaken for a dislocation of the shoulder. (“*Med. Gaz.*,” vol. 36, p. 38.) In attempting to reduce the bone, the head continually falls back into the axilla. In such a case an action for malapraxis might be brought against a surgeon, and heavy damages recovered. It could only be by a dissection of the part after death that the real nature of the case would be ascertained. It is requisite, therefore, that great caution should be used in giving an opinion. The same observations apply to fractures of the neck of the thigh-bone, although with less force, because this is a more common accident in old persons. It is well known that fractures and dislocations, when cured, are often attended with some slight *deformity* of the limbs, or with some impairment of its functions. This result is occasionally inevitable under the best treatment; but it is commonly set down as a sign of unskilfulness in a medical attendant. An action for malapraxis is instituted, and, in spite of good evidence in his favor, the surgeon is sometimes heavily fined for a result which could not be avoided. There is often great injustice in these proceedings, and the mischief can be remedied only by referring the facts to a competent medical tribunal, which alone should be empowered to decide whether or not unskilfulness had really been shown in the management of a case. The present system of allowing each party to select his own medical witnesses invariably leads to a conflict of opinion and evidence.

[It should not be forgotten that shortening of the leg frequently occurs after severe contusions of the hip, *without any fracture*, arising from interstitial absorption of the neck of the femur. This is well illustrated by Mr. Gulliver, in "Eden. Med. Journ.," vol. xlv. 1836; also by Sir J. Paget, in "Brit. Med. Journ.," Feb. 19, 1870. This accident has given rise to an action for alleged malapraxis. See "Philadelphia Med. Times," Dec. 1, 1870.—R.]

[The proof of ordinary care and skill and judgment exercised in the treatment of a case is a sufficient defence in law against a claim for damages on account of alleged malpractice; but it is too apt to fail with the juries in this country, and will not protect the victim of a prosecution from its attendant expenses. Although our judges, in many instances, have done their best to secure just verdicts, the juries are notoriously stupid and unjust; so that the only real security to the attendant surgeon is an indemnity bond against all consequent prosecution, to be previously assumed by the patient.—H.]

CHAPTER XXXVI.

GUNSHOT WOUNDS.—IN THE LIVING AND DEAD BODY.—WAS THE PIECE FIRED NEAR OR FROM A DISTANCE?—ACCIDENTAL, SUICIDAL, OR HOMICIDAL WOUNDS.—POSITION OF THE WOUNDED PERSON WHEN SHOT.—WOUNDS FROM SMALL SHOT.—WOUNDS FROM WADDING AND GUNPOWDER.

GUNSHOT wounds are of the contused kind, but they differ from other wounds in the fact that the vitality of the parts struck by the projectile is destroyed, and this leads ultimately to a process of sloughing.

The medico-legal questions which arise out of gunshot wounds, are similar to those which have been examined in relation to other wounds. They are *dangerous to life*, especially when they penetrate or traverse any of the great cavities of the body. Death may take place directly, either from loss of blood or from shock; although immediate or copious bleeding is not a common character of these injuries. Death from shock is occasionally witnessed. Indirectly, these wounds are attended with much danger; sloughing generally takes place uniformly throughout the whole of the parts perforated, and inflammation or fatal bleeding may cut short life. If the person survives the first effects, he may die at almost any period from suppurative fever, erysipelas, gangrene, or from the results of operations absolutely required for his treatment. Gunshot wounds may thus destroy life after long periods of time. A medical witness may be asked whether the wound was inflicted *shortly before or soon after death*. It is by no means easy to answer this question, unless the bullet has injured some vessel, when the effusion of blood and the formation of coagula, will indicate that the person was living when it was received. If a gunshot wound has been produced in a dead body, no blood will be effused unless the bullet strikes a large vein.

If the person survives the injury, and the bullet can be felt in an accessible spot, it should, if possible, be removed. (See the case of *Reg. v. Kelly*, p. 272.) In addition to the use of Nélaton's probe (unglazed china) for detecting a bullet which was used on that occasion, a chemical method has been suggested. Lint moistened with vinegar, and secured to a flexible stem, may be introduced into the wound, and allowed to remain for a short time in contact with the supposed bullet. It is then withdrawn, and placed in contact with a solution of iodide of potassium. If a leaden bullet was in the wound, it would produce a precipitate of the yellow iodide of lead (p. 166). ("Lancet," Aug. 1872; "Amer. Journ. Med. Sci.," Oct. 1872.) M. Desneux has employed this method in three cases.

Was the piece fired near or from a distance?—A gunshot wound produced by the muzzle of a piece being placed near to the surface of the body, has the following characters: There may be two apertures, the one of *entrance* and the other of *exit*; but it sometimes happens that the bullet lodges and does not pass out. The edges of the aperture of entrance are generally torn and lacerated, and appear blackened, as if they had been burnt; this arises from the heat and flame of the gunpowder at the moment of explosion. The skin is often ecchymosed, and is much discolored by the powder; the clothes covering the body are blackened by the discharge, and sometimes ignited by the flame. If the muzzle of the piece was not in immediate contact with the part struck, the wound is rounded; but if there has been direct contact, the skin, besides being burnt, is torn and much lacerated. The bleeding is usually slight, and when it occurs, it is more commonly observed from the orifice of exit than from that of entrance. It should be remarked that the aperture of entrance is round only when the bullet strikes point blank or nearly so. If it should strike obliquely, the orifice will have more or less of an oval or valvular form; and by an observation of this kind we may sometimes determine the relative position of the assailant with respect to a wounded person. Supposing the bullet to have been fired from a moderate distance, but so near as to have had sufficient momentum to traverse the body, then the appearance of the wound will be different. The *orifice of entrance* will be well defined, round or oval, according to the circumstances; the skin slightly depressed, the edges presenting a faintly bruised appearance; but the surrounding parts are neither blackened nor burnt, and they do not present any marks of bleeding. In these cases the *orifice of exit* is large, irregular, the edges somewhat everted, and the skin lacerated, but free from any appearances of blackness or burning; it is generally three or four times as large as the entrance aperture. The orifice of entrance is, however, usually large and irregular when a bullet strikes near the extremity of its range. [Surgical authorities generally assert that the entrance orifice is somewhat smaller than the exit orifice. Prof. Casper, however, declares that the former is *always* the larger, adding that "all the more recent original observers very properly unite in this conclusion, which is the opposite of that which was formerly maintained."—R.]

The entrance aperture may have the appearance of being smaller than the projectile, owing to the elasticity of the living skin. ("Ann. d'Hyg.,"

1839, t. 2, p. 319.) It is the same with the aperture in the dress, when this is formed of an elastic material. According to Dupuytren, the hole in the dress is always smaller than that made by a bullet in the skin. These points should be remembered in fitting projectiles to wounds which they are supposed to have produced.

In recent times bullets of a novel kind have been employed, and the appearances presented by gunshot wounds have differed accordingly. Professor Busch, of Bonn, has directed attention to this point. He found that a chassepot bullet, shot from a short distance into the human body, made a simple aperture of entrance, but that its aperture of exit was larger than a fist, and that there was very extensive fissuring and fracturing of bone. Bullets of soft lead produced larger apertures of exit than those made with hard lead. There is no essential difference in the action of bullets on the living and dead body as to appearance and extent. The wounds are not more extensive in the living than in the dead. ("Med. Times and Gaz.," 1874, 1, 616.)

Bullet wounds and stabs.—It would hardly be supposed possible that a gunshot wound would be mistaken for a stab with a bayonet or dagger, and yet a well-marked case, involving such a mistake, is reported ("Friedreich's Blätter," March and April, 1879). A man was found dead with a penetrating wound of the chest. There was much blood effused. The lung, pulmonary artery and aorta were wounded. Death must have been instantaneous, and it was assigned by the examiners to a stab with a narrow-bladed, sharp-pointed dagger. It bore the character of a homicidal stab perpetrated by another. Some time afterwards a man confessed that he had shot the deceased with a revolver while he was lying on the grass, and this was confirmed by a further examination of the body. A round hole, corresponding to the wound, was found in the coat, and a conical bullet about the third of an inch in diameter, was found lodged in one of the dorsal vertebræ. The discharge had not taken place near enough to cause any marks of singeing or burning, and the smallness of the bullet, and its shape, accounted for the stab like appearance of the wound.

The question whether a piece was fired *near to*, or *at a distance from*, the wounded person, may be of some importance either on a charge of homicide, or of alleged suicide. Two persons may quarrel, one having a loaded weapon in his hand, which he may allege to have been accidentally discharged, and to have killed the deceased. If the allegation is true, we ought to find on the body the marks of a near wound: if, however, its characters were such that it had obviously been produced from a distance, and, therefore, after the quarrel, medical proof of the fact might imply malice, and involve the accused in a charge of murder. The following case occurred in Ireland in 1834: A tithe collector was tried for the murder of a man by shooting him. It appeared in evidence that the prisoner, while on duty, was attacked by the deceased and two of his sons, and he drew a pistol to intimidate them. He was dragged off his horse by these persons, and during the scuffle, it is supposed, the pistol was discharged accidentally and inflicted a wound on the deceased, of which he died shortly afterwards. The sons of the deceased swore that the prisoner took a deliberate aim, and fired the pistol at their father

when at some distance; and a priest came forward to depose that such was the dying declaration of the deceased. From some doubt of the truth of this story, the body, which had been carelessly inspected in the first instance, was ordered to be disinterred. It was again examined by a surgeon, who was enabled to swear positively that the pistol must have been fired close to the body of the deceased, and not at a distance, since there were the marks of powder and burning on the wrist. Hence it clearly followed that the pistol had not been discharged at a distance, but during the scuffle, either by accident or in self-defence. The prisoner was acquitted, and the parties who had appeared as witnesses against him were convicted of perjury.

It has been said that when a bullet is fired near, it commonly traverses the body; and therefore it has been rather hastily assumed that when there is only one external wound, and the bullet has lodged in the body, this is a proof that the piece has been fired from a distance. This inference is, however, erroneous. A bullet may be fired close to a person, and yet not traverse the body, either from its impulsive force not being sufficiently great, or from its meeting with great resistance in its course. Many cases might be cited to show that in near wounds produced by suicides and murderers, the bullets have not always traversed the body. In suicide, when the piece is discharged into the mouth, the projectile often lodges in some part of the head. It is not in the power of a witness to say, from the mere fact of a bullet lodging or traversing, whether the assassin was far off or near, at the time that the deceased was wounded. The latter point may be sometimes readily determined by the marks of injury and burning about the skin and dress. When a gun or a pistol is discharged at the distance of three or four yards from the person, it will not, of course, produce those marks of blackening, burning, and bruising on the skin which are found when the muzzle is within a few inches of the body. A wound which does not present these appearances may remove the suspicion of suicide, and create a strong presumption of homicide. Dr. Lachèse found that in firing a gun at the distance of four feet, the skin was only partially blackened. It would be very important in a case of this kind to notice the *direction* of the wound as well as the relative position of the assailant and assailed, as stated by witnesses or deduced from circumstances. When a ball traverses the body, it sometimes happens that the two apertures are opposite to each other, although the ball may not have taken a rectilinear course between them, but have been variously deflected by the subjacent soft parts. This deflection of a ball from a rectilinear course is met with in those cases in which it happens to strike obliquely a curved surface, and it is found that when the ball enters and does not pass out, its course is often circuitous, so that it is not always easy to say in what part of the body it will be found.

A witness may be asked: When was the gunshot wound inflicted, and how long did the wounded person *survive* after receiving it? Like other wounds, a gunshot wound undergoes no change for eight or ten hours after its infliction. Our judgment in reference to these questions may be assisted by observing the parts which are involved, although we cannot always infer from the quantity of blood found near to a body that

the bleeding was an immediate consequence of the wound, or that the whole of the blood was effused at once. We cannot, then, always affirm that the deceased could not have moved or exerted himself in some degree after receiving it. The exertion thus made subsequently to his being wounded, may have actually caused the fatal bleeding.

Suicidal and homicidal gunshot wounds.—When it is doubtful whether the wound was the result of suicide or homicide, the point may be sometimes determined by paying attention to its situation and direction. *Suicidal* gunshot wounds are almost always directed to a vital part—to the heart or to the brain; they possess those characters which belong to wounds inflicted near to the body. The skin is discolored or burnt, the wound wide and lacerated, the hand which discharged the weapon often blackened, and sometimes still grasping the pistol. The ball may or may not have traversed, as this will depend on the momentum which it derived from the charge, and the resistance which it experienced.

Accidental gunshot wounds bear the characters of near wounds; they may touch vital parts, but, if the body has not been disturbed, the presence or absence of design in the infliction of a wound is commonly made apparent by the relative position of the body and the weapon. They frequently arise from persons drawing the charges of guns or pistols with the muzzles pointed towards them, and they are then situated in front; at other times they are produced by persons pulling towards them through hedges, or dragging after them, loaded guns. In the latter case the wound is behind, and it may strongly resemble a homicidal wound, although the circumstances under which the body is found generally suffice to explain the matter. (See "Ann. d'Hyg.," 1860, t. 1, p. 443.) A case was communicated to me by Dr. Mackintosh, of Downham, in September, 1876, in which a loaded gun had been placed on the top of a corn-bin in a stable. A fowl trod upon the trigger and thus fired the gun. It seriously wounded an old man who was near. This shows by what a strange coincidence a man may be found shot with his own gun, and how difficult it might be to reconcile the discharge of the gun with any accidental circumstances. In *suicide* there is commonly strong evidence of design; in accident, all evidence of design is wanting. Suicides sometimes make use of extraordinary weapons, or use weapons in an extraordinary manner.

Position of the wounded person when shot.—Did the deceased receive the shot while standing, falling, or lying down? Was the piece, when discharged, pointed from the shoulder?—These questions can only be answered by reference to the particular circumstances of the case. In general, when a person is shot while standing, and the piece is pointed from the shoulder, the wound is more or less transverse; but due allowance must be made for the deflection of balls after penetration. Was the deceased shot while running away, or when approaching the person who fired?—This question is answered by observing, in the case of a traversing wound, in which alone any difficulty can arise, whether the entrance-orifice be situated in front or behind.

Wounds from small-shot.—Death is sometimes occasioned by small-shot, and here several medico-legal questions present themselves. Small-shot may act in two ways: 1. It either strikes without spreading, in

which case the discharge is always near the person, and its action is much more dangerous than that of a single ball, because it produces extensive lacerations ; or 2. It strikes after it has spread, and here the discharge must have been distant, and comparatively little mischief is done. Dr. Lachèse ascertained, by many experiments on dead bodies, that in order to produce with small-shot, a round opening somewhat resembling that produced by a bullet, the discharge should take place point-blank at the distance of about ten or twelve inches from the surface of the body. When the distance was from twelve to eighteen inches, the opening made was irregular, and the borders were much lacerated ; at thirty-six inches, a central opening was entirely absent, and the surface of the body was covered with shot. The effect after this was found to depend on the distance, the goodness of the gun, and the strength of the charge (" Ann. d'Hyg.," 1836, p. 386) : but the shot is, in general, much scattered over the surface of the body. From these results we may form an opinion of the distance at which the piece was fired.

It is difficult to conceive that small-shot can, under any circumstances, produce a single entrance wound, having some appearance of circularity about it, without at the same time singeing or burning the skin or dress. The difficulty of laying down any general rules respecting the wounds produced by small-shot at their entrance and exit, will be apparent from the following facts, communicated to me by two medical gentlemen. A boy was shot in the neck by the accidental discharge of his gun, loaded with an ounce of No. 8 shot. He died instantly. He was leaning forwards on the muzzle, so that it was nearly in contact with the skin of the neck. A large round hole was produced, one inch and a half in diameter, the edges of which were slightly blackened with powder. The exit-aperture, which was at the back of the neck a little to the left of the third cervical vertebra, was a mere slit in the skin, scarcely an inch long, with the long diameter placed vertically. The smallness of this aperture may have been owing to the greater part of the charge being lodged in the body. The entrance-aperture, although rounded, was too large to be mistaken for a bullet wound : it was evidently a near wound, from the blackening of the edges. On the other hand, Dr. Lowe informs me that in some experiments performed by his brother, it was found that a round aperture might be produced by a discharge of small-shot at a much greater distance from the object than that assigned by Dr. Lachèse. Admitting such exceptional instances, and assuming the general correctness of the inferences drawn by Dr. Lachèse, from the results of his experiments in discharging small-shot at dead bodies placed at different distances, it does not seem probable that a wound from small-shot can, under any circumstances, be mistaken for one produced by a leaden *bullet*. A discharge of small-shot, in contact with the skin or close to it, will, however, produce, not a round opening, but a severe lacerated wound.

Small-shot is rarely observed to traverse the body entirely unless discharged so near as to make a clean round opening ; but a single pellet reaching the body may destroy life. There may be no exit-aperture, or it may be smaller than that of entrance. Such minute wounds might be easily overlooked in the examination of a dead body. Small-shot, even

when wounding only the skin of the back superficially, has been known to cause death by tetanus.

Wounds from wadding and gunpowder.—It matters not with what the piece is charged, it is capable, when fired near, of producing a wound which may prove fatal. Thus a gun loaded with wadding, or even with gunpowder only, may cause death. In these cases, an impulsive force is given by the explosion, and the substance becomes a dangerous projectile. The lighter the projectile, the shorter the distance to which it is carried; but when discharged near to the body, it may produce a fatal penetrating wound. A portion of the dress may be carried into the wound, and lead to death from bleeding: or if the wounded person recover from the first effects, he may subsequently sink under an attack of tetanus or erysipelas. It is unfortunate that so much ignorance prevails on this point; for fatal accidents frequently occur from persons discharging guns at others in sport, an act which they think they may perform without danger, because they are not loaded with ball or shot.

It has been observed, that persons in attempting to commit suicide have occasionally forgotten to put a bullet into the pistol; nevertheless, the discharge of a piece into the mouth has sufficed, from the effect of the wadding only, to produce a considerable destruction of parts, and to cause a serious loss of blood. Fatal accidents have frequently taken place from the discharge of wadding from cannon during reviews. It is not easy to say at what distance a weapon thus charged with wadding and powder would cease to produce mischief, since this must depend on the impulsive force given by the powder, and on the size of the piece. Dr. Lachêze ascertained by experiment, that a piece charged with gunpowder, is capable of producing a penetrating wound somewhat resembling that caused by small-shot, when the piece is large, strongly charged, and fired within six inches of the surface of the body. ("Ann. d'Hyg.," 1836, p. 368.) This arises from a portion of the powder always escaping combustion at the time of discharge, and each grain then acts like a pellet of small-shot. Under any circumstances, a discharge of powder only contuses the skin, producing ecchymosis, and often lacerating it, if the piece be fired near. The dress is burnt and the skin scorched from the globe of flame formed by the combustion of the powder; many particles of gunpowder may be actually driven into the true skin. All the substances here spoken of are considered to be projectiles; and the weapons are held in law to be loaded arms, so long as they are capable of producing bodily injury at the distance from which the piece containing them is discharged. It may therefore become a question as to the distance at which these light projectiles cease to be harmless. The answer must be governed by circumstances; but it will in all cases materially depend on the strength of the charge. Dr. Swift, U. S., performed some experiments with a pistol loaded with gunpowder and *wadding*, in order to determine the effect of a discharge at different distances. At twelve inches distance from a dead body, he found that the clothes were lacerated and the skin abraded, but the wadding did not penetrate; at six inches, the clothes were lacerated, and the wadding penetrated to the depth of half an inch; at two inches, the wound produced, which was two inches deep, was ragged and

blackened ; at one inch and a half from the chest, the wadding passed into the cavity between the ribs, and in a second experiment it carried away a portion of a rib. ("Med. Gaz.," vol. 40, p. 734.)

This subject has been investigated by Dr. Mackintosh, of Downham, and he has forwarded to me the results of his experiments. As a summary, he has found, in reference to the wounds produced by wadding, that the amount of injury done is in proportion to the amount of powder in the gun, the hardness and compactness of the wadding or substance used in place of shot or bullet, and the distance of the object from the point of firing. A case occurred in his practice which was the subject of a trial for unlawful wounding. (*Reg. v. Isgate*, Norwich Aut. Ass., 1867.) The prisoner fired at a boy with a gun loaded with brown paper, pressed together. He was then at a distance of two or three yards from the boy. Dr. Mackintosh found a wound in the chest about the size of a shilling. The margin of the wound was jagged, had a bluish-black or mottled appearance, and the edges of one of the ribs was laid bare. The pellet took a course downwards, as a result of its deflection by the rib. A quantity of brown paper was removed from the wound, and the boy ultimately recovered. The question which Dr. Mackintosh proposed to consider was whether paper-wadding could really produce such a wound as was here found, when the gun was fired from a distance of *two or three yards*. Without going into details, it may be stated, that when the gun was charged with a small quantity of powder and brown-paper wadding, there was indentation, but no penetration at a distance of two yards. With one-third more powder and a brown-paper pellet closely compressed, there was penetration through the boy's jacket to an inch and a half beyond. These facts bear out the conclusion already given, and confirmed the boy's account of the distance from which the gun was fired at him by the prisoner. Dr. Swift had inferred from his experiments that a penetrating wound from wadding was not produced unless the piece was discharged within a distance of six inches ; but Dr. Mackintosh's results clearly show that this must depend on the quantity of powder used, and the loose or condensed nature of the substance employed as a projectile.

Identity from the flash of gunpowder.—Among the singular questions which have arisen out of this subject is the following : Whether the person who fires a gun or pistol at another during a dark night can be identified by means of the light produced in the discharge ? This question was first referred to the class of Physical Sciences in France, in 1809, and they answered it in the negative. A case tending to show that their decision was erroneous was subsequently reported by Foderé. A woman positively swore that she saw the face of a person, who fired at another during the night, surrounded by a kind of glory, and that she was thereby enabled to identify the prisoner. This statement was confirmed by the deposition of the wounded party. Desgranges, of Lyons, performed many experiments on this subject, and he concluded that on a dark night, and away from every source of light, the person who fired the gun might be identified within a moderate distance. If the flash was very strong, the smoke very dense, and the distance great, the person firing the piece could not be identified. The question was raised in this

country, in the case of *Reg. v. White*, at the Croydon Autumn Assizes, 1839. A gentleman was shot at while driving home in his gig during a dark night: he was wounded in the elbow. When he observed the flash of the gun, he saw that the piece was levelled towards him, and the light of the flash enabled him to recognize at once the features of the accused. In cross-examination he said he was quite sure he could see the prisoner, and that he was not mistaken as to his identity. The accused was skillfully defended, and he was acquitted. Evidence of this kind has, however, been received in an English court of law. A similar case was tried at the Lewes Lent Assizes, 1862 (*Reg. v. Stapley*). The prisoner shot at the prosecutor, a gamekeeper, on a dark evening in December, and the latter swore that he distinctly saw the prisoner by the flash of the gun, and could identify him by the light on his features. His evidence was corroborated by three other witnesses, who saw him not far from the spot, and by one who saw him in the act of running away. He was convicted. A case is quoted by Paris and Fonblanque (*Rex v. Haines*), in which some police officers were shot at by a highwayman during a dark night. One of the officers stated that he could distinctly see, from the flash of the pistol, that the robber rode a dark-brown horse of a remarkable shape in the head and shoulders, and that he had since identified the horse at a stable in London. He also perceived, by the same flash of light, that the person had on a rough brown great-coat. This evidence was considered to be satisfactory.

From the information which I have been able to collect on this point, it appears to me there can be no doubt that an assailant may be thus occasionally identified. It is widely different, however, in respect to the following case referred to by Müller, in his "Physiology," namely, where a man declared that he recognized a robber through the light produced by a blow on his eye in the dark! As Müller observes, this is a clear impossibility, because the flashes thus perceived are unattended with the emission of light, and therefore can never be visible to any other person than the subject of them, and it is not possible that they can ever make other objects visible. (For some remarks on this subject by Dr. Schilbach, see Henke's "Zeitschrift der S. A.," 1842, 1, 197.) Dr. Krugenstein has lately opposed the inference deduced by Müller, and has supported his views by cases, which, however, do not appear to me to be satisfactory. (Henke's "Zeitschrift der S. A.," 1845, 3, 172.)

Examination of fire-arms.—An attempt has been made by French medical jurists to determine for how long a period a gun or pistol found near a dead body, may have been discharged; but it is out of our power to lay down any precise rules on such a subject. All that we can say is, a quantity of sulphide of potassium, mixed with charcoal, is left adhering to the barrel of the piece, when *recently* discharged; and this is indicated by its forming a strong alkaline solution with water, evolving an odor of sulphuretted hydrogen, and giving a deep-brown precipitate with a solution of acetate of lead. After some hours or days, according to the degree of exposure to air and moisture, the saline residue becomes converted into sulphate of potash, forming a neutral solution with water, and giving a white precipitate with acetate of lead. If a considerable time has elapsed since the piece was discharged, oxide of iron with traces

of sulphate may be found. (See "Ann. d'Hyg.," 1834, p. 458; 1839, p. 197; 1842, p. 368.)

When called to a case of gunshot wound, either accidental or criminal, it is always proper to examine the piece if found. Has it or has it not been recently discharged, may be a material question. A trial took place on the Western Circuit, March, 1873, in which the fact was of great importance. The prisoner asserted that his gun had not been used for a long time. On examination of the barrel, however, it was found to have been quite recently discharged. This at once connected him with the act of wounding of which he was accused. In an agrarian murder in Ireland, in October, 1876, there was found imbedded in the heart of deceased the half of a common marble, such as children use in play. A bag of marbles, of the same size and kind, was found in the house of one of the prisoners, and this discovery connected him with the act.

The examination of wadding or paper found in a gunshot wound or near a dead body, has, in more than one instance, led to the detection of the person who had committed a crime. His handwriting has been traced on the paper used as wadding, or it has been found to have been part of a printed page, of which the remainder has been discovered in his possession. When a gun is discharged near to the body, a portion of the wadding is generally carried into the large irregular wound which is produced. This was part of the evidence in the case of *Reg. v. Blagg* (Chester Summer Ass., 1857). The peculiar character of the wadding found in the body connected the prisoner with the act. Whether the wadding is found in or near the body, it should be equally preserved. In *Reg. v. Richardson* (Lincoln Ass., Dec. 1860), the accused was convicted of murdering a policeman under the following circumstances: He shot at the deceased, who was able before death to identify the prisoner; but as the deceased was weak from loss of blood and failing in consciousness at the time, there was some difficulty in relying upon this dying declaration, especially as no other person witnessed the act. Some paper-wadding had been picked up on the spot where the deceased fell; and a gun which had one barrel loaded, and one empty from a recent discharge, was found in the prisoner's house within twenty-four hours of the murder. The wadding in the loaded barrel consisted of a fragment of "The Times" newspaper of the 27th of March, 1854, and the charred and sulphurous pieces of wadding picked up on the spot were proved by the publisher of that journal, who was summoned on the trial, to have formed a portion of the same impression. The prisoner's counsel, in fact, though he contended with marked ability for the innocence of the prisoner, could not deny that the act had been brought home to the instrument if not to the agent, and though the explanation of the crime remained obscure to the last, and the motive unassignable, the aggregate evidence proved sufficient to convince the jury. Any projectiles found in a gunshot wound should always be preserved for evidence. In the case of *Rush*, who was tried and convicted of the murder of *Mr. Jermy*, by a remarkable train of circumstantial evidence (Norwich Lent Ass., 1849), it was proved that the projectiles removed from the body of the deceased consisted of irregular pieces of lead (slugs). Similar masses were taken

from the body of the son, who was killed at the same time. They were described by the medical witness as being angular, and quite unlike the shot used in killing game. This proved that the two acts of murder were committed by the same person, or by this person acting in concert with others.

The chemical analysis of a projectile may be occasionally necessary. A common bullet is formed entirely of lead. Cast bullets are commonly found to have a void space in the interior when cut through the centre, owing to the exterior cooling more rapidly than the interior, and to the greater bulk of the metal when in a liquid state. In large bullets this cavity is frequently of the size of a barleycorn. Bullets obtained by compression have no such space, and are of greater specific gravity. Small shot is composed of lead, with a minute fractional portion of arsenic ($\frac{1}{250}$ th part). If the arsenic is in large proportion the shot is lenticular; if absent or in small proportion, pyriform (Ure). In the case of *Rush*, type-metal was found in the house. This consists of lead with one-fourth part of antimony, the latter being left by digestion in nitric acid. It was therefore considered advisable to examine the slugs chemically, and they were found to consist chiefly of lead, and to contain no antimony. The type-metal was thus excluded.

CHAPTER XXXVII.

DEATH FROM BURNS AND SCALDS.—SYMPTOMS.—STUPOR.—CAUSE OF DEATH.—POST-MORTEM APPEARANCES.—BURNS ON THE DEAD BODY.—ACCIDENT, HOMICIDE, OR SUICIDE.—WOUNDS CAUSED BY FIRE.—SCALDING.—BURNS BY CORROSIVE LIQUIDS.

Burns and scalds.—A *burn* is an injury produced by the application of a heated substance to the surface of the body; while a *scald* results from the application of a liquid at or near its boiling point, under the same circumstances. There seems to be no real distinction between a burn and a scald in reference to the effects produced on the body; the injury resulting from boiling mercury or melted lead might take either appellation. Nevertheless, as a matter of medical evidence, it may be important to state whether the injury found on a body was caused by such a liquid as boiling water, or by a heated solid. If the former, the injury might be ascribed to accident; if the latter, to criminal design. A scald produced by boiling water would be indicated by a sodden state of the skin and flesh, but there would be no destruction of substance. In a burn by a heated solid, the parts may be more or less destroyed, or even charred; the cuticle may be found blackened, dry, almost of a horny consistency, and presenting a shrivelled appearance. This distinction, however, would only apply to scalds from water. A scald from melted lead (620°) could not be distinguished from a burn produced by a solid heated to the same temperature. Some of the oils boil at 500° ,

and they produce, by contact with the skin, burns as severe as those caused by melted metal. Burns from flame, such as that of gas, are indicated by extensive scorching of the skin, while burns from gunpowder are known not only by the scorching, but by the small particles of unburnt carbon which are imbedded in the skin.

Neither a burn nor a scald appears to be considered as a *wound* in law; but in the statute of wounding they are included among bodily injuries dangerous to life. Burns and scalds may be regarded as dangerous in proportion to the extent of surface (of skin) which they cover, as well as the depth to which they extend. The extent of skin involved in a superficial burn, as a result of exposure to flame, is of greater importance than the entire destruction of a small part of the body through an intensely heated solid. When the burn is extensive, death may ensue either from the severity of the pain produced, or from a sympathetic shock to the nervous system. Death takes place rapidly from burns in children and nervous females; but in adults and old persons there is a better chance of recovery. In some instances, especially in children, stupor and insensibility supervene, owing to the sympathy of the skin with the brain; and these symptoms have been soon followed by coma and death. If, under these circumstances, opium has been given to the patient as a sedative, the stupor resulting from a burn may be attributed to the narcotic effects of the drug; and should the person die, the practitioner may find himself involved in a charge of malapraxis or manslaughter. It may be alleged, as in the following case which occurred to Mr. Abernethy, that the person was poisoned by opium. A medical man was charged with the manslaughter of a child, by giving to it an overdose of opium while it was laboring under the effects of a severe scald. Mr. Abernethy stated in his evidence, which was given in favor of the practitioner, that he thought the use of opium was very proper; that the quantity given, eight drops of tincture of opium immediately after the accident, and ten drops two hours afterwards, was not an overdose for a child (the age is not stated). The circumstance of the child continuing to sleep until it died, after taking the opium, was, in his judgment, no proof that it had been poisoned. The sleep was nothing more than the torpor into which it had been plunged by the accident. The surgeon was acquitted. Notwithstanding the very favorable opinion expressed by Mr. Abernethy of this plan of treatment, it would be advisable to avoid the use of opium on these occasions in treating infants and children. Life is readily destroyed in young subjects by the smallest doses of this drug; and there are no satisfactory means of distinguishing the comatose symptoms produced by a burn or a scald from those produced by an overdose of opium (p. 200).

Cause of death.—In some instances, especially in children, stupor and insensibility have rapidly supervened, owing to sympathy with the brain; and these symptoms have been followed by coma and death. Of the cause of death in persons exposed to fire but little need be said. In large conflagrations persons are frequently simply suffocated, from the want of a proper amount of air or from breathing the products of combustion—carbonic acid or carbonic oxide. The former darkens the blood and muscles; the latter renders them lighter in color. In other cases, where

a large volume of flame suddenly falls upon the body and the person is still able to breathe, the fatal effect may be due to shock—a sudden and violent impression on the nervous system through the skin. A person may recover from the first effects of severe burns, but ultimately sink from exhaustion or from an attack of tetanus. ("Med. Times and Gaz.," April, 26, 1854, p. 406. See "Ann. d'Hyg.," 1873, vol. 1, p. 232.) The annual deaths from burns and scalds are numerous. According to a return of the Registrar-General for 1871, there were in England and Wales 2612 deaths from this cause.

Post-mortem appearances.—In examining the body of a person found burnt, all matters connected with sex and identity should be first duly observed. Dr. Grunbaum has reported a case in which he was required to examine certain carbonized remains in which, in spite of the destruction of the sexual organs, he was able to determine the sex. (Horn's "Vierteljahrsschrift," Oct. 1864.) When a body has been entirely consumed by fire the presence of a large quantity of phosphate of lime in the ashes would indicate animal remains. The bones are never completely destroyed; they become white, and the mineral portions of them retain their form even after the action of a most intense fire.

When death has been caused by severe pain, no changes have been detected in the dead body; but, in some fatal cases, it has been found on inspection that there were patches of redness on the bronchial mucous membrane, as well as in the stomach and intestines. The brain has been found gorged, and the ventricles have contained an abundance of serosity. The serous liquids of the pericardium and pleura have also been in larger quantity than natural. In short, besides congestion, there is generally abundant serous effusion in one of the three great cavities, especially in the head. This arises from the sudden reflux of blood into the interior, as an effect of the local injury. In deaths from fires in houses, the persons are usually suffocated, and then there are the appearances of this kind of death (see SUFFOCATION). In a case in which a woman died on the thirteenth day from a superficial burn involving the skin of the lower part of her body, the stomach was found inflamed at its greater extremity, and the duodenum at its lower portion—the mucous folds of the intestines having a scarlet color. The other intestines as far as the cæcum were also more or less inflamed. ("Amer. Jour. Med. Sciences," Jan. 1861, p. 137.) If the person survive the first effects, he may die from inflammation, suppuration, gangrene, irritation, or fever, or he may be worn out by exhaustion.

Did the burning of the body take place before or after death?—Vesication.—The production of *vesication* or of *blisters* containing serum, is commonly regarded as an essential character of a burn which has been produced during life, but it is not a necessary or invariable effect of a burn on the living body. Vesication is especially observed in scalds, or in those cases in which the skin has been burnt by flame or by the ignition of the clothes, provided the cuticle has not been destroyed. It is not so commonly observed in burns produced by intensely heated solids. In vesication, the cuticle is raised from the true skin beneath, and is converted into one or more blisters containing serum or a serous liquid, while the skin around is of a deep-red color. It is uncertain as to the

time at which it appears ; it may be produced in a *few minutes*, or sometimes not for several hours ; hence death may take place before vesication occurs, and the non-discovery of this condition does not warrant the opinion that the burn could not have taken place during life. If the cuticle is removed from a vesicated part of the living body, the skin beneath will become intensely reddened, but if the cuticle is stripped off a dead body, the skin will become hard, dry, and of a horny-yellow color ; it does not acquire the intense scarlet injection which is required by the living skin when vesicated and the surface is exposed.

In cases in which persons, while living, have suffered from general dropsy, it has been found, on the application of heat to their bodies after death, that blisters containing serum or a serous liquid have been formed ; hence, in drawing a conclusion from the examination of *burns* on the body of a person affected with general dropsy, it is necessary to be cautious. In such cases it would not be possible, from the mere presence of serous blisters, to say whether the burn was produced before or after death. The late Dr. Wright found in his experiments on the dead body, that if a sufficient heat were closely applied to the skin within half an hour or longer after death, blisters containing serum were sooner or later produced. In short, as long as the body was warm and the joints were flexible, the effects of fire were similar to those observed on the living. Other experimentalists have found that blisters were produced, but that they did not contain serum. The result no doubt depends on the time after death at which the experiment is performed.

Accident has enabled me to describe the results produced on the skin of a healthy adult within a very short period after death. The body of a drowned man, within a few minutes after the accident, was removed from the water and placed in a warm (hot ?) bath. It was found impossible to resuscitate him, but owing to the great heat of the water, portions of the cuticle came off, when the body was removed. On inspection there were several vesications *filled with bloody serum* over a considerable portion of the skin, especially of the extremities. There was no anasarca here to account for their production ; and the fact of their occurrence appears to bear out the view of Dr. Wright, that the production of a *serous* blister on a dead body depends on the amount of latent organic life remaining in it. In this case the man was pulseless and to all appearance *dead*, when placed in the hot bath ; hence the effects of hot water on the living and recently dead body, so far as the production of serous blisters is concerned, are similar. Dr. Chambert has lately published the results of numerous experiments on the effects of burns on the living and dead body. These have been made on the bodies of persons from the moment of death until twenty hours after dissolution, and some were performed before death. The general results of his researches are, that vesications, or blisters, may be produced by burns both on the living and dead body ; that they are produced at a lower temperature in the living than in the dead ; that in the living a burn produces great capillary congestion, with the effusion of serum in the blisters, and that this serum when heated, or treated with nitric acid, sets into a nearly solid coagulum. The blisters produced in a dead body, even a few minutes after death, contain a thin watery serum which is only rendered

determined from its appearance, how long a period it would require to produce the amount of destruction observed. Such a question may arise when it is intended to connect a person with the perpetration of an alleged crime, but it does not admit of a precise answer. A conjecture only can be formed from the facts proved in each particular case. The human body contains a large proportion of water (72 per cent.); this gives to the soft structures a power of resisting combustion. At the same time there is a quantity of fat in the body, varying in different parts, but amounting to an average of about five per cent. The fat or oil tends to increase its combustibility, and this is still further increased if the body is placed on any combustible article which can imbibe the oil, such as a rug or a deal floor. The nature of the dress will also make a difference. Under a strong and active flame, which might subsequently burn out before the discovery of the body, there would be a degree of destruction in half an hour, which a more slow and smothered combustion would not effect in several hours. It is from a want of due consideration of these facts that some of the older medico-legal writers have given support to the hypothesis of *spontaneous combustion*. It has been supposed that in certain cases the dead human body has been destroyed more than appeared consistent with the fact of ordinary combustion from articles of dress or furniture; but this opinion has arisen from a want of sufficient experience on the effects of heat. Then, as the means by which the dress of a person had become ignited were generally destroyed with the body, it was thought that a human being might, under certain conditions, be consumed by fire spontaneously generated within him. This extravagant hypothesis, which is on a par with the belief in witchcraft, and requires an equal amount of credulity to receive it, has, however, found advocates in modern times. In March, 1850, a man named *Stauff* was tried at Darmstadt, for the murder of the *Countess of Goerlitz*. He had assaulted the deceased in her chamber, and then set fire to the furniture with a view to conceal his crime. The body and dress were partially consumed. As the means by which the fire was applied were not at once apparent, and the assassin had locked the doors of the room, some medical men took up the theory that the deceased had died from spontaneous combustion.

The facts of the case were referred to Professors Liebig and Bischoff, of Giessen; and their report was issued in March, 1850, at which date the man *Stauff* was put on his trial. They found no difficulty in concluding that a murder had been perpetrated, and the body wilfully burnt *after death* for the purpose of concealing the crime. There was some doubt whether the deceased had died from strangulation, or from violence to the head. *Stauff* was convicted chiefly on circumstantial evidence. He subsequently confessed that the Countess had entered her room as he was in the act of committing a robbery. A struggle took place; he seized her by the throat, strangled her, and afterwards placed the body in a chair, piling around it combustible articles of furniture. He set fire to these with the view of destroying the proofs of his crime. It was observed that the tongue of the deceased was protruded, as it is in violent strangulation, and that in its charred state it retained the position given to it by the act of murder. Other instances of alleged sponta-

neous combustion, if properly investigated, would have turned out to be cases of accidental or homicidal burning.

Spontaneous combustion may take place in some kinds of vegetable and mineral substances, but not in the animal body, living or dead.

Amongst the questions which arise in reference to a body found dead from *burns* is this: Whether the burns have been caused by gas, by inflammable vapors, such as petroleum, or by gunpowder. Petroleum is at once indicated by its peculiar and powerful odor, and the sooty blackening of the parts burnt. In *Reg. v. Gaitskell* (Carlisle Spring Ass., 1872), prisoner was convicted of manslaughter under the following circumstances: He poured a quantity of petroleum over the clothes of the deceased, and by accident the vapor caught fire, and the burns produced caused the man's death on the following day. Burns from petroleum, paraffine, kerosine, or any form of rock oil, are generally of a severe kind. The clothes of a person readily imbibe the liquid, and by their fibrous structure act as a wick for spreading the combustion. There have been several cases in which men have been convicted of the murder of their wives by throwing at them a lamp in which petroleum was burning. The ignition of the dress has led to rapid death. Burns from the flame of gunpowder are generally characterized by blackening of the skin, and the introduction of some of the grains into the substance of the skin, producing the effects of tattooing.

Corrosive liquids.—Among the cases in which medical evidence is sometimes required, are those of throwing mineral acids, alkalies, or other corrosive liquids on the person. This crime was at one time prevalent, and until an alteration was made in the criminal law there was no adequate punishment for it (24 & 25 Vict., c. 100, s. 29). On one occasion, an assailant escaped a charge of felony, because it could not be considered, in law, that sulphuric acid was capable of producing a *wound*—the man having been indicted for wounding! This case clearly showed a strong necessity for some legal definition of a wound, as well as the uncertainty of medical opinions; for while one surgeon considered that the injury produced was a wound, another thought that it was not. The judges decided that it was not a wound within the meaning of the Act. The statute above mentioned, while it punishes the offence, omits all reference to a definition of the word wound. The nature of the liquid thrown is merely defined in general terms, to be “any corrosive fluid or any destructive substance”—a point which will require medical evidence for its elucidation.

In common language, and according to the statute, the injury thus produced by a mineral acid such as oil of vitriol, is called a burn, but it is wholly different in its origin, as well as in its progress. I do not know that there has been a single instance in which such an injury has directly destroyed life; but great deformity and actual blindness have resulted. A medical man is sometimes required to distinguish these injuries from burns and scalds; this may be easily done, in the first instance, by the appearance of the part injured, as well as by the description of the first symptoms. The stain is brown when sulphuric acid has been used, and yellow when nitric or hydrochloric acid has been employed. The eschar or destroyed part is soft, and not dry as in a burn from a heated solid. The skin touched by a concentrated acid is destroyed and sloughs away,

to the extent of the part on which the corrosive liquid was applied, leaving a suppurating and granulating surface. There is no capillary congestion or redness of the skin around the injury as in a burn; but the color of the injured part may throw some light upon the nature of the corrosive substance used. Thus, while oil of vitriol (sulphuric acid) produces dark-brown stains, aquafortis (nitric acid) produces yellow or yellow-brown stains on the skin. Articles of dress are also differently colored by these acids. The period at which a person may recover from an injury of this kind depends on its degree and extent, as well as on the part affected by the corrosive liquid. Although a person may not die from the direct effects of the acid, yet in certain irritable constitutions the inflammation which follows in deep-seated parts may prove fatal. In infants, or delicate nervous females, an extensive injury thus produced, may readily destroy life. In one instance, sulphuric acid thrown on the face produced inflammation of the eye, for which bleeding was prescribed. The person died of phlebitis (inflammation of the vein), as the result of this bleeding.

The nature of the acid may be determined by applying wetted linen to the part, when the injury is recent, and examining the liquid thus absorbed. In general, however, evidence is readily obtained by examining the spots or stains left on articles of clothing or furniture. Oil of vitriol is most commonly used. The caustic alkalis may be used under these circumstances, as well as numerous other liquids, on which the only medical opinion required would be, whether the article employed should or should not be considered as a "corrosive" liquid or a "destructive" substance. To constitute a felony, it is not now necessary that the *person* should have sustained any bodily injury from the act of throwing the corrosive liquid. Unless vital reaction has taken place, there are no means of distinguishing the effects of a corrosive liquid on the living from those produced on the dead body. ("Ann. d'Hyg.," 1859, vol. 1, p. 396.)

The mineral acids are sometimes used in other ways for the destruction of life. In June, 1833, a man poured a quantity of strong nitric acid into the ear of his wife while she was lying asleep. She awoke suddenly with a violent pain in the ear, which continued for three days, whereby she became weak and exhausted. Soon afterwards there was copious bleeding, and a portion of membrane escaped. She lost the use of her right arm, and became completely deaf. Suppuration took place from the ear, and blood escaped daily. She gradually sank, and died six weeks after the injury, the right half of the body being convulsed before death. On inspection, a portion of the external ear was wanting, and the ear-passage was much wider than natural. The brain, near the petrous portion of the temporal bone, was softened, and the bone itself diseased (carious). The injury had led to death indirectly by producing disease of the brain. ("Med. Gaz.," vol. 17, p. 89.)

In a case tried at Aberdeen, the evidence proved that a woman had poured oil of vitriol down the throat of her husband, while he was lying asleep with his mouth open. She was convicted of the murder. In a more recent case, a woman killed her husband by pouring a solution of corrosive-sublimate down his throat while he was sleeping. These, however, were treated as cases of poisoning, as death did not depend on the local or *external* mischief produced by the corrosive agent employed.

ASPHYXIA.

DROWNING.

CHAPTER XXXVIII.

CAUSE OF DEATH.—SECONDARY CAUSES.—POST-MORTEM APPEARANCES.—
 MEDICAL PROOFS OF DEATH FROM DROWNING.—SPECIFIC GRAVITY OF
 THE BODY.—CO-INCIDENTAL CAUSES OF DEATH.—MARKS OF VIOLENCE.
 —ACCIDENTAL FRACTURES.—HOMICIDAL AND SUICIDAL DROWNING.

UNDER the term *Asphyxia* or *Apnoea* are included those forms of violent death in which the act of respiration is primarily arrested (p. 59). These comprise death from drowning, hanging, strangulation, and suffocation; and in this section the fatal effects of lightning, cold, and starvation will be considered.

The subject of asphyxia and the appearances presented by the body in this mode of death, have already been fully considered. In addition to what has been stated, it may be observed that Professor Gwosdew, of Moscow, has described as a diagnostic sign of asphyxia in the dead body, the presence in the blood (when submitted to spectral analysis) of a single broad absorption-band corresponding to reduced hæmoglobin, in place of the two well-known absorption-bands of oxy-hæmoglobin. But it has been found by Hoffmann and others that this state of the blood is common to all kinds of death, as the tissues exert a reducing action upon it. When air has had access to the blood after removal from the body, the two ordinary absorption-bands are seen. Spectral analysis, therefore, affords no clue to the mode of death.

Drowning.—Cause of death.—Asphyxia.—In drowning asphyxia is produced by a physical impediment to the introduction of air into the lungs. The medium in which the person is immersed acts mechanically, and even more effectually than a rope or ligature round the neck; for although air escapes from the lungs, and water penetrates into the minute air-tubes, yet no air can enter to supply the place of that which has already expended its oxygen on the blood. Hence this fluid must circulate, in the first few minutes after submersion, in a state unfitted for the support of life (unaërated); but the person lives, and is susceptible of recovery within a short interval. After the entire suspension of respiration, the action of the heart gradually slackens, and finally stops.

It is at this period of the arrest of circulation that asphyxia passes into death. Asphyxia is determined by the period at which respiration is completely arrested; but the point of time at which death from drowning occurs is fixed by the moment at which the action of the heart ceases. This varies considerably, according to age, sex, state of health and other circumstances.

When a person falls into water, and retains his consciousness, violent attempts are made to breathe: at each time that he rises to the surface a portion of air is received into the lungs, but, owing to the mouth being on a level with the liquid, water also enters and passes into the throat. A quantity of water thus usually enters the mouth, which the drowning person is irresistibly compelled to swallow. In his efforts to breathe while his head is below water, a portion of this liquid is drawn into the air-tubes and cells of the lungs. The struggle for life may continue for a longer or shorter period, according to the age, sex, and strength of the person; but the result is that the blood in the lungs is imperfectly aerated, the person becomes exhausted, and insensibility follows. The mouth then sinks altogether below the level of the water—air can no longer enter into the lungs; a portion of that which they contain is expelled, and rises in bubbles to the surface; an indescribable feeling of delirium, with a ringing sensation in the ears, supervenes: the person loses all consciousness, and sinks asphyxiated. In the state of asphyxia, while the dark-colored blood is circulated, convulsive movements of the body take place, and the contents of the stomach are sometimes ejected by vomiting. There does not appear to be any sensation of pain, and, as in other cases of asphyxia, if the person recovers, there is a total unconsciousness of suffering during the period when the access of air was cut off from the lungs.

Some persons who fall into water are observed to sink at once, without making any attempt to extricate themselves. This may arise either from sudden syncope or from the stunning produced by the fall. Should the person be intoxicated or otherwise incapacitated, as by striking his head in falling, he may not again rise. These different conditions under which death may take place, will sufficiently account for the difference in the appearances met with in the bodies of those who have died in water. A fatal result may be accelerated by the impression suddenly produced upon the skin, from the difference of temperature between the body and the water. To those who are not accustomed to water, a sudden immersion produces a great and rapid cooling of the surface, and forces the blood into the internal organs. There is difficulty of breathing, or severe spasmodic respiration, with giddiness and other symptoms, which may render a person powerless to extricate himself. The effect of cold on the skin is seen in the contracted state of the cutis in the bodies of those who have been drowned during the winter. It is calculated that in 25 per cent. of all who are drowned, the cause of death is pure asphyxia, and that in the remainder, syncope and cerebral congestion amounting to apoplexy, may have a share in causing death.

In regard to the time required for death to take place by drowning, it may be observed that when the mouth is so covered by water that air cannot enter, asphyxia comes on in the course of one or two minutes at

the farthest, and the time at which this occurs does not appear to vary materially. Perfect insensibility has supervened after one minute's submersion, and it is probable that in most cases a few seconds would suffice for the commencement of asphyxia. In this state a person can make no efforts to save himself, and death commonly ensues in from *two to five minutes*. The power of restoring life depends not merely on the time that the body may have been submerged, but on the condition of the lungs at the time of its removal from the water. Experiments performed by a Committee of the Medico-Chirurgical Society have clearly proved that, as a form of asphyxia, drowning is not only more speedily fatal to life than ordinary suffocation, but, from the physical changes produced in the lungs by water, the chances of recovery are lessened.

The committee found that the difference in the results was not owing to exhaustion from struggling, from the violent efforts made to breathe, or from the effects of cold in immersing the whole of the body, but to the introduction of water by aspiration into the minute air-tubes and cells of the lungs. This conclusion was derived from the following experiments: Two dogs of the same size were submerged at the same moment, but one had his windpipe plugged, so that no air or water could enter, while the other had not. After *two minutes* they were taken out together; the one with the windpipe plugged recovered at once, the other died. In three experiments, dogs with their windpipes plugged were kept below water for *four minutes*: the animals recovered perfectly when removed from the water. (Report on Suspended Animation, "Med.-Chir. Trans.," 1862, p. 449.) An inspection of the bodies at once revealed the difference. In animals simply deprived of air by plugging the windpipe, the lungs were merely congested; but in those which were submerged in their ordinary condition, the lungs, besides being more congested, and showing ecchymosed points on the surface and in the substance, contained in their bronchial tubes a bloody mucous froth, formed of water, blood and mucus, which completely filled the small air-tubes. The violent respiratory efforts made by the animal before death had caused the production of this froth, which formed a mechanical impediment to the entrance of air by the movements of the chest, as in respiration. This mucous froth or foam issued from the lungs on section, and appeared to penetrate their entire substance, which was saturated with water tinged with blood. The lungs were sodden with water, heavy, soft, doughy, retained an impression produced by the finger, and were incapable of collapsing. In the lungs of animals which recovered after a short submersion, little or none of this mucous froth was found in the air-cells. In the fatal cases, the quantity was great in proportion to the time of submersion. There is no doubt that this froth is produced by the violent efforts to breathe, which are made within a minute after submersion.

It may be inferred from these results that the power of recovery in human beings has a direct relation to the quantity of mucous froth in the air-tubes, and to the penetration of the substance of the lungs with water. The larger the amount of froth produced, and the greater the penetration, the less the hope of recovery; for when the lungs have un-

dergone these changes they are physically unfitted either to receive or expel air by respiration—they are incapable of collapsing. These circumstances will account for the fact that persons have been resuscitated in drowning under various and even opposite modes of treatment, and even under no treatment at all. It is right that every reasonable effort should be made to restore life; but if the lungs are sodden with water, their functions cannot be restored by any mode of treatment. The committee found that a complete submersion of *four minutes* effectually killed dogs, although after removal from water the heart continued to beat from four to five minutes. The continuance of the heart's action furnishes, therefore, no criterion of the power of recovery. A human being, as a rule, dies if submerged for a period of from four to five minutes. In a few exceptional cases, persons have been resuscitated after this period, but it is most probable that in them the lungs had sustained no physical damage. Considering the kind of treatment to which the bodies of the drowned have been in some instances submitted; there is much truth in the observation of the late Sir B. Brodie—namely, that recovery has often followed not from the means used, but in spite of them! When the submersion has been short, the respiratory struggles below water slight, and the person has been treated immediately on removal, recovery is probable; but under opposite conditions, it is, with rare exceptions, hopeless.

Treatment.—The facts above mentioned have a close relation to the treatment of the drowned. The subject is hardly of a medico-legal nature, but occasionally questions have arisen at coroners' inquests in reference to the propriety of the treatment adopted by a medical practitioner. When it is stated that conflicting methods have been apparently equally successful, it will be perceived that there is great difficulty in making a selection or laying down rules. Artificial inflation of the lungs appears *à priori* to be the proper plan for resuscitation. The late Dr. Woolley, who had considerable experience in treating the drowned, informed me that, as a rule, he had seen no benefit from the introduction of air by artificial processes (see "Med. Gaz.," vol. 17, p. 663), and that the warm bath (at 106°), with frictions to the skin, had been in his hands the most successful means of treatment. When some signs of animation were not elicited by the warm bath, there was but little hope of any other plan succeeding. Artificial inflation in some form is now, however, generally employed, in addition to the application of warmth and stimulating frictions to the skin. The committee of the Medico-Chirurgical Society, discarding the use of apparatus which is rarely at hand when most required, recommends the method of inflating the lungs suggested by Dr. Sylvester, "in which the action of the pectoral and other muscles passing from the shoulders to the parietes of the chest in deep inspiration, is imitated." This plan has been adopted by the Royal Humane Society. The committee have demonstrated by experiment that it is superior to the method recommended by the late Dr. Marshall Hall, inasmuch as it commences with the act of inspiration, while the latter begins with expiration, and it more completely fills and empties the air-cells of the lungs: 1. Remove from the neck and chest all articles of clothing; 2. Wipe the body dry, and cover it with dry cloths; 3. Clear the nostrils, mouth,

and throat of all mucous froth, or of substances likely to interfere with free respiration: pull forward the tongue, and keep it in this position so that it may not fall back and cover the opening of the windpipe; 4. Place the body at full length with the face downwards, the forehead resting on one arm; this is for the purpose of allowing all fluids to flow readily out of the mouth; 5. Ammonia, aromatic vinegar, snuff, or other stimulants, may be cautiously applied to the nostrils; and 6. If respiration is not quickly restored spontaneously, then the body should be placed upon its back, with the head slightly raised. The arms should be gently carried outwards and upwards from the chest, raised above the head, and maintained in this position for about two seconds. By this movement air penetrates into the lungs as during the act of inspiration. The arms are now lowered and brought closely to the sides of the chest, by which expiration is effected. Pressure on the lower part of the chest-bone (sternum) aids this expiratory action. This movement should also occupy two seconds. These alternate movements of the arms may be repeated from twelve to fourteen times in a minute. All rough handling should be avoided. So soon as any spontaneous respiratory action is observed, warmth may be applied to the skin by the warm bath or otherwise, and stimulating frictions may be used, or simple frictions with warm flannels, etc. Heat should be implied especially to the region of the heart, the loins, soles of the feet, and palms of the hands. When the power of swallowing returns, warm water alone or with a little brandy as a stimulant, may be given. The patient should then be placed in bed and allowed to sleep.

This treatment should be persisted in for some hours, except in those cases in which the body has been long under water, and is taken out cold and rigid. In Dr. Douglas's case there were no signs of returning animation until after the treatment had been carried on for eight and a half hours. The tendency to restoration is indicated by the occurrence of slight flushing in the face, with convulsive twitchings in the facial muscles, warmth of the skin, grasping or sobbing respiration at intervals, and sometimes convulsive movements of the body and limbs. The unfavorable signs are: complete insensibility, coldness, and paleness of the body; no spontaneous act of respiration; entire absence of pulsation in the region of the heart; the eyelids half-closed, the pupils dilated, the lower jaw stiff, the fingers half bent inwards, and the mouth and nostrils containing mucous froth, which is continually escaping from them. The chances of recovery are great in proportion to the shortness of the interval between the last expiratory efforts in the state of asphyxia and exposure to the air. In a very large proportion of all cases of recovery after submersion, the act of respiration in the form of sobbing, sighing, or gasping commences spontaneously soon after the person has reached the air, and the only treatment then required is not to interfere with this natural action of the chest.

Death from secondary causes.—Drowning may operate indirectly as the cause of death. Thus it has been repeatedly remarked that persons who have been rescued from water in a living state, and who have apparently recovered from the effects of submersion, have died, in spite of treatment, after the lapse of some minutes or hours; others have lingered

for one or two days, and then have sunk apparently from exhaustion. In those who perish soon after removal from water, death may arise either from exhaustion, or from the obstruction of respiration by the penetration of water into the air-cells of the lungs. The case of *Colonel Mackenzie* (Aug. 1873) furnishes an instance of rapid death from secondary causes. The colonel and a companion, while crossing a river, were carried away by the current. After much struggling, they both reached the bank in an exhausted state. The companion left the colonel apparently well, to procure assistance. On his return soon afterwards, the colonel was found dead. Death was attributed to apoplexy, but it was more probably due to exhaustion from over-exertion. A child, *æt.* 2½ years, was found floating on water. It was insensible, with gasping breathing, heart fluttering, no pulse at the wrists, tongue protruded and cold, water draining from the mouth and nose. Artificial respiration restored breathing, but not sensibility. Convulsions followed, lasting two hours. These passed off. The breathing was natural and the body warm: temperature 101.2°. In this state the child continued seven hours, when difficulty of breathing suddenly came on, and the child died eighteen or twenty hours after removal from the water. (*Indian Report*, by Mr. Richards, of Goalundo.) Dr. Marcet states that spasm of the glottis has been among the severe secondary symptoms in persons who have been removed from water, apparently drowned. A severe spasm of this kind manifested itself in one case while placing the patient in a warm bath. ("Med. Times and Gazette," February, 1857, p. 148.) When death takes place at a remote period, it may be caused by disease; and a question may thence arise, whether the disease was produced by the immersion in water, or not. Such cases occasionally present themselves before our Courts of Assize.

Post-mortem appearances.—The external and internal appearances produced by drowning, vary according to the length of time during which the body may have remained in water, and the period that may have elapsed after its removal and before it is examined. Thus, in reference to the bodies of two persons drowned by a common accident, if one is removed and examined immediately, and the other is not removed from the water until after the lapse of several days, and is then inspected, the appearances will be different. So, if the two bodies are removed at the same time, and one is immediately examined, while the other is not inspected until a month after removal, the proofs of drowning which may be discoverable in the former will probably have disappeared in the latter. A protracted exposure of the drowned body either to water or air, especially if the temperature is high, renders an inspection useless for the purpose of evidence.

External appearances.—Supposing that the body has remained in the water only a few hours after death, and the inspection has taken place immediately on its removal, the *skin* will be found cold and pallid—sometimes contracted, under the form of "*cutis anserina*." This contracted state of the skin, when found, furnishes strong evidence of the body having gone into the water living. The skin is often covered to a greater or less extent by livid discolorations; the face is pale and calm, with a placid expression; the eyes are half open, the eyelids livid, and

the pupils dilated; the mouth closed or half open, the tongue swollen and congested—frequently pushed forwards to the inner surface of the lips, sometimes indented or even lacerated by the teeth; and the lips, together with the nostrils, are covered with a mucous froth which issues from them. Kanzler has noticed in the male subject a remarkable retraction of the penis. In men who have gone living into the water and been drowned, this appearance has been repeatedly observed by Casper and Kanzler; and the former states that he has not met with this condition of the male organ after any other form of death. In strong and robust men it has been found short, and strongly retracted into the skin. (“Ger. Leich.-Oeffn.,” ii. 109.) The body and limbs of a person recently drowned are usually found relaxed; but cadaveric rigidity appears to come on quickly in cases of drowning, and the body is often stiffened in the convulsed or distorted attitude which it may have had at the time of death. In a case observed by Mr. Beardsley, the body of a man who was drowned under ice, was found with the arms stiffened in the attitude in which he was endeavoring to support himself on the ice.

Among the casual external appearances, it has been noticed that the fingers and surface of the body occasionally present *abrasions*. Gravel, sand, mud, weeds, or other substances, may be found locked within the hands or nails of drowned persons; for in the act of drowning, as common experience testifies, a person will grasp at any object within his reach, and in his efforts to extricate himself he may excoriate or wound his fingers. Substances floating in the water are also sometimes found in the nose, mouth, and ears. There are, however, many cases of drowning in which such appearances do not exist. There may be no substance for the drowning person to grasp; this will depend in a great degree upon the fact of the water being deep or shallow, of its being confined within a narrow channel or not, and many other contingencies. In all cases, when the person is senseless before he falls into the water, or when his death is occasioned by syncope, he will, of course, be incapable of making those exertions which are necessary to the production of this appearance, and it is probable that this frequently occurs among women who are accidentally drowned. When the body has remained several days in water, the skin of the palms of the hands and soles of the feet is found thickened, white, and sodden, as a result of imbibition.

Internal appearances.—In a recently drowned body, the lungs and heart present the appearances usually indicative of asphyxia (p. 59, *ante*). The venous system is generally gorged with dark-colored liquid blood. If death has not taken place from asphyxia, or if the body has remained a long time in water before an inspection is made, the lungs and heart will not present the characters about to be described. Some physiologists have asserted that the *blood* remains fluid in the bodies of the drowned; but more importance has been attached to this appearance than it really merits. Some observers have found the blood coagulated in the drowned, and I have seen coagula, like those usually met with after death, in the bodies of animals which were drowned for the sake of experiment. If the blood is found generally liquid, this may be due to the imbibition of water, or to putrefactive changes. Riedell found the

blood in the heart and large vessels to contain coagula, in inspections made from two hours to five days after death. ("Med. Gaz.," vol. 46, p. 478.) Hence it follows that the blood may be found either coagulated or uncoagulated in those who go into the water living, and die by drowning.

The *lungs* are sometimes congested, and more generally distended than collapsed. Casper and Kanzler, as a rule, found them much increased in volume, and completely filling the cavity of the chest, so that when the chest was opened they protruded out of it; but this did not depend on mere fulness of blood. The most accurate observations show in recent cases of drowning, that the lungs are generally distended and in a flabby condition. Owing to the penetration of their substance by water, they have lost their usual elasticity, so that an impression made upon them by a finger is preserved, as in an oedematous limb. Riedell has pointed out this flabby and dilated condition of the lungs as a special characteristic of drowning; although they floated, he found that they were three or four times as heavy as in their natural state, owing to the water in their substance. ("Med. Gaz.," vol. 46, p. 478.) On making a section of any part of the lungs, a bloody frothy liquid escapes—air and water being mixed together in the air-cells. These appearances are only likely to be observed in a well-marked form, when the body is examined soon after death. The *windpipe*, *bronchi*, and minute *air-tubes* of the lungs, in a recently drowned body, are filled more or less with a *mucous froth* tinged with blood, as a result of the last violent efforts at respiration, when the mouth has sunk below the level of the water. This appearance is not always met with. Thus it has not been found in the bodies of those who have sunk at once below the surface and have not again risen to breathe. But from recent experiments on animals, made by the committee of the Medico-Chirurgical Society, its presence in the air-passages does not depend on the fact of a person rising to the surface—although this may increase the quantity—but rather upon the violent spasmodic efforts made to breathe, under circumstances in which water alone can enter the lungs. These facts show that a mucous froth is produced in the air-passages even in two minutes, when there is entire submersion of the head; and its quantity appears to be in proportion to the length of submersion, and the violence of the efforts made to breathe.

The presence in the air-passages of a mucous froth, frequently tinged with blood, may be regarded as a special character of asphyxia by drowning. When discovered in the lungs, associated with a watery condition of these organs, it furnishes a satisfactory proof of this mode of death. As its presence depends on the retention of air in thin vesicles diffused through the air-tubes, it is obvious that, except in recent inspections, *i. e.*, within a few hours of death, it may have wholly or partly disappeared. Water passing in and out by the windpipe may destroy it—also the exposure of the body to a high temperature. This may account for the fact that it is not always observed in the inspection of the bodies of the drowned, when removed from water. Violent efforts at breathing may, however, produce it—especially if, owing to the loss of power of swallowing, any liquid should find its way into the windpipe. Inde-

pendently of the presence of *water* (sometimes mixed with mud, sand, or weeds) in the larger air-tubes, a portion of this liquid is generally drawn into the lungs by convulsive efforts at respiration. It fills the cells and penetrates the substance of the organs, giving to them the flabby or doughy consistency already described. In some cases the contents of the stomach may be found in the windpipe and lungs; this occurs when the person has been drowned with a full stomach; vomiting takes place, and the vomited matters are drawn into the lungs by the attempt to breathe. According to Tardieu, the state of the lungs is different from that observed in death from suffocation. He found great congestion of the lungs, but no sub-pleural ecchymoses. If these were present it would, in his opinion, indicate that the deceased had been suffocated before being thrown into the water. ("Ann. d'Hyg.," 1855, vol. 2, p. 307; also, Juillet, 1878, p. 174.) According to Bergeron, they are sometimes present in cases of drowning, and the intensity of congestion and the extent of the ecchymoses (not punctiform) are always in proportion to the struggles of the animal.

The state of the *heart* in the drowned has given rise to some discussion. In death from asphyxia the right cavities generally contain blood, while the left cavities are either empty, or they contain much less than the right. Out of fifty-three inspections made by Dr. Ogston, the right cavities were found empty only in two cases, and the left cavities empty in fourteen. ("Med. Gaz.," vol. 48, p. 291.) In a case of drowning which was examined by Mr. Bishop, the right side of the heart contained scarcely any blood; and in another case, communicated to me in December, 1857, the only medical difficulty regarding death by drowning, presented itself in an emptiness or non-distension of the right cavities of this organ. The facts and observations accumulated by my friend, Dr. Norman Chevers, show that a full condition of the heart, although a common, is not an invariable concomitant of asphyxia, either from drowning or any other cause. ("Medical Jurisprudence for India," 1856, p. 441.) It has been elsewhere remarked, that the action of the heart continues after the stoppage of respiration, and that the period at which this organ ceases to contract is variable. Hence, in some cases there may be sufficient power in the right cavities to contract upon their contents, and to expel, more or less completely, the last traces of blood received from the body. Emptiness of the right cavities of the heart must not, therefore, be regarded as inconsistent with death from drowning; at the same time, it cannot be taken as a proof that the person has died from asphyxia. Dr. Riedell states that in half the number of instances which had fallen under his observation, the two sides of the heart contained equal quantities of blood; in the other half, the right side contained the larger proportion. In one case only, the emptiness of the left side contrasted strongly with the fulness of the right.

A greater or less fulness of the vessels of the *brain* is described as one of the appearances met with in drowning; but this, when it exists, is probably a consequence of a congested state of the lungs. Some remarks have been already made on this subject, and from these it is evident that the state of the cerebral vessels can afford no presumption that death has taken place by drowning. In regard to the cases which

that when two or three are drowned by the same accident, they are not unfrequently found clasped within each other's arms,—a fact which at once proves that they must have been living when submerged: so if a dead body is discovered still holding to a rope, cable, or oar, no further evidence is required to show that the deceased must have died from drowning. In 1877, the body of a gentleman was taken out of a pond on his own estate in Cornwall. His eye-glass was open and firmly grasped in his hand. There is reason to believe that he had fallen into the pond while looking at the fish.

The internal appearances upon which medical jurists chiefly rely as proofs of this kind of death are—first, water in the stomach: and secondly, water with the mucous froth in the air-passages and lungs.

1. *Water in the stomach.*—Dr. Riedell found that in the majority of cases of drowning, water passed into the stomach. In animals previously killed, and placed for twenty-four hours in water with the mouth wide open, no fluid penetrated to the stomach. ("Med. Gaz.," vol. 46, p. 478.) Water commonly passes into the stomach of a living animal while drowning by the act of swallowing. It has been observed, that when an animal is stunned prior to submersion, water does not pass into the gullet, and when syncope occurs none will be found. As a proof that its entrance into this organ depends on the act of swallowing, it may be stated that the quantity in the stomach is greater when an animal is allowed to come frequently to the surface and respire, than when it is maintained altogether below the surface. The power of swallowing is immediately suspended on the occurrence of asphyxia, and in this way we may satisfactorily account for the difference observed in the two cases. The water thus found is in variable quantity; and there are some cases of drowning in which water is *not* present in the stomach. It was found by Dr. Ogston, of Dundee, in five cases out of seven. ("Ed. Med. and Surg. Jour.," Jan. 1837.) Water does not readily penetrate into the stomach of a body which has been thrown in after death; the sides of the gullet applying themselves too closely to each other to allow of the passage of fluid. If putrefaction has advanced to a great extent, some water may enter; but a medical man will easily judge, from the general state of the body, how far this process may have been concerned in the admission of fluid into the stomach and intestines. Orfila has suggested that water may be found in the stomach of a person apparently drowned, in consequence of this liquid having been drunk by the deceased, or artificially injected by another into the stomach after death. It is difficult to conceive under what circumstances the latter objection could be made, or what purpose it would answer; but in relying upon the presence of water in the stomach, it may be admitted that the deceased may have drunk water before his body was submerged. The mere discovery of water in the stomach, except under circumstances to be presently mentioned, is not, therefore, a necessary proof that it has been swallowed during the act of drowning.

It is, of course, presumed that the liquid contained within the stomach is of the same nature as that in which the body is immersed: for it is possible that fresh water may be found in the stomach of a person drowned in salt water, and in such a case it would be obviously improper

for a medical witness to affirm, from the mere presence of water, that the person had died where his body was discovered. If the water contain mud, straw, duckweed, moss, or any substance like those existing in the pond or river where the drowning occurred, this is a proof, when the inspection is recent, of its having been swallowed by a living person. The absence of water from the stomach cannot, however, lead to the inference that the person has not died from drowning, because in some instances it is not swallowed, and in others it may drain away and be lost after death before an inspection is made.

2. *Water with mucous froth in the air-passages and lungs.*—If the body is carefully removed from the water, and is examined soon after removal, these appearances, which furnish satisfactory evidence of death from drowning, will be found. Dr. Riedell regards the presence of a mucous froth as a constant sign of this kind of death. In all his experiments and observations he states that he found a frothy fluid in the windpipe, bronchi, and lungs; after death it gradually disappeared from the air-tubes by exosmosis, but not from the lungs. The fluidity of this froth is, he contends, a distinctive character of death from drowning, and is not met with in any other case. ("Med. Gaz.," vol. 46, p. 478.) These observations, made long since by Riedell, have been lately confirmed by others made at the Morgue by MM. Bergeron and Montano. The existence of a mucous froth in the fauces, larynx, and bronchi is, according to them, the only constant sign of death by submersion, whether syncope or asphyxia preceded death. They found it in animals narcotized previously to being thrown into water. The presence of a frothy fluid would undoubtedly show that liquid, from some cause, had penetrated into the air-passages; and when taken in conjunction with the presence of water in the substance of the lungs, it may be considered to furnish conclusive evidence of death from drowning. On the other hand, its absence does not necessarily prove that a person has not died from this cause. There may have been no convulsive efforts at breathing prior to death. A mucous froth may not be found when the body has remained for a long period in the water after death, since by the free passage of this fluid into and out of the air-tubes, the froth, although formed in the first instance, may have disappeared. If, after removal from the water, the body is exposed to the air for several days before it is examined, it is rare that this appearance is seen. The mucous froth may have been formed in the air-passages, but it may have entirely disappeared.

3. *Water and foreign substances in the lungs.*—It has been elsewhere stated that in the act of drowning, water is drawn with considerable force into the lungs, by violent attempts at inspiration. The aspiratory force thus exerted by the lungs is considerable. It has been found that when the heads of animals were plunged below mercury, some of this fluid metal, in spite of its great density, was actually drawn into the lungs, and globules of it have been found in the air-cells. *A fortiori*, this takes place in a greater degree with water, which is forcibly drawn into, and permeates, the spongy texture of the lungs, rendering recovery more difficult and death more rapid than in other forms of asphyxia. This aspiratory force of the lungs has been measured, and is

I have had an opportunity of examining, the quantity of blood contained within the cerebral vessels has rarely been so great as to call for particular notice.

In examining the abdomen, it will commonly be found that the *stomach* contains water, which appears to enter into this organ by the act of swallowing during the struggle for life. This may be salt or fresh, according to the medium in which the drowning has taken place. The quantity is subject to great variation; sometimes it is large, at other times small, and in some instances no water whatever is to be met with. The absence of water may probably indicate a rapid death, as there could have been no power to swallow. Orfila has remarked that the mucous membrane of the stomach and bowels is occasionally much discolored in drowned subjects. He observed also, that when drowning took place while the process of digestion was going on, the mucous membrane of the stomach often had a pinkish-red or violet tint. When the dead body had remained a long time in water, this membrane was observed to acquire a deep violet or brown color. A knowledge of this fact may be of some importance in those cases in which a person is suspected to have been poisoned previously to submersion. It has been said that the diaphragm is generally much raised toward the chest; but this may have depended on gaseous putrefaction, and the increase in the size of the abdomen by the formation of gas in the intestines. The urinary bladder in some cases contains urine—in others, it is perfectly empty. Casper found it empty in one-half of the cases which he examined. It is obvious that the state in which the bladder is found must depend on its condition at the time at which the drowning occurred. (See, in reference to the appearances in the drowned, a paper by Dr. Ogston, "Med. Gaz.," vol. 47, pp. 763, 854, et seq.; also, another by Dr. Riedell, "Med. Gaz.," vol. 46, p. 478; and Casper, "Ger. Leich.-Oeffn.," vol. 1, p. 87; 2, p. 105; "Klinische Novellen," 1863, p. 523.)

MM. Bergeron and Montano conclude from their post-mortem examinations of drowned bodies brought to the Morgue in Paris, that the constant and certain sign of death by drowning is the presence of mucous froth not only in the mouth, but in the larynx and bronchial tubes. There was always some degree of congestion, and occasionally of ecchymosis under the pleura, but this membrane never presented the dotted appearance seen after death from suffocation. The intensity of this congestion in animals drowned for experiment was in proportion to the struggles made by the animal.

Was death caused by drowning?—For a correct solution of this question, it will be necessary to consider the appearances met with in the drowned, and to determine how far they are characteristic of this form of death. Among the *external* signs of drowning, when the body is seen soon after death, are paleness of the surface, a contracted state of the skin (*cutis anserina*), and the presence of a mucous froth about the nostrils and lips. The absence of these appearances, however, would not prove that the person had not been drowned; for if the body had remained some time in water, or if it had been long exposed to air before it was seen by a medical man, the skin would undergo various changes

in its condition and color, and mucous froth would no longer be found adhering to the lips and nostrils.

State of the skin.—The goose-skin, or cutis anserina, which is frequently observed in the drowned, indicates that the skin possessed the living power of contractility at the time of immersion. Wagner suggests that the appearance might be produced in a dead body if thrown into cold water immediately after death, *i. e.*, while the skin is warm. As none but assassins would be likely to resort to this proceeding, the objection would, if admitted, merely leave the fact of drowning still to be made out by an internal inspection. This contracted state of the skin could hardly be mistaken for a natural rough or horny skin, as suggested by Casper. ("Ger. Leich.-Oeffn.," vol. 1, p. 89.) As this condition of the skin is invariably present, even in the recently drowned, and as it is observed chiefly in drowning during cold weather, its absence must not be taken to negative the hypothesis of drowning.

A case may present itself in which an observation of this kind may furnish important information. Thus in the case of *Reg. v. Makins*, the prisoner was charged with the murder of her child. There was evidence that she had given an opiate to the child, and that while its body was still warm she had immersed it in ice-cold water, as it was suggested in defence with the intention of rousing it. This point could not be settled, as the medical man did not notice the state of the skin. The prisoner was acquitted.

Substances grasped in the hands.—Foreign substances, such as gravel, dirt, grass, or weeds, are sometimes found locked within the hands or lodged under the nails of the drowned subjects. This fact may occasionally afford strong circumstantial evidence of the manner in which a person has died. If the materials are found grasped within the hands of the deceased which have evidently been torn from the banks of a canal or river, or from the bottom of the water in which the body is found, we have strong presumptive evidence that the person died within the water. For although it is possible to imagine that the deceased may have struggled on the bank, and had been killed prior to submersion, yet in the value attached to this sign we are assuming that there are no marks of violence on the person, nor any other appearances about the body sufficiently striking to lead the examiner to suspect that death had occurred in any other way than by drowning. If the substance locked within the fingers or finger-nails is sand of the same character as that existing at the bottom of the river or pond, it is difficult to conceive any stronger fact to establish death from submersion. The abrasion of the fingers is a circumstance of minor importance: no value could be attached to this state of the fingers as an indication of a person having perished by drowning, unless it were in conjunction with the appearances above described. A witness would be constrained to admit, in many cases, that the fingers might become abraded or excoriated after death, or even before submersion; while in no case could he be called upon to make, in regard to substances found grasped within the hands, an admission which would invalidate the evidence deducible from this condition. This must then be regarded as a satisfactory proof of a person having been alive after his body was in the water. It is well known

that when two or three are drowned by the same accident, they are not unfrequently found clasped within each other's arms,—a fact which at once proves that they must have been living when submerged: so if a dead body is discovered still holding to a rope, cable, or oar, no further evidence is required to show that the deceased must have died from drowning. In 1877, the body of a gentleman was taken out of a pond on his own estate in Cornwall. His eye-glass was open and firmly grasped in his hand. There is reason to believe that he had fallen into the pond while looking at the fish.

The internal appearances upon which medical jurists chiefly rely as proofs of this kind of death are—first, water in the stomach; and secondly, water with the mucous froth in the air-passages and lungs.

1. *Water in the stomach.*—Dr. Riedell found that in the majority of cases of drowning, water passed into the stomach. In animals previously killed, and placed for twenty-four hours in water with the mouth wide open, no fluid penetrated to the stomach. ("Med. Gaz.," vol. 46, p. 478.) Water commonly passes into the stomach of a living animal while drowning by the act of swallowing. It has been observed, that when an animal is stunned prior to submersion, water does not pass into the gullet, and when syncope occurs none will be found. As a proof that its entrance into this organ depends on the act of swallowing, it may be stated that the quantity in the stomach is greater when an animal is allowed to come frequently to the surface and respire, than when it is maintained altogether below the surface. The power of swallowing is immediately suspended on the occurrence of asphyxia, and in this way we may satisfactorily account for the difference observed in the two cases. The water thus found is in variable quantity; and there are some cases of drowning in which water is *not* present in the stomach. It was found by Dr. Ogston, of Dundee, in five cases out of seven. ("Ed. Med. and Surg. Jour.," Jan. 1837.) Water does not readily penetrate into the stomach of a body which has been thrown in after death; the sides of the gullet applying themselves too closely to each other to allow of the passage of fluid. If putrefaction has advanced to a great extent, some water may enter; but a medical man will easily judge, from the general state of the body, how far this process may have been concerned in the admission of fluid into the stomach and intestines. Orfila has suggested that water may be found in the stomach of a person apparently drowned, in consequence of this liquid having been drunk by the deceased, or artificially injected by another into the stomach after death. It is difficult to conceive under what circumstances the latter objection could be made, or what purpose it would answer; but in relying upon the presence of water in the stomach, it may be admitted that the deceased may have drunk water before his body was submerged. The mere discovery of water in the stomach, except under circumstances to be presently mentioned, is not, therefore, a necessary proof that it has been swallowed during the act of drowning.

It is, of course, presumed that the liquid contained within the stomach is of the same nature as that in which the body is immersed; for it is possible that fresh water may be found in the stomach of a person drowned in salt water, and in such a case it would be obviously improper

for a medical witness to affirm, from the mere presence of water, that the person had died where his body was discovered. If the water contain mud, straw, duckweed, moss, or any substance like those existing in the pond or river where the drowning occurred, this is a proof, when the inspection is recent, of its having been swallowed by a living person. The absence of water from the stomach cannot, however, lead to the inference that the person has not died from drowning, because in some instances it is not swallowed, and in others it may drain away and be lost after death before an inspection is made.

2. *Water with mucous froth in the air-passages and lungs.*—If the body is carefully removed from the water, and is examined soon after removal, these appearances, which furnish satisfactory evidence of death from drowning, will be found. Dr. Riedell regards the presence of a mucous froth as a constant sign of this kind of death. In all his experiments and observations he states that he found a frothy fluid in the windpipe, bronchi, and lungs; after death it gradually disappeared from the air-tubes by exosmosis, but not from the lungs. The fluidity of this froth is, he contends, a distinctive character of death from drowning, and is not met with in any other case. ("Med. Gaz.," vol. 46, p. 478.) These observations, made long since by Riedell, have been lately confirmed by others made at the Morgue by MM. Bergeron and Montano. The existence of a mucous froth in the fauces, larynx, and bronchi is, according to them, the only constant sign of death by submersion, whether syncope or asphyxia preceded death. They found it in animals narcotized previously to being thrown into water. The presence of a frothy fluid would undoubtedly show that liquid, from some cause, had penetrated into the air-passages; and when taken in conjunction with the presence of water in the substance of the lungs, it may be considered to furnish conclusive evidence of death from drowning. On the other hand, its absence does not necessarily prove that a person has not died from this cause. There may have been no convulsive efforts at breathing prior to death. A mucous froth may not be found when the body has remained for a long period in the water after death, since by the free passage of this fluid into and out of the air-tubes, the froth, although formed in the first instance, may have disappeared. If, after removal from the water, the body is exposed to the air for several days before it is examined, it is rare that this appearance is seen. The mucous froth may have been formed in the air-passages, but it may have entirely disappeared.

3. *Water and foreign substances in the lungs.*—It has been elsewhere stated that in the act of drowning, water is drawn with considerable force into the lungs, by violent attempts at inspiration. The aspiratory force thus exerted by the lungs is considerable. It has been found that when the heads of animals were plunged below mercury, some of this fluid metal, in spite of its great density, was actually drawn into the lungs, and globules of it have been found in the air-cells. *A fortiori*, this takes place in a greater degree with water, which is forcibly drawn into, and permeates, the spongy texture of the lungs, rendering recovery more difficult and death more rapid than in other forms of asphyxia. This aspiratory force of the lungs has been measured, and is

and hence that the deceased has been drowned. An examination of the condition of the stomach and lungs together, will therefore be of importance in cases of alleged child-murder by drowning, since it may be proving or disproving the charge.

When a dead body is thrown into water, and has remained there some time, water with fine particles of sand, mud, or weeds, may pass through the windpipe into the lungs, and be there deposited. Water under such circumstances, however, does not penetrate into the substance of the lungs as by aspiration during life, and the amount which passes through the chink of the glottis is small. If simply an after-death effect, water is found in the larger air-tubes unaccompanied by mucous froth. In most cases, however, the effect of aspiration as a result of living drowning is so manifest, that the examiner can have no difficulty in forming an opinion.

A medical man may be occasionally required to express an opinion as to the length of time that may have elapsed since the act of drowning, when the dead body of a person has been discovered in water. The observations which have been suggested for the guidance of a medical witness on these occasions are open to so many exceptions, owing to the different degrees in which putrefaction takes place in bodies exposed under such circumstances, that they are of but little service as a basis for medical evidence. From these observations it will be perceived that the characters on which reliance can be placed, as medical proofs of drowning, are—first, the presence of a mucous froth in the windpipe and air-tubes; secondly, of water in the air-tubes and air-cells of the lungs; and thirdly, of water in the stomach. An early inspection of the body may thus enable a medical man to come to a satisfactory conclusion that death was or was not caused by drowning. The longer this inspection is delayed, the more ambiguous the evidence becomes, since the froth slowly disappears from the air-tubes, while water slowly penetrates into the lungs and stomach. The great cause of failure in obtaining medical proofs of drowning, is generally the unavoidable delay before an inspection is made.

If, in examining a body taken from the water, we find upon it no signs of violence, or of any internal injuries sufficient to destroy life, the

In consequence of the uncertainty attendant on the appearances of drowning, barristers have considerable advantage in cross-examining those medical witnesses who appear to support the theory of the prosecution that death took place from this cause. Legal ingenuity is here often strained to the utmost, to show that there is no certain *sign* of drowning, and therefore that the deceased must have died from some other cause. The general impression among non-medical persons appears to be that, whether in drowning or suffocation, there ought to be some particular *visible change* in some part of the body to indicate at once the kind of death; but it need hardly be said that this notion is founded on false views, and if the reception of medical evidence on the cause of death be made to depend on the production of some such positive and visible change of structure, then it would be better at once not to place the parties charged with the crime upon their trial, because it could never be proved against them. A medical inference of drowning is founded upon a certain series of facts, to each of which, individually, it may be easy to oppose plausible objections; but taken together they furnish cumulative evidence as strong as is commonly required for proof of any kind of death.

In death from drowning a question respecting the *specific gravity* of the human body may incidentally arise. In the healthy living body this is made up of the combined specific gravities of its different parts; so that, as in all heterogeneous solids, it is a complex quantity. In the first place, about 72 per cent. of the weight of the body consists of water—hence the question of specific gravity can refer only to the remaining 28 per cent. of dry solids. The only part of the body which is lighter than water is fat. The specific gravity of this is 0.92, and it is calculated that the proportion of fat in an adult is about five per cent. of the weight of the body, or one-twentieth part. The specific gravity of muscle is 1.085, of brain 1.04, of the soft organs generally 1.05, of the lungs containing air 0.94, and of bone, the heaviest part of the body, 2.01. The lightness of the fatty portions is more than counterbalanced by the weight of the skeleton (about ten and a half pounds in the male, and nine pounds in the female), so that the naked human body, placed on water, has a slight tendency to sink. This tendency diminishes just in proportion to the quantity of the body immersed; because all those parts which are out of water, not being supported by water, become so much additional absolute weight to the portion immersed. Hence the frequent cause of death by drowning. An inexperienced person exhausts himself by exertion, raises his arms continually out of the water, and as often sinks, owing to their weight having just so much effect on his body as if a leaden weight had been suddenly applied to his feet to sink him. When the *whole* of the living body is immersed, the specific gravity, owing to the expansion of the chest, differs so little from that of water that a very slight motion of the hands or feet will suffice to keep a person on the surface. The head, owing to the weight of the bones of the skull, has always a tendency to sink below the level of water, and muscular force is required to keep it above the surface. Dr. Neil Arnott has calculated from the weight of water displaced, that the bulk of the adult body is equal to two and a half cubic feet. This is the quantity displaced by

total immersion, and its weight is about 156 pounds. There are two circumstances which cause the specific gravity of the body to vary. The quantity of *fat* is proportionably large, it will be diminished; and a person will float more readily than another in an opposite condition. On the other hand, a large proportion of *bone* renders a person heavier than his bulk of water; and his body will sink more rapidly than that of another. These two modifying causes of buoyancy are liable to constant variation; hence the different accounts given by experimenters relative to the specific gravity of the human body. The bodies of women are, *cæteris paribus*, of less specific gravity than those of men; the skeleton is smaller, and there is a greater proportion of fat—hence women float more readily. The bodies of infants and young children float with the greatest ease; the quantity of fat is usually in large proportion to the bones are light—the earthy matter being not yet fully deposited. Thus, in infanticide by drowning, the body of the child rises very speedily to the surface,—if, indeed, it does not remain altogether upon it.

There are some other points to be considered in relation to the buoyancy of the living human body. 1. *Respiration*.—It is the fact of the lungs being filled with air that gives the general lightness to it. If the respiratory organs are emptied while the face is under water and the person cannot inhale again, the body remains specifically heavier than water and sinks. Hence it follows that, *cæteris paribus*, a person with a large capacious chest, floats more easily than one whose chest is small and contracted. Hence, also, in a living person the body has a tendency to rise out of water during inspiration, and to sink during expiration. The quantity of water displaced under these two opposite conditions of the respiratory organs being very different. The entrance into water with the chest nearly emptied as the result of a loud scream or shriek is unfavorable to the buoyancy of the body. The fact of *clothes* being on the person may also make a difference—either, from their nature serving to buoy up the body, or from their weight to sink it more deeply. Women are sometimes saved from drowning by reason of their chest floating, and thus presenting a large surface to the water; it is owing to this circumstance that the bodies of drowned women remain floating on the water immediately after death.

It may be laid down as a general rule, that the recently *dead* and unclothed is, when left to itself, *heavier* than water, and sinks when immersed. The expulsion of air from the lungs and their penetration by water, combined with the fact that the bones and all the soft parts, excepting the fat, are of greater specific gravity than water, afford a suffi-

require but little air to keep it at or near the surface of the water. But a dead body, whether death has been caused by drowning or not, may not sink at all, owing to some one of the counteracting causes above mentioned. Several cases are reported in which the bodies of persons recently drowned have floated.

Marks of violence on the drowned.—The chief inquiry with regard to marks of violence on the bodies of the drowned is whether they have resulted from accident or design. In forming an opinion, a witness must give due value to the accidents to which a body floating loosely in water may be exposed. Bruises or ecchymoses of considerable extent are sometimes seen on the drowned, when the bodies have been carried by a current against mechanical obstacles in a navigable river or canal. If the deceased fell from a considerable height into water, his body in falling may have struck against a rock or projection, which may have produced extensive marks of violence. Dead bodies taken out of wells often present considerable marks of violence of a vital character when the deceased persons have fallen in accidentally, or have thrown themselves in intentionally. The presence of these marks must not create a hasty suspicion of murder. It is manifestly impossible to lay down any specific rules for forming a decision in cases of this kind, since, probably, no two instances will be met with which will be perfectly similar in the details. In clearing up these doubtful points, everything must depend on the tact and experience of the practitioner who is called upon to conduct an investigation. There may be a severe cut in the throat arising from a previous attempt at suicide, as in the case of *Sands* (July, 1878), who destroyed his three children by cutting their throats, and then cut his own throat; but as the wound involved only the branches of the external carotid artery, he was able to walk to a pond about thirty yards away, in which his dead body was subsequently found. The first question which a medical jurist has to determine is, whether the wounds or injuries on the body were produced before or after death. (See WOUNDS, *ante*, p. 260.) If after death, then they ought to be obviously of accidental origin. If the injuries show intentional violence, it will be proper to consider whether they are such as to be consistent with a suicidal attempt, or whether they indicate homicide. (See WOUNDS, p. 276.) Men have been known to produce very severe wounds on the throat resembling homicidal wounds, and still to have retained the power of throwing themselves into a pond or canal. A case of this kind was the subject of an inquest in this district in 1877. In August, 1878, the dead body of a man was found in the Serpentine with a bullet wound traversing the chest in the region of the heart, likely to have caused immediate death. It was proved that deceased had been seen on the parapet of the bridge with a revolver, and that immediately after the report of a pistol, his body had been seen to fall over into the river. Thus were the facts readily explained.

Accidental violence may sometimes be of a serious nature, so serious that a practitioner might well doubt whether it did not indicate that the deceased had been violently treated prior to submersion. If a dead body were taken out of water, with one or both limbs dislocated, or the vertebræ of the neck fractured, and a surgeon was asked whether such injuries could be accidental and coincident with or consequent on drown-

ing, the answer would probably be in the negative. But an instance has occurred in which both arms of a man were accidentally dislocated at the shoulders in the act of drowning, as a result of a fall into the water from a great height.

The great point with regard to all marks of violence on the drowned, is to throw light upon the questions—1st, whether drowning was really the cause of death; and 2dly, whether, if so, the act was the result of accident, suicide, or homicide. This last question does not concern a medical witness so much as a jury, who will determine it from the facts, medical and general, proved before them.

There is one case, of rare occurrence, in which a practitioner would be apt to be misled by trusting to appearances found on the drowned. If a dead body were removed from water with a deep ecchymosed circle round the neck, evidently produced by a cord or ligature, but no traces of which could be found, it is not improbable that a strong suspicion would be at once raised that deceased had been murdered by strangulation, and the body afterwards thrown into water. A case occurred some years since, in which a mark was produced on the neck of a woman who was accidentally drowned, as a result of the compression produced by the string of her cloak. Marks resembling those of strangulation, have been produced on the necks of bodies floating in water, when soon after death they have been driven by a strong current against the stumps of trees or other obstacles in the stream. It might be said, that in cases of this description, circumstantial evidence would commonly show how the mark had originated. In admitting the truth of this observation, we must remember that circumstances, as matters of proof, do not always present themselves to our notice, or occur to our judgment, at the precise time that the law stands most in need of them. While, then, we use great caution in drawing an inference when there are such strong grounds for suspicion, we should not neglect to examine carefully the slightest appearances of violence on a body.

Fractures are not often met with in the drowned as the result of accident. Certain fractures likely to be followed by immediate death may forbid the supposition of their having occurred after drowning, and a careful examination of the body may show that they were not likely to have arisen from accident at or about the time of submersion. The medico-legal question has arisen whether fractures of the *vertebræ of the neck* can occur from accident alone, at or about the time of drowning. In August, 1858, a gentleman, in jumping from a bathing-machine head-foremost into water more shallow than he had expected, caused a fracture and displacement of the cervical *vertebræ*, which led to death. A similar accident occurred at the Albany Baths in 1877. The deceased in this case dived—rose to the surface foaming at the mouth, and immediately sank. He was removed from the water and taken to St. Thomas's Hospital. He recovered consciousness, but lost all power in his limbs from his arms downwards. He soon died, and it was found that there was fracture and displacement of the *vertebræ of the neck*. The accident was caused by deceased's head coming in contact with the brick bottom of the bath. Mr. South quotes the case of a man who threw himself into a river to bathe from a height of seven or eight feet, the

water being only three feet deep. He rose to the surface, but fell back senseless. When he recovered his consciousness, the account he gave of the accident was, that he felt his hands touch the bottom of the river, but to save his head drew it violently back, upon which he lost all consciousness. He died in about ten hours, and on examination the skin of the back of the neck was much ecchymosed, the interspaces of the muscles were gorged, and the spinal canal was filled with blood. The body of the fifth vertebra of the neck was broken across about the middle of its depth, and the two pieces were completely separated from the lateral parts. As there was no mark of contusion or dirt on the head, Reveillon, who reports the case, believes that the fracture arose from muscular action, and not from a blow received by striking the bottom: but this is doubtful. In another instance related by Mr. South, a sailor jumped headlong into the sea to bathe, a sail being spread three feet below the surface. He immediately became motionless, and died in forty-eight hours. The fourth and fifth vertebræ of the neck were found exclusively fractured, and the spinal marrow was crushed and lacerated. ("Chelius's Surgery," Part 6, Fractures.) In this case the fracture must have resulted from contact with the water or the sail; but as the latter was freely floating, this would be a yielding medium: hence this serious injury may occur accidentally in cases in which we might not be prepared to look for it. Dr. Delens has recently directed attention to fractures and other injuries found on the drowned bodies recovered from the Seine, in Paris. Some of these have been wrongly referred to acts of murderous violence. ("Ann. d'Hyg.," Nov. 1878, p. 453.)

There is some reason to believe that cases of homicidal violence are frequently overlooked in the inspection of bodies found in water. (See "Brit. Med. Jour.," Jan. 19, 1878.) There is usually no post-mortem examination made for a coroner's inquest, the external inspection is hastily conducted, and the common verdict of "found drowned" means simply found in the water!

Was drowning the result of homicide, suicide, or accident?—Drowning is a frequent cause of death. From a return made to the House of Commons in 1878, it appears that the total deaths by drowning in the inland waters of England and Wales during the year 1877 were 2662,—namely, 2140 males and 522 females. Of the 2662, 1423 perished in rivers or running waters, 637 in canals, and 602 in lakes or ponds. Although the question whether the act of drowning was the result of suicide or murder properly falls within the province of a jury, there are certain points in relation to it, which require to be noticed by a medical witness. In the first place, it is not to be imagined that an examination of the body, will show any differences in either of the three supposed kinds of death. So far as the phenomena of drowning are concerned they are the same, and they are accompanied by the same appearances after death in each case. In drowning which is accidental or suicidal it is not usual, as it has already been observed, to meet with marks of violence on the person, except such as are purely of *accidental* origin, and have commonly been produced *after death*. In accidental drowning this is almost a constant rule: but if the person has fallen from any height, his body may be injured by the fall, either by projections on the banks

of a river or canal, or by mere concussion on the water—allowance for either of which we must be prepared to make, according to the situation of the spot from which the person is supposed to have fallen.

It is calculated that in England drowning is the cause of death in nearly one half of all suicides; but this of course will vary according to localities. In *suicidal* drowning we have a difficulty to encounter which we do not meet with in that which is *accidental*. A man may have attempted suicide by some other means previously to throwing himself into the water: thus then, besides the accidental violence of accidental drowning, we may meet with violence on the person, evidently indicating wilful perpetration. What is the nature of this violence?—Is it to be defined? Can it always be distinguished from that which is positively *homicidal*? The answers to these questions must depend on the circumstances proved in each case.

Drowning in shallow water.—Homicide has been sometimes presumed from the peculiar circumstances under which a body has been discovered. Thus, for instance, it has been a debated question whether a person intent on suicide can voluntarily drown himself in *shallow* water, as in a bath, by turning upon his face and retaining this position with his mouth below the level of the water. This question has been long since settled in the affirmative by the occurrence of well-authenticated cases. It appears to have been raised originally on the theoretical view that the resolution of a suicide would fail him in such a situation, and that, having the means of escape, he would lose no time in extricating himself. It need hardly be stated that the mere immersion of the mouth in water not more than a few inches deep will produce all the phenomena of death by drowning; with the exception that little or no water would probably be found in the stomach. A man may thus die in two or three minutes. Devergie mentions an instance which occurred in May, 1833, where a man was found drowned in a small stream, his face towards the ground, and his head just covered by the water, which was not more than a foot in depth. On dissection there were all the appearances of drowning present, and a large quantity of sand and gravel was found occupying the windpipe and smaller air-tubes. (Op. cit., vol. 2, p. 332.) In Nov. 1874, a drunken man fell with his head across a shallow ditch. He was found dead, and it was obvious that his body had so dammed up the water that it had flowed over his face and thus caused his death by drowning. He was powerless to save himself. A case is mentioned by Dr. Smith, in which a woman committed suicide by breaking a hole in the ice of a pond during the winter, and thrusting her head into the water, the rest of her body being out. A man was found dead with his face downwards in a small stream of water only six inches deep. The water was so shallow that it did not cover the deceased's body or his head. There was clear evidence that this was a case of suicidal drowning.

Although a person has for a short time the power of removing from a position in which he must speedily die, that power is soon lost. If the mouth is kept below water by a strong voluntary effort for half a minute or longer, the unsaturated blood is circulated through the brain, and the person becomes powerless, so that his fate is not now in his own hands. Lunatics and other persons have thus destroyed themselves in shallow baths, although left unwatched by the attendant for only four or five

minutes. The discovery of dead bodies under these circumstances is, therefore, quite consistent with suicide, but it does not necessarily prove that the act was suicidal. It cannot be denied that a person if young or enfeebled by disease or age, may be held by others in such a position sufficiently long to produce death from drowning, but if he is capable of making resistance, we ought to find some marks of violence on the limbs or body. So, again, such a position is by no means incompatible with accidental drowning; and on this it may happen that a medical practitioner will be called to express an opinion. A man in a state of deep intoxication, or when suddenly attacked by syncope, epilepsy, or apoplexy, may fall with his face in a gutter, ditch, or small pool of water; he may die in this position, not having the power to extricate himself. Even marks of violence on the body must not be too hastily construed into proofs of murder. Not long since a case of this description gave rise to a trial for murder in one of our midland counties. A man was found dead with his face in some melted snow, and there were several severe contusions on his body. The evidence showed that, after a quarrel, he had left a neighboring inn much intoxicated; and it was rendered extremely probable that he had perished accidentally on his way home. There was no reason to suppose that he had been murdered. Infants, from mere helplessness, may be drowned under similar circumstances; but at the same time an assassin may select this mode of destroying life in order to give the appearance of accident.

Drowning from partial immersion.—There is no doubt that murder by drowning may be perpetrated without the *whole of the body* being immersed in water. A case of this kind, which was the subject of a criminal trial, was referred to me by Mr. Aldred, of Norwich, in March, 1841. The case was tried at the Norwich Lent Assizes of that year (*The Queen v. Yaxley*), and the prisoner was convicted. It appears that the mode in which the prisoner destroyed her infant child was by immersing its head for a few minutes in a pail of water. She removed it before it was quite dead; but it soon died, with slight convulsive movements of the limbs. The case was rendered obscure by the fact that the whole of the body had evidently not been immersed; and the only conceivable means of drowning were in a small duck-pond adjoining the house, which was covered with weeds; but no weeds was found in the stomach of the child, although a quantity of water was there present.

Suicide by drowning may take place as the result of partial immersion—the immersion of the head. Several cases of this kind have been lately brought out by coroners' inquests. In Feb. 1877, a Mr. Stagg, of Birmingham, was found dead with his head downwards in a water-butt, and his legs protruding over the top. In May, 1877, a woman was found dead in London. She was in a stooping position on the floor, and her face downward in a pail of water. In April, 1878, a woman was found dead with her head immersed in a water-tank only a foot wide. She had so placed her head that it was under the bar of the ball tap. Again, in March, 1880, a man, æt. 58, was found dead on his knees with his head and shoulders immersed in a tub of water, in which he had been washing some oysters. A medical opinion was given at the inquest that

the man had died from apoplexy, and the jury returned a verdict of death from natural causes. These cases show determined acts of suicide.

Ligatures on the hands and feet.—When a drowned body is removed from water with the hands or the hands and feet bound with cords, it is usually considered that we have therein presumptive evidence of homicide; but numerous cases are recorded in which suicides have actually bound themselves in this manner, or have attached heavy weights to their bodies, before throwing themselves into water, for the express purpose of preventing any chance of their escaping death.

HANGING.

CHAPTER XXXIX.

CAUSE OF DEATH.—DEATH FROM THE SECONDARY EFFECTS.—POST-MORTEM APPEARANCES.—MARK OF THE CORD OR LIGATURE.—WAS DEATH CAUSED BY HANGING?—HANGING AFTER DEATH.—SUMMARY OF MEDICAL EVIDENCE.—MARKS OF VIOLENCE ON THE HANGED.—WAS THE HANGING THE RESULT OF ACCIDENT, SUICIDE, OR HOMICIDE?—THE POSITION OF THE BODY.

Cause of death.—By hanging we are to understand that kind of death in which the body is wholly or partially suspended by the neck, and the constricting force is the weight of the body itself, while in strangulation the constricting force is due to some other cause. In both cases death commonly results from *asphyxia* (p. 59), although this must depend in a great measure upon the position of the ligature on the neck, as well as on the degree of pressure produced. If the cord is loose, or applied to the upper part of the neck, a small quantity of air may still reach the lungs, and then the cerebral circulation may become interrupted by the compression of the great vessels of the neck. In this case apoplexy of the congestive kind is induced, and operates as the immediate cause of death. It is easy to conceive that there may be a mixed condition of asphyxia and apoplexy, and according to the observations of Professors Casper and Remer this is actually met with in a great number of cases of death from hanging. Dr. Holland relates the following case: A man, æt. 57, committed suicide by hanging. After being suspended for an hour, he was cut down by Dr. Holland and two others. As the doubled rope was slackened from the neck, air escaped through the larynx, and a prolonged, rather loud groan was heard. As an explanation, he suggests that the suicide, in hanging himself, drew in a deep breath, and the sudden and violent constriction of the neck retained the air in the chest

until the ligature was removed. ("Brit. Med. Journ.," May, 1875, p. 575.)

It has been observed in the execution of criminals that death takes place at different intervals of time after suspension. This difference is probably dependent on the greater or less degree of constriction produced by the ligature. If the rope should press upon the larynx or above this organ, the closure of the air-passages will not be so complete as if pressed upon the windpipe immediately below the cricoid cartilage. A slight degree of respiration might in the former case continue for a short interval, by which the life of a person would be prolonged, while in the latter, death would be immediate. If the windpipe is in part ossified, the pressure of the ligature is less perfect, and death will then take place more slowly. Louis found that an occasional cause of death in hanging was a displacement of the second vertebra of the neck whereby the spinal marrow was suddenly compressed. As a general rule this cause of death is only likely to be observed in corpulent or heavy bodies, when a long fall is given to the cord, and when much violence has been at the same time employed by the executioner. Fractures of the vertebræ may occur and prove fatal by compressing the spinal marrow. Death may also be caused suddenly, by cerebral congestion from pressure on the bloodvessels, or by the effusion of blood on the spinal membranes. This is likely to happen when the head falls, or is bent suddenly backwards, so that the weight of the body is supported on the back of the neck.

Death from hanging appears to take place very rapidly, and without causing any suffering to the person. It is observed that in those who are criminally executed, there are often violent convulsions of the limbs and trunk. There is no reason, however, to believe that the individual suffers pain, any more than in the convulsions of an epileptic fit. On recovery there is an entire loss of consciousness of pain in both cases. The circulation of dark-colored blood through the brain and spinal cord may account for these effects. Efforts to inspire are made for one or two minutes after the closure or compression of the windpipe. The diaphragm and intercostal muscles act spasmodically, but no air enters the lungs; and it is probable that in the act of hanging, part of the air contained in the organs is convulsively expelled. When the suspension of the body has only continued a few minutes, it has often been found impossible to restore life; and, indeed, the period at which resuscitation may take place varies according to circumstances. Supposing the hanging to be unattended with violence to parts about the neck, some persons might be resuscitated after five minutes' suspension or longer, but then it has been observed that they have subsequently died from secondary causes affecting the brain and nervous system. Others, again, may not be recovered when they are cut down immediately after suspension—a fact which depends probably on the different degrees to which asphyxia or apoplexy has extended. When the ligature is so placed as to press on the windpipe below the larynx, insensibility and death are almost instantaneous.

Death from the secondary effects.—It by no means follows that because we have succeeded in restoring the respiratory process, a person is

safe. Death often takes place by a fatal relapse at various periods after the accident. A case of this description has been published by Sir B. Brodie. A boy, æt. 17, was found hanging. When cut down he was insensible, his face livid; his lips were of a dark purple color, pulse not perceptible, pupils dilated and motionless. Artificial respiration was used, and in a quarter of an hour the diaphragm began to act. He breathed at irregular intervals with stertor, and with a rattling noise in the throat. The pulse became perceptible, but often flagging, and the surface of the body was cold. The countenance was still livid, but the pulse and breathing had improved. At the end of another hour an attempt was unsuccessfully made to take some blood from the arm, and the patient was placed in a warm bath. The breathing was stertorous through the night, and in the morning twelve ounces of blood were taken from the arm; but there was no relief. He continued insensible, and cold on the surface: there was frothing at the mouth, and he died twenty-four hours after he was cut down. The body was carefully examined. The vessels of the brain were very full of blood: this was the only morbid appearance.

We learn from those who have been resuscitated, as well as from experiments performed by persons upon themselves, that the insensibility of asphyxia comes on in the most insidious manner in death from hanging, and that a slight constriction of the windpipe will speedily produce loss of consciousness and muscular power. ("Devergie," 2, 370.) The only symptoms of which the hanged persons have been conscious were a hissing in the ears, a flash of light before the eyes, then darkness and oblivion. The only profitable inference, in a medico-legal view, which can be drawn from observations of this kind is that asphyxia is not only rapidly induced, but that it supervenes under circumstances where it would not be generally expected to occur—*i. e.*, when the weight of the body is in great part supported. M. Fleischmann found that a cord might be placed round his neck between the chin and os hyoides, and tightened either laterally or posteriorly without perceptibly interrupting respiration; but while the respiratory process was thus carried on, his face became red, his eyes prominent, and his head felt hot. These symptoms were followed by a sense of weight, a feeling of incipient stupefaction, and a hissing noise in the ears. On the occurrence of this last symptom, the experiment, he says, should be discontinued, or the consequences may be serious! His first experiment on himself lasted two minutes; but in the second, owing to the cord by its pressure more completely interrupting respiration, the noise in the ears appeared in *half a minute*. When the pressure was applied on the windpipe the effect was *instantaneous*, but when on the cricoid cartilage, it was not immediate. If it was applied between the os hyoides and the thyroid cartilage, or on the os hyoides itself, the period during which a person could breathe was extremely short; and this result was more striking when the act of expiration was performed at the moment of applying the pressure.

The death of *Scott*, the American diver, in January, 1840, shows how readily asphyxia may be induced by a slight compression of the throat, even when a person might be supposed to have both the knowledge and the power to save himself. This man was in the habit of making public

experiments on hanging, and had frequently before gone through them without danger; but on the last occasion, it is probable that a slight shifting of the ligature from under the jawbone caused so much compression on the throat between the chin and larynx, as speedily to produce asphyxia. No attempt was made to save him until it was too late, and he was not brought to a hospital until thirty-three minutes had elapsed. He was allowed to hang *thirteen minutes*,—the spectators thinking that the deceased was only prolonging the experiment for their gratification! The very insidious and painless manner in which a person who is suspended passes from life into death, is also well illustrated in the report of the case of *Hornshaw*, published by Dr. Chowne. ("Lancet," April 17, 1847, p. 404.) This man was on three occasions resuscitated from hanging,—a feat which, like Scott, he had performed in London for public gratification. He stated that on the last occasion he lost his senses almost at once; it seemed as if he could not get his breath, and that some great weight was attached to his feet; he felt that he could not move his hands or legs to save himself, and that the power of thinking was gone. It is not improbable that many persons have thus lost their lives by privately attempting these experiments, and their cases have been wrongly set down to acts of suicide. There is reason to believe that boys have thus frequently but unintentionally destroyed themselves, from a strange principle of imitation or curiosity. Dr. Elliott, of Carlisle, communicated to me the following case, which came before him as coroner in April, 1874. A boy, æt. 11, in order to frighten his parents, tied a knot in his handkerchief, and put one part of it over the knob of the upright at the foot of the staircase, and the other underneath his chin, so that it did not go round his neck. His dead body was found suspended in the loop, which had pressed against the windpipe and produced speedy unconsciousness. He died quietly, without struggling.

Post-mortem appearances.—The *external* appearances met with in the hanged, have been generally taken by medico-legal writers from those seen in the bodies of persons who have been criminally executed, or who have been violently hanged. Thus among them are the following: Lividity and swelling of the face, especially of the lips, which appear distorted: the eyelids are swollen, and of a bluish color; the eyes red, projecting forwards, and sometimes partially forced out of their cavities; the tongue enlarged, livid, and either compressed between the teeth or sometimes protruded; the lower jaw is retracted, and a bloody froth sometimes exists about the lips and nostrils. There is a deep and ecchymosed impression around the neck, indicating the course of the cord, the skin being occasionally excoriated; laceration of the muscles and ligaments in the hyoideal region; laceration or contusion of the larynx, or of the upper part of the windpipe. There are also, commonly, circumscribed patches of ecchymosis varying in extent, about the upper part of the body and the upper and lower limbs, with a deep livid discoloration of the hands; the fingers are generally much contracted or firmly clenched, and the hands and nails, as well as the ears, are livid; the urine, feces, and spermatic fluid are sometimes involuntarily expelled at the moment of death. Such appearances will rarely be found in those cases of suicidal hanging which are likely to come before a medical prac-

The tongue is not always protruded. Devergie found that there was protrusion of this organ in eleven cases out of twenty-seven. This protrusion was formerly supposed to depend upon the position of the larynx: thus it was said, when this was below the cricoid cartilage, the whole of the larynx was drawn upwards, and the tongue carried forward with it, while, when above the os hyoides, the tongue was drawn backwards. The protrusion or non-protrusion of the tongue does not depend upon any mechanical effect of this kind, but simply upon congestion of the tongue, which is occasionally met with thus protruding in cases of drowning and strangulation. Besides, the protrusion has not been found to have any relation to the position of the ligature.

There is another appearance on which a remark may be made—the state of the hands. As a general rule, in violent hanging or strangulation, the hands are clenched. This appearance may not always be found, as it may exist and be destroyed before the body undergoes medical inspection. When the constriction of the neck is produced suddenly, and with great violence, we may expect to meet with it. This is found in the cases of executed criminals, and in strangulation attended with great violence, whether the act be due to homicide or suicide. In cases in which the constriction is gradually produced, the clenched state of the hands may not be found. Convulsions generally attend violent hanging or strangulation. The influence of these on the attitude of the body may not be apparent unless the body is sitting or lying down.

Internally, we meet with the appearances of asphyxia—i. e., engorgement of the lungs and venous system generally with dark-colored blood: the lungs otherwise present no particular appearance. In the case of an executed criminal, Dr. Massey, of Nottingham, found the lungs in a state of extreme collapse. ("Lancet," Nov. 9, 1867.) This is an unusual appearance. The right side of the heart, and the great vessels connected with it, are commonly distended with blood. But when inspection has been delayed for several days, this distension may not be observed. The mucous membrane of the windpipe is more or less

case in which there was a considerable effusion between the membranes. ("Lectures on Pathology," p. 58.) The venous congestion of the cerebral vessels is, however, rarely greater than in other cases of asphyxia, and is probably dependent on the degree in which the lungs have become engorged. In most instances there is increased redness of the substance of the brain, so that, on making a section of the hemispheres, a greater number of bloody points (*puncta cruenta*) than usual will appear. The kidneys have been found much congested. A more important circumstance has been noticed by Dr. Yellowly—namely, that in examining the stomachs of five criminals who had been hanged, he found great congestion in all, while there was blood coagulated upon the mucous membrane in two. Such an appearance might, it is obvious, be attributed in a suspicious case to the action of some irritant substance (p. 107, and "Ann. d'Hyg.," 1830, p. 166; 1835, p. 208; 1838, p. 471). In the case of *Good*, who was executed for murder some years since, the stomach was found on inspection to present over its whole surface a well-marked redness, resembling the effect produced by an irritant poison. The redness was especially observed at the pyloric end, where it assumed a somewhat striated character. A drawing representing the appearance of the interior of the stomach is preserved in the museum collection of Guy's Hospital. In a case examined by Mr. Stuart, of Azinghur, in 1854, the stomach and intestines, especially the inner coat of the former, were much congested and inflamed, as if the man had died from poisoning. The contents of the stomach were analyzed, but no poison was found. Dr. Chevers, who quotes this case, states that he has more than once verified Dr. Yellowly's observation, and has found the mucous membrane of the stomach much congested in death from hanging. ("Medical Jurisprudence for India," p. 397.)

The most striking external appearance, however, is the *mark* produced on the neck by the cord or ligature. The skin is commonly depressed, and sometimes ecchymosed, but rarely throughout its whole extent; it is frequently free from all traces of discoloration as the result of ecchymosis, the skin in the depression being then hard, brown, or of a *parchment color* and consistency; or there may be only a thin line of blue or livid color in the upper or lower border of the depression and chiefly in front. The course of the mark is generally oblique, being lower in the fore part than behind, and it is often interrupted. It is most commonly above the larynx. If the noose should happen to be in front, the mark may be circular, the jaw preventing the ligature from rising upwards in the same degree before, as it commonly does behind. The mark is generally single, but we may meet with it double, as when the ligature has been formed into two circles or loops previously to its application. Its other characters will depend upon the nature of the ligature employed. Thus a large and wide ligature rarely produces ecchymosis,—the mark is wide and superficial; but a small ligature produces a narrow and deep depression, sometimes accompanied with laceration of the cuticle and effusion of blood beneath the skin. The ligature or cord should always be examined for blood, hair, or other suspicious substances.

It was formerly believed that the mark on the skin produced by the cord was invariably discolored from effusion of blood, or ecchymosis; but

more correct observation has shown that this condition is an exception to the general rule. When ecchymosis does exist, it is commonly superficial and of slight extent. There is rarely, if ever, effusion of blood in the cellular tissue. In the bodies of persons who have been criminally executed, it is not unusual to find ecchymosis, but even here it is not always present, or only in front of the neck. Dr. Riecke, of Stuttgart, in his observations on hanging, found only once in thirty cases an effusion of blood beneath and on both sides of the depression produced by the ligature. The tongue was generally between the teeth, and in most cases wounded by them. He attributed death to stretching of the spinal marrow. (Henke's "Zeitschrift," 1840, 27 Erg. H. 332.) In a case which I had an opportunity of examining some years since, there was only a slight trace of ecchymosis in one spot where the knot in the cord had produced contusion. That it should occur in criminal executions is not surprising, considering the violence employed on these occasions, but it has been somewhat too hastily assumed that the appearances found in executed criminals, are met with in all cases of death from hanging. Dr. Croker King, in examining the neck of an executed criminal, did not discover the smallest effusion of blood in the course of the cord, although in this case the body had been allowed to fall from a height of seven feet and a half, with a fearful jerk. ("Dublin Quarterly Journal," No. 35, Aug. 1854, p. 86; and "Cases of Ruptured Intestine," 1855, p. 12.) The theory of the production of ecchymosis has been carried so far, that a *livid mark* in the course of the cord was formerly said to be the best criterion for distinguishing hanging in the living from hanging in the dead body! This statement, however, is not in accordance with facts. In a large number of cases the skin, instead of being blue or livid, or presenting an effusion of blood in the cellular tissue beneath, is hard and of a yellow color, resembling parchment. It has that appearance which the cutis commonly assumes when the cuticle has been removed from it two or three days; and, on dissecting it, the cellular membrane beneath often appears condensed and of a silvery whiteness. Dr. Chevers states that in cases of death from hanging he has not met with any ecchymosis in the skin along the course of the mark. (Op. cit., p. 406.) In some instances the mark has presented itself simply as a white depression; this has been chiefly observed in fat subjects. The observations of Casper on this point are as follows:—out of seventy-one cases there was no ecchymosis produced by the cord in fifty, and thus in two-thirds of all the cases examined, it was entirely absent. He also found that there was no difference in the appearance whether the ligature was removed sooner or later after death.

Injuries to the muscles and deep-seated parts of the neck are, of course, only likely to be seen when considerable violence has been used in hanging. It is now customary in criminal executions to give a long fall to the body, *i. e.*, from six to seven feet. Under these circumstances the muscles of the neck are found bruised and lacerated. The sterno-cleido-mastoid muscle has been found torn through, and its ends nearly two inches apart. In other instances the lining membrane of the common carotid artery has been found lacerated. Congestion and swelling of the genital organs of both sexes have been set down among the common con-

sequences of hanging,—but many observers have not met with these conditions; and it is doubtful whether, unless the body is examined speedily after suspension, any marked difference would be discovered. A more common sign, perhaps, is the discharge of the spermatic secretion in the male, by a spasmodic action, at the moment at which death takes place. It appears to me that no reliance can be placed upon evidence derivable from this appearance, and yet it has sufficed to give rise to a violent controversy among French medical jurists. (“Ann. d’Hyg.,” 1839, vol. 1, pp. 169, 467; vol. 2, p. 393; 1840, vol. 2, p. 314.) Unless death from hanging is strongly established by other facts, neither the examination of the linen of the deceased, nor the application of the microscope to the mucous fluid found in the urethra, would be of any practical value in elucidating the question,—at least to the satisfaction of an English jury. In a criminal execution which took place at Dublin, in which there was a fall of fourteen feet, the head was severed from the body! There was no dislocation of the vertebræ. The atlas was intact, but the axis was fractured. The blood flowed from the head in greater quantity than from the body. The carotid arteries continued to bleed at intervals for five minutes after death. (“Lancet,” 1871, vol. 1, p. 166; also vol. 2, p. 210.)

The following may be regarded as a summary of the appearances in hanging, when death has really taken place from asphyxia. The countenance is either livid or pale, the eyes are prominent, the tongue congested and occasionally protruded, the lower jaw retracted:—the skin is covered with patches of cadaveric lividity, the hands are livid and clenched,—an oblique mark is found on the neck, sometimes presenting traces of ecchymosis: commonly, however, the skin is only brown in color and hardened. The larynx, windpipe, and subjacent muscles are lacerated, depressed, or discolored. The vessels of the brain are congested, as well as those of the lungs and the right cavities of the heart. A mucous froth tinged with blood is occasionally found in the windpipe. These appearances will of course be modified, or they may be altogether absent, when death has arisen from disorder of the cerebral circulation, or from injury to the spinal marrow, either by great congestion, effusion of blood, fracture, or displacement.

Was death caused by hanging?—When a person is found dead and his body is suspended, it may be a question whether death really took place from hanging or not. In investigating a case of this kind, it is necessary to draw a distinction between the *external* and *internal* appearances of the body. The former alone can assist us in returning an answer to this question: the internal appearances of the body can furnish only the general signs of asphyxia, and enable us to say whether any latent cause of death existed or not.

The mark of the cord.—Among the external appearances, it is chiefly to the *mark* produced by the cord on the neck that medical jurists have looked for the determination of this question. As the form, position, and other characteristics of this mark have been already described, it will now be necessary to allude to it only as furnishing evidence of life at the time of its production. It has been stated, that so far from being constantly livid or ecchymosed, this condition is in reality not seen in more

than one-half of the cases which occur. But admitting that we find ecchymosis in the course of the ligature, are we always to infer that it must have been applied while the person was living? There are numerous cases which show that the presence of active life is not necessary for the production of ecchymosis in the mark; and from the experiments of Devergie, it would appear that if a body was hanged immediately or a short time *after death*, an ecchymosed mark may be produced on the neck by the ligature. (Op. cit., vol. 2, p. 408.) If a few hours were suffered to elapse, so that the body had become cold before suspension, no ecchymosis was produced by the ligature. Professor Vrolik, of Amsterdam, found, however, that a slightly livid mark was produced on the neck of a dead body, which had been suspended after the lapse of *an hour* from the time of death. (Casper, "Woch.," Feb. 1838.) Hence this condition of the mark in a body found dead merely indicates, either that the deceased must have been hanged while living, or very soon after the breath had left his body. It would be for a jury to decide between these two assumptions; and to consider why, when a man had really died from any other cause, his body should have been hanged in secrecy immediately after death. (See "Ann. d'Hyg.," 1842, vol. 1, p. 134.) The circumstance that an ecchymosed mark may be produced by suspending a recently dead body bears out the statement of Merzdorff—that it would be in the highest degree difficult, if not utterly impossible, to determine medically from an inspection, whether a man had been hanged while living, or whether he had been first suffocated, and his body suspended immediately after death. In making this admission, it is proper to bear in mind, that that which is difficult to a conscientious medical jurist in confining himself to the medical facts, is often easily decided by a jury from these as well as the general evidence afforded to them.

Sometimes, besides ecchymosis, there are abrasions of the skin in the course of the cord, and these are known to have been produced during life by the effusion of blood which accompanies them. Devergie never met with this appearance with the hanging of a dead body even when the hanging took place immediately after death. The discovery of effused coagula in or about the spinal column would render it probable that the deceased must have been hanged while living. Such marks of violence are, however, rare in cases of hanging; and when they are found, it might be assumed that the effusion and coagulation of blood had been caused by violence offered to the neck *immediately after death*; but this assumption may be met by the question already suggested—namely, why death by hanging should be simulated in the body of a person who is alleged to have died from another cause!

With regard to the other, or more common kind of mark in suicidal hanging, it can scarcely be said to furnish any evidence in relation to the question which we are here considering. The depression may be hard and brown, although it does not usually acquire this color until some hours have elapsed after death; for it appears to depend simply upon a desiccation or drying of that portion of the skin which has been compressed by the ligature. Sometimes the upper and lower borders only of the depression present a faint line of redness or lividity: and it is worthy of

remark that when the ligature presents any knots or irregularities, those portions of skin which sustain the greatest compression are white, while those which are uncompressed are found more or less ecchymosed. It is in this manner that the form of a ligature is sometimes accurately brought out. It may be remarked of these depressions produced by the cord, that the characters which they present are the same, whether the hanging has taken place during life or soon after death:—the appearances are similar in the two cases.

The experiments performed on dead bodies by Casper and other observers, show that the ordinary or non-ecchymosed mark caused by hanging during life, may be produced by a ligature applied to the neck of a subject *within two hours* or at a much longer period after death,—consequently the presence of this mark on the neck is no criterion whether the hanging took place during life or after death. The changes in the skin beneath the mark are also destitute of any distinctive characters: there is a similar condensation of the cellular membrane whether the hanging has occurred in the living or dead. These changes are the simple result of a physical cause,—mechanical compression.

Summary of medical evidence.—From the foregoing considerations we draw the conclusion that there is no special or distinctive sign by which the hanging of a *living* person can be determined from an inspection of the dead body. All the external marks may be simulated in a *dead* body, and the internal appearances furnish no characteristic evidence whatever. Still, when the greater number of the signs enumerated are present, and there is no other satisfactory cause to account for death, we have strong reason to presume that the deceased had died from hanging. We must not, however, abandon medical evidence on these occasions, merely because plausible objections may be taken to isolated portions of it. Facts may show that, however valid such objections may be in the abstract, they are wholly inapplicable in the concrete, *i. e.*, to the particular case under investigation. Perhaps the greatest medical difficulties occur in reference to cases of *suicide*, owing to the slight appearances which attend this form of death; but on these occasions, moral and circumstantial proofs are so generally forthcoming, that a medical inspection of the body is scarcely ever deemed necessary by a coroner. If, then, it is admitted by a medical jurist that it is not in all cases possible to distinguish hanging in the living from hanging in the dead, the admission must be considered as having reference to cases wherein persons destroy themselves, and not to cases in which they are destroyed by others. Even if a doubt were raised in any particular instance, it is more than probable that circumstantial evidence would furnish data for a decision, and thus satisfactorily make up for the want of strict medico-legal proofs. If when we found a deeply ecchymosed or livid mark around the neck of a dead subject, we said, all other circumstances being equal, that the person had most probably died by hanging, we should not be departing from a proper discharge of our duty; since, although it is medically possible that such a mark may, by a certain amount of skill, be produced after death, yet, as it would be only a murderer who would think of hanging up a recently dead body to simulate suicide, so it is certain that in this case there would be some obvious indications of another

that numerous cases of hanging during life would be pronounced cases of hanging after death, if the mere absence of ecchymosis mark were taken as a criterion. The discovery of marks of violence about the person is not of itself sufficient to rebut the presumption of death from hanging on these occasions. The violence should at least be of such a nature as to account for the immediate destruction of life; if it can throw no light upon the question whether the person might have died from hanging, in spite of the marks of maltreatment upon the dead body.

If, in reference to a body found hanging, a medical jurist should declare that death had *not* taken place from this cause, this would be tantamount to declaring that the deceased must have been murdered—because it is difficult to suppose that any one but a murderer would have a reasonable motive for hanging up a recently dead person. This hanging after death has been frequently carried out with the view of concealing the real cause of death, and of making the act appear to be one of suicide.

Marks of violence on the hanged.—The presence of marks of violence on the body of a hanged person is important, and it will, therefore, be proper for a witness to notice accurately their number, situation, and direction. Having satisfied himself that they must have been received during life, he will have to consider the probability of their being of accidental origin or not. These marks of violence are not to be regarded as furnishing unequivocal proofs of murder; it is possible that they may have been produced by the person himself while hanging, and not succeeding in committing suicide by these attempts, he may subsequently have resolved to accomplish his purpose by suspending himself. Let the witness duly reflect on these circumstances before he allows his opinion to implicate any suspected individual—let him consider that a hanged subject may bear the marks of a gunshot wound, his face may be cut, his person lacerated or disfigured, and yet, before a presumption of homicide is allowed to be entertained, it ought to be clearly established that such injuries could not, by any probability, have been self-inflicted. The importance of observing caution in such a case, will be still more manifest when there is no ecchymosis produced by the cord, and the

have had resolution enough to suspend himself again. Such an occurrence may be rare ; but when the presence of these injuries is made to form the chief ground of accusation against another person, their possibly accidental origin ought not to be lost sight of by a considerate witness.

The falling of the body on a hard pavement, or against some article of furniture, may produce accidental injuries which might be wrongly assigned to homicidal violence. In a case of suicidal hanging in the gaol of Newgate which occurred to Mr. Gibson, there was a copious effusion of blood from injuries produced accidentally after death. In death from asphyxia the blood remains fluid in the body longer than in other cases, so that accidental wounds after death, may be attended with comparatively large effusions. The bleeding *post-mortem* is also favored by the general congestion of the venous system. (Ann. d'Hyg., 1868, 2, 218.) Severe injuries may be found on the head of the deceased, and yet these may not be inconsistent with suicidal hanging. (See case by Dr. Riembault, "Ann. d'Hyg.," 1867, 1, 164 ; also, 1, 460.)

If we suppose the deceased to have been hanged in a state of intoxication or stupefaction, medical evidence alone will rarely suffice to determine the question of homicide or suicide. The absence of all marks of violence from the body might actually lull suspicion. It is proper on these occasions to look to the hands of the deceased, since it is with these that a person defends himself ; and unless taken unawares, it is almost certain, if the hanging were homicidal, that there would be traces of violence on these parts. The clothes would be torn and discomposed, and the whole appearance of the deceased would be that of one who had done his utmost to resist a violent murderous attack. There might be some injuries which could not be attributed to accident under the circumstances. Among these we may enumerate fractures, dislocations, deeply penetrating incised and gunshot wounds. Now the question is : Do these serious injuries necessarily establish homicidal hanging ? The answer must be in the negative ; although when fractures or dislocations exist, there are strong grounds for suspicion. ("Ann. d'Hyg.," 1842, vol. 1, p. 160.)

Suicides frequently make attempts on their lives by various means, as by poison, the use of razors, knives, or pistols, and still retain power to hang themselves. Such cases as these are generally determined by circumstantial evidence. A suicide may attempt to destroy himself with a knife or pistol ; he may fail in the attempt, and ultimately hang himself. Any description of wound, provided it be such as to allow of a person surviving a sufficient time, may thus be found on a hanged subject, and yet constitute no proof whatever of murder. If there are circumstances about the wound or injury which show that it could not have been self-inflicted, this of course will affect the conclusion ; but when such circumstances are not met with, a cautious medical jurist should say, in answer to inquiries respecting the origin of these wounds, that they may have been inflicted either by the deceased himself or by another. The medical facts of the case might be consistent with either view. In one instance of suicidal hanging there were lacerated wounds upon the head, and a handkerchief was found blocking up the mouth. A woman committed suicide in 1868 under the following circumstances :

She fastened a cord to the top of a bed-post, put her head in a noose while kneeling on the bed, and then made a deep wound in her arm with a razor; she closed the razor and put it aside. Becoming faint from loss of blood, she must have fallen forward, and the pressure of the cord on the neck caused death. Of course if, in any case, the wounds or injuries are of a decidedly mortal nature, and have probably caused death, the presumption of murder is very strong; for who but a murderer would suspend the dead body of a person so wounded *immediately* after death? ("Ann. d'Hyg.," 1835, vol. 2, p. 410.)

Was the hanging the result of accident, homicide, or suicide?—Most medical jurists have passed over the subject of *accidental hanging*, probably believing it to be impossible. In the sense commonly implied by the term it is certainly unusual, but although rare, it is a possible occurrence. Circumstantial evidence will always suffice for the discrimination of accidental hanging; and we have therefore merely to inquire whether, when the body of a person is found hanging under circumstances which do not allow of the suspicion of accident, the act has been the result of *suicide* or of *homicide*. A medical witness must remember that this is strictly a question for the jury. It is not for him to say whether a man has hanged himself or been hanged by others, but merely to state, when required, those *medical circumstances* which support or rebut one or the other presumption. The jury, under the direction of the judge, will arrive at a conclusion from the whole of the evidence, medical and non-medical.

Hanging is considered to be one of the most common forms of *suicide*. In England during five years (1863-7) 2570 persons thus destroyed themselves, four-fifths of whom were males. The next frequent form of suicide (cut throat) was represented in the same period by 1235 cases, while of drowning there were 1115 cases. Out of 6696 suicides, 4920, or nearly three-fourths, were committed in one of these ways.

It has been truly observed, that of all the forms of committing murder, hanging is one of the most difficult, and it is therefore but seldom resorted to. In most cases when a person has been hanged by others, it has been after death, in order to avert a suspicion of homicide. Hence the discovery of a person hanging affords *prima facie* evidence of suicide, supposing it to be rendered absolutely certain that death has taken place from this cause. We must, however, admit that a man may be murdered by hanging, and that the appearances about his body will not afford the smallest evidence of the fact. The circumstances which will justify a medical jurist in making this admission are the following: First, when the person hanged is feeble, and the assailant a strong, healthy man. Thus a child, a youth, a woman, or a person at any period of life, worn out and exhausted by disease or infirmity, may be destroyed by hanging. Secondly, when the person hanged, although usually strong and vigorous, is at the time in a state of intoxication, stupefied by narcotics, or exhausted by his attempts to defend himself. Thirdly, in all cases murder may be committed by hanging, when many are combined against one person. With these exceptions, then, a practitioner will be correct in deciding, in a suspected case, in favor of the presumption of suicide. Unless the person labored under stupefaction,

intoxication, or great bodily weakness, we must expect to find in homicidal hanging marks of violence about the body ; for there are few who would allow themselves to be murdered without offering some resistance, notwithstanding the assertion of Mahon, that some might submit to this mode of death with philosophical resignation when they saw that resistance was hopeless !

Some medical jurists have thought that the *mark* left by the cord on the neck, would serve as a criterion of murder on which we might depend. Thus it has been said, if the mark is circular and situated at the lower part of the neck, it is an unequivocal proof of murder. In hanging, the mark of the cord is generally oblique, being higher at the back part of the neck, in consequence of the loop formed by it yielding more in this direction than in front. But it is an error to suppose that this want of obliquity in the impression can afford any evidence in favor of the act having been homicidal. Its form will depend in a great degree upon the fact of the body being supported or not, for it is the weight of the body which causes its obliquity ; it will also depend on the manner in which the cord is adjusted. A case of suicidal hanging is related by Orfila, in which the mark of the cord extended horizontally round the neck from behind forwards. ("Méd. Lég.," tom. 2, p. 376.) The slip-knot of the cord was in front of the neck, and it is obvious that when the cord is thus adjusted by a suicide, there will be scarcely any obliquity in the depression produced by it. Equally ill-founded is the assertion that the existence of *two impressions* on the neck affords positive proof of homicide. One of these impressions may be at the lower part of the neck, and circular—the other at the upper part and oblique ; it is therefore contended that the deceased must have been strangled in the first instance and afterwards hanged. The possibility of a prior attempt being made by a suicide to strangle himself, and thus produce the mark, is not adverted to. "Si l'on observe les deux impressions," says Mahon, "l'assassinat est alors parfaitement prouvé." It is fortunate that there are facts on record to oppose to this very positive statement. One of the first cases reported by Esquirol is that of a female lunatic who committed suicide by hanging herself, and on whose neck two distinct impressions were seen—the one circular, the other oblique ! These appear to have arisen from the cord having been passed twice round the neck, the body being at the same time partially supported.

In some instances a presumption of homicidal interference may exist if there are two distinct impressions, but it cannot be admitted that they establish the fact of murder. Dr. Walter has reported a case of some interest in this respect. A woman was found hanging to the branch of a tree, the feet resting on the ground. There were two marks on the neck, one like that of strangling with the same ligature as that by which the body was hanging. Dr. Walter concluded that the mark produced by the suspension of the body was the result of post-mortem hanging after murder by strangulation. ("Vierteljahrsschrift," 1867, 1, 161.) In the same journal for 1871, 2, 223, a case is reported by Dr. Maschka, of Prague, in which a boy, æt. 9, was found hanging. There were on the neck marks of pressure, which at first led the examiners to draw the inference that the boy had been strangled and afterwards hanged. The

reasons for this opinion were not satisfactory, and suicide was admitted to be not only possible but probable.

The injury done to the neck by the cord or ligature can rarely afford any clue to the manner in which hanging took place, unless the circumstances under which the body is found, favor the presumption of homicide or suicide. Thus the laceration of the muscles and vessels of the neck, the rupture of the windpipe and the displacement of the larynx, the stretching of the ligaments of the spine, and effusion of blood on the sheath of the spinal marrow, may be observed in suicidal as in homicidal hanging. The presumption, however, is obviously in favor of the latter, when these violent injuries are found to be accompanied by fracture or displacement of the vertebrae of the neck, and the body of the deceased is not corpulent, the ligature by which he is suspended is not of a nature to produce them, and the fall of the body has not been great.

A much disputed question has arisen in medical jurisprudence, whether the vertebrae of the neck can become fractured or displaced in *suicidal* hanging. Most medical jurists deny the possibility of this accident occurring—the displacement or fracture of those vertebrae being rarely observed, even in criminal executions when the greatest violence has been used by the executioner. So far as I am aware, there is no case of *suicide* on record in which such an injury to the neck has been found.

Circumstantial evidence.—In all doubtful instances we should not lose sight of moral and circumstantial evidence. We should ascertain whether the individual had been previously disposed to commit suicide or not: we should observe whether the doors and windows of the apartments had been secured on the inside or on the outside; whether the dress of the deceased is at all torn or discomposed, or his hair dishevelled; whether the attitude of the body is such as to show interference after death; whether there are marks of blood about the body, or the ligature, or in the room; whether the hands are bloody, or present marks of wounding or struggling; whether the rope or ligature corresponds to the impression seen around the neck; and lastly, whether the cord is of sufficient strength to support the weight of the deceased. The strongest evidence of homicide is often found in the attitude and the state of the dress of the dead body: it may or may not indicate interference or change after death, irreconcilable with the supposition of death from suicide or accident. On this point the minutest circumstance may become of considerable importance as medical evidence. When there are indications of violent struggling, the dress may be found disordered, unless it has been smoothed or arranged by the murderer after the death of the deceased. There may, of course, be no evidence of disorder or discomposure of the dress in the case of a female, when the body is freely suspended. These points fall, it is true, more within the province of the officers of justice than of a medical practitioner; but the latter is generally the first who is called to see the deceased, and therefore, unless such facts are noticed by him on his visit, they may remain altogether unknown. The medical opinion of the actual cause of death, however, should be based only on *medical facts*, but circumstantial evidence has on various occasions assisted in clearing up a doubtful case. Louis states that on removing the body of a man who was found hanging, the rope was observed to be stained with blood.

This simple circumstance led to further investigation, by which it was discovered that the person had been murdered, and his body afterwards suspended. The presence of marks on the neck indicative of strangulation, such as the cord was not likely to have produced, may lead to a suspicion that the hanging followed death.

The position of the body.—Lastly, it has been contended that the position of the dead body may serve to distinguish suicidal from homicidal hanging. This point was strenuously argued on the investigation which took place relative to the death of the *Prince de Condé* in 1830. This case involves two glaring errors in reference to medical evidence in death from hanging: 1st, that a person cannot die from hanging when the body is in any way supported, and therefore that murder must have been perpetrated; 2dly, that in all cases of death from hanging, the mark produced on the neck by the cord or ligature must be discolored or ecchymosed. If not ecchymosed, it is assumed that death must have taken place from some other cause, and the body have been afterwards suspended for the concealment of crime. It is scarcely necessary to state that these propositions are utterly inconsistent with well-known facts. Since this trial, many cases have been recorded in which death has taken place from hanging, when the feet were in contact with the ground, or the persons were almost sitting or recumbent; they may be regarded as mixed cases of hanging and strangulation. The following case fell within my own knowledge: In 1832 a man was found hanging in his room, with his knees bent forwards, and his feet resting upon the floor. He had evidently been dead for some time, since cadaveric rigidity had already commenced. The manner in which this person had committed suicide was as follows: he had made a slip-knot with one end of his apron (he was a working mechanic), and having placed his neck in this he threw the other end of the apron over the top of the door, and shutting the door behind him he had succeeded in wedging it in firmly. At the same moment he had probably raised himself on tiptoe, and then allowed himself to fall; in this position he died. The weight of the body had already sufficed to drag down a part of the apron, for it seemed as if it had been very much stretched. The deceased was in the position in which the body of the *Prince de Condé* was found, and the depression produced by the ligature on the neck was, in that case, nowhere ecchymosed. These facts, so far from being considered to negative suicide, were treated as perfectly in accordance with it! Dr. Williams, of Norwich, communicated to me a similar case of suicide which occurred in September, 1872: A lady, who had been for some time suffering from great depression, was found dead, hanging by a long cloth to a closed door, over the top of which she had thrown the other end of the cloth (knotted) and then shut the door upon it. (For a similar case by Dr. Albert, see Henke's "Zeitschrift," 1843, 2, 50.) Casper reports an instance in which a man was charged with the murder of his wife because her body was found hanging in almost an erect position! ("Ger. Leich-Oeffn.," vol. 2, 92.) (For other cases, with illustrations of the positions of the body, see a paper by M. Tardieu, "Ann. d'Hyg.," 1870, 1, 94.)

In a case of suicide at Oxford, in September, 1876, the body of the deceased was found hanging behind the door of his bedroom. His

feet touched the ground and his knees were bent. A woman, æt. 62, confined in Clerkenwell prison in April, 1878, was soon afterwards found dead in her cell. The body was resting on the ground, suspended from a gas-pipe about four feet high, by a neckerchief round her throat. In January, 1877, Mr. Spenser, a barrister, was found dead in his bedroom under the following circumstances. He was in a sitting position on the floor, with the bell-pull, attached to the bed-post, tied around his neck. There was no doubt that this was an act of suicide. In another case of suicide, the subject of an inquest in 1878, a man was found dead suspended by a handkerchief to a cupboard door. When standing upright he was as high as the cupboard door, but after suspending himself he had drawn up his legs behind him, and had died asphyxiated in this singular position. In November, 1874, a lunatic who had escaped from his keepers was found hanging in a wood near Highgate to a sapling oak by a pocket handkerchief. The deceased was in a sitting posture, the tree being bent down by his weight.

The reports of eleven cases of suicidal hanging or strangulation which I collected within a few years, gave the following results: in three, the deceased were found nearly recumbent; in four, in a kneeling posture—the body being more or less supported by the legs, and in four, the persons were found sitting. In one case the deceased, a prisoner, was found hanging to the iron bar of the window of his prison, which was so low that he was almost in a sitting posture.

Romer found that among one hundred and one cases of suicidal hanging, in fourteen the body was either standing or kneeling, and in one instance it was in a sitting posture. Dr. Duchesne has published an account of fifty-eight cases in which the suspension of the body was partial—the feet or trunk being more or less supported. Twenty-six of these cases are new. The reporter draws the conclusion that *suicide* by hanging is consistent with *any posture* of the body, even when resting upon the two feet. ("Ann. d'Hyg.," Oct. 1845, vol. 2, pp. 141 and 346.) Further evidence need not be adduced to show how unfounded is that popular opinion which would attach the idea of homicidal interference to cases in which a body is loosely suspended, or in which the feet are in contact with any support. We ought rather to consider these facts as removing a suspicion of homicide; for there are probably few murderers who would suspend their victims, either living or dead, without taking care that the suspension was not partial but complete. Besides, the facts of many of these cases are readily explicable; thus, if the ligature is formed of yielding materials, or if it is only loosely attached, it will yield to the weight of the body after death, and allow the feet to touch the floor, which they might not have done in the first instance. If there is reason to believe that the body has not altered its position after suspension, we must remember the suddenness with which insensibility comes on, and the rapidity with which death takes place in this form of asphyxia. Under very slight pressure on the windpipe a person is rendered utterly powerless to help himself or to move from his position. (See p. 437, also "Med. Gaz.," vol. 44, p. 85.) In spite of these well-known facts, the most serious mistakes are still liable to be made. A case occurred in France in

June, 1872, in which a young man was charged with the murder of his brother, and suspending his body after death. The only grounds for this strong medical opinion were that there was no deep ecchymosed depression round the neck of the deceased, and the body was found hanging nearly in a sitting posture. These conditions were considered to be inconsistent with death from hanging. The cause of death was ascribed to poisoning with phosphorus, in consequence of some alkaline phosphates and phosphoric acid being found in the stomach by a chemical analysis! On this series of medical assumptions and mistakes, the young man, who had accidentally discovered his brother hanging, was convicted of murder, and sentenced to the galleys for twenty years! The ignorance displayed by the medical witnesses who gave evidence on this occasion has been fully exposed by MM. Boys de Loury, Chevallier, and Personne. (See "Ann. d'Hyg.," 1873, vol. 2, p. 113.)

The limbs secured in suicidal hanging.—One or two points are worthy of notice in relation to this medico-legal question. The hands or legs, but more commonly the former, have been found tied in cases of undoubted suicidal hanging ("Ann. d'Hyg." 1832, vol. 1, p. 419); and yet it has been gravely debated whether it was possible for a person to tie or bind up his hands, and afterwards hang himself! It is unnecessary to examine the ingenious arguments which have been urged against the possibility of an act of this kind being performed, since they are refuted by well-ascertained facts. ("Med. Gaz.," vol. 45, p. 388, and "Guy's Hospital Reports," Oct. 1851.)

It has also been a debated question, whether *corporeal infirmity*, or some peculiarity affecting the hands, might not interfere with the power of an individual to suspend himself. This question can be decided only by reference to the special circumstances of the case. In the case of the *Prince de Condé*, it was alleged that he could not have hanged himself, in consequence of a defect in the power of one hand; it was also said that he could not have made the knots in the handkerchiefs by which he was suspended. Allegations of this kind appear to have been too hastily made in this and other instances. A determined purpose will often make up for a great degree of corporeal infirmity; and unless we make full allowance for this in suicide, we shall always be exposed to error in drawing our conclusions. Blindness is no obstacle to this mode of perpetrating suicide; and in reference to *age*, suicide by hanging has been perpetrated by a boy of nine, and by a man of ninety-seven years of age.

[Some interesting observations and experiments with reference to the eyes of persons executed by hanging, were made at the execution of Anton Probst, by Dr. E. Dyer, of this city: "Fracture of the crystalline lens, as a result of death from violent hanging, has, I believe, never been noticed. The following case and experiments show that it is possible, and that it has probably been overlooked in many cases where post-mortem examinations have been made:—

"Anton Probst was hung in Philadelphia, June 8th, 1866, æt. 24. Weight, 174½ lbs. The drop was three feet; length of cord, five feet. There were no convulsions. Previous to the execution, both eyes were examined carefully with the ophthalmoscope, and were found normal. Thirty-five minutes after the drop fell, the eyes were again examined

with the ophthalmoscope by an electric light (charcoal points). In the right eye there was seen a horizontal line running across the lens; it was not sharp, but from it minute lines ran up and down, some longer and some shorter. It gave exactly the appearance of a crack in a clear cake of ice. As the eyeball was rolled downwards, it was evident that there was a crack or rupture in the crystalline lens, which extended from the anterior capsule backwards to the middle of the lens. It had a remarkable opalescent or iridescent appearance. The anterior capsule was ruptured. This fracture was about a line below the horizontal diameter of the lens. In the left eye the same appearances were observed, but in a less degree. The capsule was evidently ruptured, but the rupture of the lens-substance did not extend so deep. The eyes were removed and carefully dissected. All the observations made with the ophthalmoscope were entirely corroborated. The capsule of the right eye was broken from one edge of the lens to the other, and the lens itself was broken open to the centre. The left capsule was ruptured, and in the lens-substance the rupture extended about a line backwards.

“Three large dogs were hung in the following manner: The rope was adjusted around the neck and made fast to a cross-beam. A man held the dog up to the beam and let him fall, following him with his hands, and as the rope became taut, the force was continued by the man pressing the dog down with all his force. This added at least twenty pounds to the weight of the dog. All the dogs weighed over thirty pounds. Dog No. 1 died without struggles. Both lenses were fractured. Dog No. 2 died hard, and with convulsions which lasted 8–10 minutes. No lesion of either lens was observed. Dog No. 3 died with a few spasms. The right lens was fractured; the left was intact.

“It will be observed that one man and three dogs were hung—four subjects in all. In three out of the four, fracture of the lens was found. In two of the four, in both eyes, and in one in a single eye only. The fracture was most marked on the side opposite the knot. Of the eight eyes in these four subjects, five showed a fracture of the capsule of the lens, and the lens-substance itself in a greater or less degree. For a more detailed account of these cases, see ‘New York Medical Journal,’ vol. iii., and ‘Transactions of the American Ophthalmological Society,’ third year.”—P.]

[It is but proper to state that some experiments on dogs, subsequently conducted at the University of Pennsylvania, at the editor’s suggestion, have not verified Dr. Dyer’s results.—R.]

STRANGULATION.

CHAPTER XL.

CAUSE OF DEATH.—APPEARANCES AFTER DEATH.—WAS DEATH CAUSED BY STRANGULATION, OR WAS THE CONSTRICTION APPLIED TO THE NECK AFTER DEATH?—MARKS OF VIOLENCE.—ACCIDENTAL, HOMICIDAL, AND SUICIDAL STRANGULATION.

Cause of death. Asphyxia.—Hanging and strangulation are usually treated together, and some medical jurists have admitted no distinction in the meaning of these terms. In hanging, the phenomena of asphyxia take place in consequence of the *suspension* of the body, while in strangulation asphyxia may be induced not only by the *constriction* produced by a ligature round the neck, independently of suspension, but by the simple application of *pressure*, through the fingers or otherwise, on the windpipe. M. Tardieu considers that the two modes of death should be kept distinct. The external and internal appearances in some respects differ; and while the proof of death from hanging leads to the strongest presumption of suicide, the proof of death from strangulation is equally presumptive of murder. (*Sur la Strangulation*, “Ann. d’Hyg.” 1859, vol. 1, p. 107.) This medical jurist defines “strangulation to be an act of violence, in which constriction is applied directly to the neck, either around it or in the fore part, so as to prevent the passage of air, and thereby suddenly suspending respiration and life.” This definition obviously includes hanging, and every person who is hanged may be said to be strangled; but while there is only one method of producing death by hanging, there are various methods of producing death from strangulation. A person may be strangled by the use of a cord, band, or ligature drawn tightly round the neck, or by manual violence to the front of the neck, whereby respiration is prevented. The *cause* of death is asphyxia or apnoea. The rapidity with which it takes place will depend on the degree and situation of the pressure, and the completeness with which the act of breathing is obstructed.

M. Faure applied a ligature forcibly and suddenly to the neck of a middle-sized dog. For fifty-five seconds the animal did not appear to suffer; but he suddenly became violently agitated, his body stiffened, and he rolled convulsively on the ground. A bloody froth issued from his nostrils and throat, and he made frequent and violent efforts to breathe. In three minutes and a half he was dead. In a second experiment, an elastic tube was introduced into the windpipe, which admitted of being gradually closed by pressure. The animal could bear the pressure up to

the reduction of one-half of the calibre of the tube ; but beyond this he suffered greatly, and when the pressure was increased he had convulsions. The dog died, in great suffering, before the tube was completely closed. ("Ann. d'Hyg.," 1859, vol. 1, p. 122.) It is probable that human beings die more quickly than animals, especially from the effects of manual strangulation. A sudden and violent compression of the windpipe renders a person powerless to call for assistance and give alarm, and it causes almost immediate insensibility and death, without convulsions. When a ligature or bandage is used, the pressure is not so complete, and death takes place more slowly, with convulsive movements. The circulation of dark-colored blood continues for a short interval (about four minutes), as in other cases of asphyxia. Owing to this, the face and lips in accidental strangulation, have been observed to acquire a dark-leaden hue. This arises partly from the arrest of the current of venous blood as the result of compression of the vessels, and partly from the circulation of unaërated blood. There is a fair chance of recovery if the cause of constriction is removed, and air is permitted to have access to the lungs within a period of five minutes : this is on the assumption that no great mechanical injury has been done to the neck. In the act of strangulation a much greater degree of violence is commonly employed than is necessary to cause death ; and hence the marks produced on the skin of the neck will be, generally speaking, much more evident than in hanging, where the mere weight of the body is the medium by which the windpipe is compressed.

Post-mortem appearances.—The appearances after death are similar to those of hanging, but the injury done to the parts about the neck is commonly greater. *Externally.*—If much force has been used in producing the constriction, the windpipe with the muscles and vessels in the fore part of the neck may be found cut or lacerated, and the vertebræ of the neck may be fractured. The face is commonly livid and swollen, the eyes wide open, prominent, and congested, and the pupils are dilated. The tongue is swollen, dark-colored, and protruded : it is sometimes bitten by the teeth, and a bloody froth escapes from the mouth and nostrils. The principal external signs of strangulation are seen in the marks on the neck, produced either by a cord or manual pressure. M. Tardieu has described another appearance which might be overlooked. This consists in the presence of numerous small spots of ecchymosis upon the skin of the face, neck, and chest, as well as in the conjunctivæ or membranes of the eyes. These parts present a dotted redness, which has, however, been met with in other cases besides death from strangulation. ("Ann. d'Hyg.," 1859, vol. 1, p. 125.)

The mark on the neck when a ligature has been used, is commonly described as a depression, wide but not deep, and corresponding in its characters to the form and thickness of the ligature and the mode in which it has been secured. Too much importance must not be attached to this supposed correspondence when the ligature is not forthcoming. In a case of accidental strangulation which I saw in November, 1864, the mark round the neck presented the appearance which might be expected from the use of a narrow cord. But, in this instance a soft silk neckerchief was the means of constriction, and the peculiar narrowness

of the mark on one side was owing to the great tightness with which it had been drawn. The mark or impression produced by a ligature is generally circular, from the mode in which the pressure is produced. It may be situated at any part of the neck, but it is more commonly below the windpipe. In manual strangulation the marks of bruising and ecchymosis will be in the front of the neck, chiefly about the larynx and below it. The circular direction of a mark produced by the ligature is not an absolute indication that strangulation has taken place without suspension of the body, since cases of hanging have occurred in which a circular mark has been observed; and it is possible that some degree of obliquity may occasionally exist in the course of the depression produced by a ligature in strangulation. A medical jurist ought, therefore, to weigh all the facts connected with the position of the body and the nature and direction of the ligature, before he forms an opinion from the appearances presented by the mark on the neck, whether the person has been hanged or not. Greater importance is to be attached to the lividity, ecchymosis and abrasion of the skin in the course of the ligature, than to the circularity or obliquity of the depression produced by it. In the strangling of a living person by a cord, it is scarcely possible that a murderer can avoid producing on the neck marks of severe injury, and in the existence of these, we have evidence of the violent manner in which death has taken place.

In cases in which great violence has been used to the neck, blood may escape from the mouth and nose. It is a matter of popular belief that if there is no open wound in the body there can be no bleeding. In *Reg. v. Millar*, C. C. C., July, 1870, the prisoner was charged with the murder of a Mr. Huelin. One of the circumstances which led to the discovery of the crime was the large amount of blood which had escaped from the mouth and nose as a result of the act of strangulation. The evidence left it clear that the prisoner had murdered Mr. Huelin and his housekeeper, and had endeavored to conceal the dead bodies. He had packed the body of the housekeeper in a box, and requested a carrier to place a cord round it. The man observed that fluid blood was oozing from the box, and that there was a large stain of blood on the floor beneath. On opening the box, the body of the woman was found inside. There was a cord tied tightly round the neck of the deceased, and blood had escaped from the mouth and nose and had run down the side of the box. The deceased had been strangled, and such an amount of force used in the tightening of the cord round the neck, as to lead to a copious effusion of blood from the mouth and nose. In cases of asphyxia, as it has been elsewhere stated, the blood, owing to its liquidity, continues to flow for some time after death from any lacerated wound or bloodvessel.

On the other hand, a person may be strangled, and yet the ligature, in consequence of its being soft and of a yielding nature, will not cause a perceptible depression or ecchymosis—scarcely anything more than a slight depression of the skin. If we except cases of suicide, such a condition must be rare; because assailants usually produce a much more violent constriction of the neck than is necessary to ensure the death of a person. The general lividity of the body, contraction of the fingers, with clenching of the hands and swelling and protrusion of the tongue,

are more marked in strangulation than in hanging. A thin mucous froth tinged with blood is occasionally found in the air-passages in both cases. In some instances of violent strangulation, blood has escaped from one or both ears during the act; but this is not a usual appearance. In two well marked cases, in which I was consulted, the constriction of the neck was carried to a great degree, but there was no bleeding from the ears. The late Dr. Geoghegan informed me that in a case of *suicidal* strangulation which he examined, the constriction had been produced by a riband, and the violence applied was sufficient to produce bleeding from one ear; on dissection this was found to have resulted from a rupture of the membrane of the drum of the ear. There was no froth at the mouth or nostrils, and scarcely any lividity or swelling of the face. It was further observed that the mark on the neck, which was deep, almost disappeared after the removal of the ligature. Sir W. Wilde, of Dublin, met with a case in which rupture of the membrane of the drum of the ear with effusion of blood, was caused by strangulation. Bleeding from the ears, as a result of rupture of the membrane of the drum, must, however, be regarded as an exceptional appearance. Dr. Chevers does not mention it as having been noticed in any one of the numerous cases which he has collected in his Indian experience, although bleeding from the nostrils had been observed. ("Med. Jur. for India," 1856, p. 374.) Without rupture of the membrane of the drum, blood could not issue from the ears, and in order that this membrane should be ruptured, certain conditions not commonly met with are required.

Internally. In a case which occurred to Dr. Fuller of Nuldea, the body of a woman who had been homicidally strangled, presented the following appearances. The skin of the head, face, neck, and chest was darker than natural and discolored underneath, particularly that of the scalp. The brain was suffused with dark blood, the lungs gorged and of a dark color, the bowels of a dusky-red color. The eyes were somewhat protruded and bloodshot, the lips swollen and darker than natural, the tongue slightly protruding between the teeth, and froth issuing from the nostrils. There was a mark of pressure behind the right ear, and other marks on the neck and chest, with discoloration of the muscles. (Chevers's "Medical Jurisprudence for India," p. 378; see also p. 437.) In a case of suicidal strangulation which occurred at Liverpool in 1863, the body of the deceased was found dead, cold, and rigid, about seven hours after he had been seen alive. The arms were flexed, and the hands raised a little above the breast. Round the neck, just below the cricoid cartilage, was a strip of the deceased's shirt, which had been used as a ligature; it was tied at the *back* of the neck. There was slight ecchymosis in the mark beneath. The skin of the face had a dark-red color, and was dotted with spots of a deeper red. The conjunctivæ were ecchymosed, and some blood had escaped from the nose. The brain was congested, and much fluid effused. The heart was empty: the lungs were deep in color (congested). ("Lancet," Aug. 15, 1863, p. 183.) Many of the cases of strangulation which have presented themselves, have been too superficially examined. The most complete account of the appearances is that given by M. Tardieu. It is based on observations made in twenty-eight inspections. ("Ann. d'Hyg.," 1859, vol. 1, p. 132.) The lining mem-

brane of the larynx and windpipe was more or less reddened from congestion,—sometimes it was livid or of a dark-red color. There was a bloody froth extending into the air-tubes. The state of the *lungs* was variable. Contrary to what is generally alleged to be characteristic of death by asphyxia, M. Tardieu found these organs to contain but little blood. Sometimes they were congested, at other times normal. There were ruptures of the superficial air-cells producing patches of emphysema, which were seen singly or in groups. This condition, which was rarely absent, gave to the surface of the lungs the appearance of being covered with white layers of thin false membrane. When these patches were punctured, air escaped. There was an absence of that condition of the lungs which he observed in death from simple suffocation, namely, dotted ecchymosis on the surface, immediately below the investing membrane (the pleura). Throughout the substance of the lungs, effusions of blood varying in size were, however, generally found, provided an early inspection of the body was made. When some days had elapsed, the lungs were found pale or congested, without any ecchymosed or mottled appearance. The ruptured air-cells with air beneath them, were still visible on the surface.

The *heart* presents no uniform condition: it is sometimes quite empty, and at others it contains dark fluid blood. The *brain* is occasionally congested, but more commonly in its natural state. In one instance blood was found effused on the brain, but this is an unusual appearance. It has also been stated that a congested state of the sexual organs, both in males and females, was one of the appearances connected with strangulation, but this has not been confirmed by careful observers. M. Tardieu met with nothing to call for notice in this respect in the numerous cases which he examined. The involuntary discharge of feces, urine, and seminal fluid, described as one of the characters of death by hanging, may equally occur in death from strangulation. No importance can be attached to this as a sign of death from asphyxia in any form. It frequently occurs in sudden and violent death from any cause, and there are many instances of death from asphyxia in which it is not observed. Among the occasional appearances of violent strangulation, may be mentioned injury to the windpipe and the muscles of the neck around it. One case in which the rings of the windpipe were split as a result of pressure, was communicated to me by Dr. Inman, of Liverpool. Several instances of laceration and rupture of the windpipe are quoted by Dr. Chevers. (Op. cit., pp. 381, 384.) In one instance the ossified thyroid cartilage had been broken and forced inwards, causing suffocation. In *Reg. v. O'Brien* (Liverpool Winter Assizes, 1857), a case of alleged murder by strangulation, the cartilage of the windpipe was broken; and in the case of *Pinckard* (Northampton Lent Ass., 1852), the windpipe was broken longitudinally. In reference to fractures of the larynx, see Casper, "Klinische Novellen," 1863, p. 497. In suspected homicidal strangulation it is always proper to examine the contents of the stomach for narcotic poison. In all cases, the cord or ligature, if forthcoming, should be carefully examined, in order to determine whether it bears upon it marks of blood, or whether hair or other substances are adhering to it. A portion of it should be reserved for the purposes of identity. In two

instances of homicidal strangulation, the ligatures found round the dead bodies were proved to correspond with portions of the same material found in the possession of the persons who were charged with the murders. In removing the ligature from the neck, the precise mode in which it is tied or secured should be noticed, as this may be a fact of importance in reference to an allegation of suicide.

The medico-legal questions relative to strangulation are of the same nature as those which have been already considered in treating of hanging. Thus, in examining the body of a person suspected to have been strangled, we may be required to answer the following questions:—

Was death caused by strangulation, or was the constricting force applied to the neck after death?—Medical jurists have hitherto considered that the *internal* appearances throw no light upon this question. This opinion probably arose from the fact that inspections have not been made until some days after death, when the peculiar appearances of strangulation have been merged in those of putrefaction. The state of the lungs, however, may be considered as characteristic. It would be impossible, by the application of a ligature round the neck of a dead body, to produce rupture of the air-cells on the surface of the lungs, and effusions of blood in their substance. The state of the eyes and of the inside of the larynx and windpipe in persons who have been strangled could not be imitated by any constriction of the neck after death: no bloody mucous froth would be found in the windpipe or air-tubes. The *external* appearances have been considered to furnish more accurate means of distinction. Although the condition of the neck generally yields the strongest evidence, it will be proper to seek for that appearance of dotted redness or ecchymosis in the skin of the face, neck, and chest, described by Tardieu. The state of the eyes, as to their prominence and the congestion of the membranes, as well as the position of the tongue, should also be examined. The ecchymosis about the depression of the neck, when a ligature has been employed, with the accompanying swelling and lividity of the face, are phenomena not likely to be simulated in a dead body by the application of any degree of violence. When the constriction is produced within a few minutes after death, an ecchymosed depression may result; but it is improbable that there should be any lividity or swelling of the countenance. Prof. Casper found that when the constricting force was not applied to the neck until *six hours* after death, a mark indicative of vital strangulation could *not* be produced. It is doubtful whether it could be produced in the dead body even an hour after death. The period cannot be determined with positive certainty: the results would probably vary, according to the rapidity with which the body had cooled.

This question was of importance in the case of *Marguerite Dirlanc*, tried in June, 1872, at the C. C. C. for the murder of her mistress, *Madame Riel*. The body of deceased was found with marks of violence about the head, sufficient to account for death, and there was a rope tightly drawn round the neck. In the defence it was suggested that the rope had been placed round the neck after death for the purpose of dragging the body to the place where it was found. Another theory was that the prisoner had strangled her mistress with the rope. From the appearance of the neck, the medical evidence left it doubtful whether the rope

had been applied during life or soon after death. If the former it would have proved a deliberate design to murder. The prisoner received the benefit of the doubt, and although found guilty, the capital sentence was commuted.

It is difficult to conceive under what circumstances an attempt to simulate strangulation in a recently dead body could be made, unless for the purpose of throwing suspicion upon an innocent person connected with the deceased. When an individual has been murdered, it is not likely that the murderer would attempt to produce the appearances of strangulation on a body after death, under the idea of concealing his crime; for strangulation is, in most cases, an actual result of homicide, and is rarely seen as an act of suicide. A rope might, however, be applied, as in Dixblanc's case, *supra*, for the purpose of dragging the body. In the absence of ecchymosis from the neck it will be difficult to form an opinion, unless from circumstantial evidence; but there may not be an ecchymosed *circle*; for a person may be strangled by the application of pressure to the windpipe through the medium of the finger-nails, or of any hard or resisting substance. The ecchymosis on the neck in such cases will be in detached *spots* or *patches*. In the absence of all marks of violence round the neck, we should be cautious in giving an opinion which may affect the life of an accused party; for it is not probable that homicidal strangulation could be accomplished without the production of some appearances of violence on the skin over the larynx or windpipe. It is doubtful whether strangulation can ever take place without some mark being found on the neck indicative of the means used. The bare possibility of death being caused in this manner, without leaving any appreciable trace of violence, must be admitted; although the admission scarcely applies to those cases which require medico-legal investigation. Suicides and murderers generally employ much more violence than is necessary for the purpose of destruction—hence detection is easy. But if a soft and elastic band were applied to the neck with a gradually regulated force, it is possible that a person might die strangled, without any external sign being discovered to indicate the manner of his death. Indian surgeons inform us that the Thugs, and other robbers met with in India, are thus accustomed to destroy their victims with the dexterity of practised murderers.

A case involving this question of strangulation without marks of violence on the neck, was tried in France, and from the medical evidence decided in the affirmative. ("Gaz. Méd.," 9 Mai, 1846, p. 375.) The medical witness should, however, be prepared to consider whether, in the absence of any mark, death might not have proceeded from another cause, and leave it to the authorities of the law to decide from circumstances, in favor of or against the prisoner. There is, I conceive, nothing to justify a medical witness in stating that death has proceeded from strangulation, if there should be no appearance of lividity, ecchymosis, or other violence about the neck or face of the deceased. Congestion in the organs of generation is an appearance which it would not be safe to take as positive evidence of death from strangulation. The state of the countenance will not warrant the expression of an opinion, unless it is accompanied by other well-marked signs of this mode of death; for there

are many kinds of death in which the features may become livid and distorted from causes totally unconnected with the application of external violence to the throat. So, again, the eyes and tongue may be protruded as a result of putrefactive changes. Let not a witness, then, lend himself as an instrument for the condemnation of a person against whom nothing but a strong suspicion from circumstances may be raised, and where medical evidence is unable to furnish any distinct and conclusive proofs of death from strangulation. This caution is especially necessary in reference to the inspection of bodies which are in a state of putrefaction. A medical man, already provided with a theory of the cause of death by the discovery of a rope or other means of constriction, found near a dead body, may easily arrive at the conclusion that death has taken place from strangulation. The absence of the usual confirmatory appearances in the body may be ascribed to decomposition, and those caused by decomposition may be set down to strangulation. Where there is obvious mechanical violence to the neck, such as fracture of the larynx or windpipe, with laceration of the muscles beneath—a visible depression, such as a cord, a ligature, or manual pressure would produce, a medical opinion may be fairly given in spite of putrefaction. But when, in a putrefied body, indistinct marks on the neck, or patches of discoloration, are relied upon as evidence of homicide, there is great risk of a serious medical mistake.

In cases of alleged drowning, it is sometimes the practice to ask a medical witness how far his opinion of the cause of death has been influenced by the discovery of the dead body in or near water. In cases of alleged strangulation, a similar question may be put in reference to the discovery of a rope or ligature round the neck of the deceased, or in the apartment in which a dead body is found. A medical opinion should rest upon the clear and obvious changes produced on the neck, and on the structures below the skin, and not upon the mere presence of a cord or ligature. This might be put round the neck of a dead body, or near to it, for a malicious purpose. The act of strangulation should be, medically speaking, as distinctly provable without the production of a rope, as the act of stabbing without the production of the knife which inflicted the stab. If these principles are not strictly adhered to in practice, policemen will be as competent as medical experts, to give evidence of the cause of death in cases of alleged strangulation.

It is scarcely necessary to state that all marks of violence on the body of a supposed strangled person should be accurately noted, as the questions respecting them, however slight the marks may be, are material. The witness will be expected to state whether they were inflicted before or after death; if before, whether they were sufficient to account for death, or whether they were such as to be explicable on the supposition of an accidental, suicidal, or homicidal origin. It should be observed whether there exist any morbid changes sufficient to account for death, in either of the three great cavities of the body, as this kind of negative evidence may be essential in the progress of a case. In reference to females, whether children or adults, the surgeon should not neglect to examine the sexual organs in order to ascertain whether there are any marks of violation. Cases have occurred in which rape has been

perpetrated, and strangulation resorted to for the purpose of concealing the crime.

Strangulation, like hanging, is occasionally the result of *accident*, but the occurrence may be looked upon as rare. When the body is not suspended, it is commonly more in the power of a person to assist himself, and escape from the constriction: hence cases of accidental strangulation are less frequent than those of accidental hanging. As a general rule, cases in which the constriction of the neck has been produced by some accident, present no difficulty to a medical jurist, provided the relations of the body to surrounding objects and the compressing force have not been disturbed. Should it happen, however, that the body has been removed from the place in which it was first discovered, or the ligature taken from the neck, we can only establish a presumption of accident from the description given.

When a charge of murder is instituted against a person, an attempt is not unfrequently made by counsel for the defence to show the probability that the deceased might have fallen while in a state of intoxication, and have become accidentally strangled, either by a tight cravat or by some foreign substance exerting pressure on the windpipe. If we admit the possibility of an occurrence of this nature, we must not lose sight of the existence of other more probable causes of death, nor should we allow our judgment to be so swayed as to abandon what is probable for that which is merely possible.

Suicidal strangulation.—This mode of suicide is of rare occurrence, and, except under particular circumstances, impossible. The possibility of an individual strangling himself was for a long time denied by medical jurists; for it was presumed that when the force was applied by the hand, all power would be lost as soon as the compression of the windpipe commenced. This reasoning, which is physiologically correct, is, however, only applicable to those cases in which the windpipe is voluntarily compressed by the fingers. When a person determined on suicide allows the windpipe to be compressed, by leaning with the whole weight of his body on a cord passed round his neck and attached to a fixed point, he may perish in this manner almost as readily as if he had hanged himself; for insensibility and death will soon supervene. In the chapter on Hanging, it was stated that suicides were often found with their bodies in close contact with the ground; and cases are reported in which strangulation was accomplished, in the manner above described, while the suicide was in a sitting or kneeling posture (p. 437). On other occasions, the peculiar disposition or nature of the ligature has enabled a person bent on suicide to strangle himself without much difficulty. An instance is related by Orfila, in which two cravats, that were twisted several times round the neck of the deceased, who was discovered lying on his bed, had effectually served the purpose of self-destruction. (“*Mé. Lég.*,” vol. 2, p. 389.) Sometimes strangulation has been suicidally effected by a rough cord passed repeatedly round the neck, and tightened by being pulled with each hand. The number of coils would still cause some pressure to be exerted even when the grasp was relaxed by death. (See “*Guy’s Hospital Reports*,” Oct. 1851.) Other cases are related, in which suicides have succeeded in strangling themselves by tightening

the ligature with a stick (see "Guy's Hospital Reports," Oct. 1851); or when the ligature was formed of thick and rough materials, by simply tying it in a knot.

In a case communicated to me in 1874 by Dr. Mackintosh, of Downham, a youth was found dead in a field with the handle of a pitchfork passed under the necktie. There were marks of strangulation on the larynx, the eyeballs protruded as well as the tongue, which was livid and marked by the teeth. The brain was full of fluid venous blood. There was no doubt that death had taken place by strangulation, probably suicidal, as it is difficult to conceive that the handle of the fork could have come by any accident into the position in which it was found. A case occurred at Pentonville in December, 1875, in which a man was found dead in bed, with his handkerchief tied round his neck and twisted from right to left by means of a razor-strop. There was no doubt that this was a case of suicidal strangulation.

Although suicidal strangulation may be effected under unexpected circumstances, yet in a case of murder by strangulation, it would not be easy to simulate suicide: it would at any rate require great skill and premeditated contrivance on the part of a murderer, so to dispose the body of his victim, or to place it in such a relation to surrounding objects, as to render a suspicion of suicide even probable. Thus, if the cord or ligature should be found loose or detached,—if the ecchymosis or mark in the neck should not accurately correspond to the points of greatest pressure,—if, moreover, the means of compression were not evident when the body was first discovered and before it had been removed from its situation, there would be fair grounds for presuming that the act was homicidal. In those cases in which strangulation has resulted from a compression of the windpipe by the fingers, and where there are fixed ecchymosed marks indicative of direct manual violence, we have the strongest presumptive evidence of murder; for neither accident nor suicide could be urged as affording a satisfactory explanation of their presence.

Dr. Hofmann, of Innsbruck, met with an instance of this kind in which he rightly concluded, from the deep depressions in the neck of the deceased, attended with abrasion of the cuticle and effusion of blood, as well as from the great injury done to the parts about the larynx and trachea, that the strangulation was homicidal. (Eulenberg's "*Vierteljahrsschrift*," 1873, 2, p. 89.) This case is remarkable for another fact. The assassin had wiped his hand, which must have been stained with blood from the violence used, on a towel which was found concealed, but was subsequently traced to his possession. It was affirmed in defence that the blood on the towel was of old date, but spectral analysis showed that it had the characters of recent blood. That this had been used for the purpose stated, was proved by the discovery on it of the shreds of epidermis and the fine downy hairs of the deceased such as would have been removed under violent pressure with the fingers. The same medical jurist met with a remarkable case of suicidal strangulation. A woman was found dead with her head immersed in a bath, and a cord or string thrice wound round her neck. The post-mortem appearances are minutely described. The most important fact in the case was the position

of the body ("Ann. d'Hygiene," Dec. 1879, p. 529). Mr. Williams, of Norwich, communicated to me the following singular case, which occurred in July 1879. A gamekeeper, æt. 29, whose mind had been unsound, was found dead from strangulation. There was no doubt that this was an act of suicide. He had twisted a fishing net firmly round and round his neck, until it was firmly held in its position so that it required no knot to secure it. In this state he died.

Homicidal strangulation.—Strangulation occasionally comes before our courts as a question of murder: and when a person has been tried upon a charge of this kind, the circumstances have been commonly so clear as to render the duty of a medical witness one of a simple nature. When the cause of death is contested, or when it is contended in defence that the strangulation is suicidal, a medical witness must be prepared to give his reasons for affirming that the act was not done by the deceased himself. He must be prepared to meet and explain the differences between the case under investigation, and those reported cases which are admitted to have been suicidal. The attitude of the body, the condition of the dress, the means of strangulation, the presence of marks of violence or of blood on the person of the deceased,—on his clothes or the furniture of the room, or on the rope or ligature, are circumstances from which, if observed at the time, important medical inferences may be drawn. As a rule, a criminal who attempts to imitate suicide under such a form of murder must, when the facts are properly investigated, inevitably fail in his object. The assassin either does too little, or he does too much. In one case of murder by strangulation, the woman who perpetrated the crime had been a nurse in an infirmary, and accustomed to lay out dead bodies. After the act of murder she appears to have carried out, unthinkingly, her professional practice, by smoothing the clothes under the body, placing the legs at full length, the arms out, straight by the side, and the hands open and laid out! Such a condition of the body was quite inexplicable on the supposition of suicide, considering the amount of violence which must have attended the strangulation. In another case, the criminal had attempted to make the death appear like an act of suicide by placing the lower end of the rope near the hand of the deceased: but he selected the *left* hand, whereas the deceased was right-handed, and he did not leave enough rope free from the neck for either hand to grasp, in order to produce the very violent constriction of the neck which had been caused by the two inner coils. Both of these criminals confessed their crimes before execution.

Sometimes the appearance of the *mark* on the neck will allow us to establish a slight presumption for or against homicide. In homicidal strangulation, from the unnecessary violence used, we may expect to find the skin ecchymosed, lacerated, or excoriated; and the deep-seated parts, such as the muscles and vessels, as well as the windpipe itself, more or less bruised, lacerated, or extensively injured. Such a degree of violence is not commonly observed in cases of *suicidal* strangulation. Fracture of the os hyoides larynx and trachea generally indicate an amount of violence inconsistent with suicide. In *Reg. v. Woodford* (Lewes Spring Ass., 1876), a case of alleged murder by strangulation, the medical evidence showed not only the marks of a thumb and fingers,

as if the deceased had been seized by the throat, but the os hyoides was found fractured at a spot corresponding to a mark on the throat. There was no doubt that these were the results of homicidal violence, and the prisoner was convicted.

In *Reg. v. Perryman* (C. C. C., April, 1879) the prisoner was charged with the murder of his mother by strangulation. The prisoner and deceased, a woman æt. 70, were heard quarrelling in a room. On entering the room, deceased was found lying on the bed quite dead, and a medical man who was called in pronounced that death had been caused by strangulation. A handkerchief with a large knot in it was found lying by the side of the deceased. This handkerchief appeared to have been tied tightly round the neck of the woman, as this exhibited a deeply indented mark extending round the neck, which had evidently been produced by a strong hand. These facts were considered inconsistent with an act of suicide, and the prisoner was convicted and sentenced to penal servitude for life.

A case of some importance occurred at Lisbon in 1876. It was suspected that an Englishman had been murdered and his body secretly buried. In March, 1877, seven months after death, the body was exhumed, and a medico-legal examination made by three eminent professors of the University, Manuel Bento de Souza, José Thomaz de Souza, J. C. de Cumara Caboul. The principal appearances found were: Effusions of blood, with sub-pleural ecchymoses in the right lung; general congestion of the smaller vessels; the mucous membrane of the trachea reddened. The larynx presented marks of serious mechanical injury. The fore part of the cricoid cartilage had been torn through, and there was displacement of and injury to the thyroid cartilage. The first rib on each side was broken, and the second rib on the left side was also broken in two different places. These appearances clearly showed that great violence had been applied to the chest and trachea, and pointed to death by manual strangulation. This case was at the time considered of such importance, that as different medical opinions had been given by Portuguese professors, a report of the facts was remitted for consideration to all the medical jurists of Europe. The greater number agreed in the view that neither accident nor suicide would account for the appearances, and thus the only justifiable inference from them was, that the deceased had died from asphyxia as a result of violent strangulation by manual force applied to the neck. Pressure simultaneously applied to the chest may have caused fractures of the ribs, and have accelerated death. (The medico-legal reports in this case formed a complete volume in all the languages of Europe.)

The mark on the neck has sometimes furnished evidence of this mode of death, even under circumstances in which it might be supposed all evidence would be destroyed. Dr. Schuppel, of Tübingen, describes a case in which he was able to verify the fact of strangulation after the burning of the body. In August, 1869, a fire took place in a cottage in which there were at the time a man and his wife with a stepson (æt. 10) and a new-born infant. The man escaped with the infant, and said that his wife and stepson had left the house before the fire. This was proved to be a falsehood; their dead bodies were subsequently discov-

ered much burnt. A suspicion of incendiarism and murder arose, and the remains were examined by Dr. Schüppel. On the burnt remains of the neck of the boy there was a horizontal mark or depression encircling the greater part of the neck, about one-quarter of an inch wide, and presenting a smooth surface, quite distinct from the broken, blistered, and carbonized skin above and below it, and the tongue protruded from the mouth.

From this condition of the neck and tongue Dr. Schüppel drew the conclusion that the boy had died from strangulation, and that the ligature had been applied to the neck while the boy was living, and had been burnt with the body. (Horn's "*Vierteljahrsschrift*," 1870, 2, 140.) The man was found guilty of the murder of his wife and stepson, and a few days afterwards he committed suicide by hanging himself while in prison. He had set fire to the house after the murder, in order to conceal this double crime. The burnt neck of the boy, with the mark upon it, is preserved in the Museum of the University of Tübingen.

In *Reg. v. Lunnum* (Warwick Lent Ass., 1873), a woman was charged with the murder of her child, a month old, by strangulation. There were five marks on the throat, such as would be produced by the pressure of four fingers and a thumb. These were quite recent. The prisoner stated that these marks were produced by her a fortnight previously, in trying to get a button out of the child's throat. They were too recent to admit of this explanation, and she was convicted of manslaughter. In the case of the *Countess of Goerlitz* (*ante*, p. 412), whose body was destroyed by burning, the tongue protruded from the mouth, thus indicating death by strangulation. In a case which occurred to Mr. Jackson, of Grantham, some of the appearances of strangulation were found in spite of the subsequent burning of the body.

It is proper to notice in this place the frequent occurrence within a recent period of what are called "*Garrote robberies*." The system of murder normally pursued by the Thugs in India appears to have been imported into England, and many lives have been destroyed in the manufacturing districts and in large towns, by the employment of strangulation for the purposes of robbery. In spite of numerous convictions, there is reason to believe that many criminals still set the law at defiance. The rigorous proof required of facts which under these assaults can rarely admit of proof, confers complete impunity on the assailants. The attack is made during darkness; the person is seized by the windpipe from behind, or a bandage is thrown around his neck; and this is suddenly tightened while accomplices are engaged in perpetrating robbery. The nature of the assault by pressure on the windpipe renders it impossible to give an alarm or call for assistance. The person assaulted, if he should recover, is seldom able to identify an assailant; he is attacked from behind, is rendered immediately senseless and powerless, and can rarely offer resistance. Recovery or death in such cases depends on the lapse of a few seconds, more or less, during which the constriction of the neck is continued—on the degree of constriction, and on the age, sex, and strength of the constitution of the person assaulted. An attempt at strangulation, as in garroting, besides inflicting serious local injury to

the windpipe and other parts near to it, may cause a state of insensibility which may continue for some hours. There is severe pain in the throat, with difficulty of speaking and swallowing, and if the larynx be seriously injured there may be loss of voice. Dumbness, however, is not one of the secondary symptoms; and loss of voice is usually only temporary during the pressure. By the 24th and 25th Victoria, c. 100, s. 14, it is enacted, *inter alia*, that "whosoever shall attempt to drown, suffocate, or strangle any person, with intent to commit *murder*, shall, whether any bodily injury be effected or not, be guilty of felony; and being convicted thereof, shall be liable, at the discretion of the court, to be kept in penal servitude for life, or for any term not less than three years, . . . or to be imprisoned for any term not exceeding two years." As the intent in these cases is to perpetrate *robbery*, and not *murder*, another section (21) has been framed, for the prevention of the crime of *garroting*: "Whosoever shall, by any means whatsoever, attempt to choke, suffocate, or strangle any other person, or shall, by any means calculated to choke, suffocate, or strangle, attempt to render any other person insensible, unconscious, or incapable of resistance, with intent, in any of such cases, to enable himself, or any other person, to commit, or with intent in any of such cases thereby to assist any other person in committing any indictable offence, shall be guilty of felony; and being convicted thereof, shall be liable, at the discretion of the court, to be kept in penal servitude for life, or for any term not less than three years, . . . or to be imprisoned for any term not exceeding two years," etc.

Marks of violence.—It may be inquired whether *marks* of violence on the body, or blood-stains on the clothes, furniture, or in the apartment, do not afford strong evidence of *homicidal* strangulation. The answer is—if the marks of violence are such that they could not possibly have arisen from any accident before death, or that they could not possibly have been self-inflicted, they afford the strongest evidence of murder. But the cases wherein so positive an answer can be returned are exceptions to the rule. It is not always in our power to distinguish *accidental* or *self-inflicted* from *homicidal* violence; and we are always bound to look to the probability of accident, or of previous attempts at suicide being the source of those personal injuries which may be apparent on a strangled body. There may be *several marks* on the neck, but then the person may have tried to strangle himself more than once. The throat may be cut—there may be a deep-seated stab or gunshot wound, involving some of the important organs of the body—or poison may be found in the stomach; but in a purely medical point of view, how are we to know that the deceased did not actually make the marks, inflict the wounds, or take the poison before he succeeded in strangling himself? In the chapters on Drowning and Hanging, we have seen what suicides can do when they are desperately bent on destroying themselves. Wounds and personal injuries often create serious difficulties to a medical jurist, which it requires the greatest caution and prudence on his part to meet and explain. The prejudice of the public mind is such, that the discovery of a strangled person, with any marks of personal injury or of poisoning in his stomach, would, in most cases, lead to a charge of murder, unless the facts rendered it clearly impossible that any attempt could have been made on

his life. It is against this prejudice that a medical witness must strenuously guard himself: he may be abused for not joining in the outcry of the vulgar, but the best recompense for this abuse, will be the conviction that he is interposing the shield of science to protect a possibly innocent fellow-creature from the senseless denunciations of ignorance. Further, before a charge of murder by strangulation is raised against any person from marks or appearances found on a dead body, care should be taken that they admit of no other reasonable explanation than the direct application of violence. Even if marks indicative of strangulation are discovered, the question arises whether they may not have been produced by the deceased upon himself in an attempt at suicide which may have failed. If the body of a person is allowed to cool, with a handkerchief, band, or tightly fitting collar round the neck, a mark resembling that of strangulation will be produced. Before any opinion is given that murder has been perpetrated or attempted, the medical proofs on which reliance is placed should be clear, distinct, conclusive, and satisfactory.

In the dead bodies of infants and children, in whom the neck is short, a mark is occasionally seen which arises from the bending of the head; and in short-necked persons a similar mark or depression has been noticed after death, in front of the neck. These marks are then rendered more prominent by their assuming a livid appearance. They might, at first, be mistaken for marks produced by a ligature in an attempted strangulation. In one case a death from apoplexy was attributed to homicidal strangulation from a cadaveric change of this kind. ("Ann. d'Hyg.," 1859, vol. 1, p. 139, and vol. 26, p. 149.) The matter was set right by the late M. Ollivier. Homicidal strangulation may be perpetrated on the weak and infirm without causing any noise or creating alarm. In the first place, if the throat is at once seized and firmly compressed, no cry can be made, nor any noise produced to excite the attention of those who are near. In June, 1857, an aged woman was strangled in her shop by an apprentice in so short a time and so quietly, that her husband, who was only separated from her by a slight partition, heard no noise or disturbance during this act of murder. ("Ann. d'Hyg.," 1859, vol. 1, p. 157.)

It cannot be disputed that in contested questions of suicidal or homicidal strangulation, rare as they are, we must be often greatly indebted to evidence founded on circumstances, as well as to moral presumptions. How far a medical jurist may be allowed to make use of these in the formation of an opinion, it will be for the court to determine. Generally speaking, his duty is rigorously confined to the furnishing of medical evidence from medical data alone; but instances present themselves in which this rule must be departed from, or the course of justice will be impeded. Besides, there are numerous circumstances of a collateral nature which may materially modify a medical opinion. Thus the sight of a ligature, the state of the dress, and the attitude of the deceased when discovered, although not strictly medical circumstances, bear directly upon medical opinions; and that evidence ought not to be objected to which is partly founded upon facts of this nature. It must occur to all, that without circumstantial evidence, the best medical opinion in these cases will often amount to nothing. It may be, for example, no more than this: the case

is either one of homicide or suicide; and why is such an indefinite answer to be returned? Because in the abstract view of strangulation, it is not easy to determine whether a ligature was *suicidally* applied round the neck or not. The appearances may be in many cases the same, and where they are different, this difference may be due to accident, so that it is a mistake to suppose that we must look to medical circumstances *alone* for clearing up this intricate question. On some occasions the theory of homicide or suicide will be equally consistent with the facts. The cases of *Dr. Frank* and his son, which occurred at Brighton in November, 1855, were of this ambiguous character. Whether the son strangled himself, or was strangled by his father, was a question which could not be satisfactorily solved by medical, moral, or circumstantial evidence. Unfortunately, the bodies did not undergo a proper medico-legal inspection.

In all fatal cases resulting from acts of suicide, the means by which strangulation was produced, will be found upon the neck. The condition of the mark on the neck, the course and direction of the cord, the mode in which it was secured or fixed, in order to produce effective pressure on the windpipe, the amount of injury to the muscles and parts beneath, are circumstances from which, if observed at the time, a correct medical opinion may generally be formed. If the means of constriction are removed, or the cord or ligature is loosely applied, these facts, unless explained, are presumptive of homicidal interference.

There is another condition in which a presumption of homicide will be justifiable. A man, in strangling himself, is not likely to vary the means. The act is commonly due to a sudden impulse, if we may judge from the moral proofs afforded in the instances on record. The article which is nearest to the suicide is seized, and made the instrument of self-destruction. It has already been stated as doubtful whether a person could strangle himself by the mere application of the fingers to the windpipe: the discovery of such *marks only* as would indicate this kind of strangulation, therefore, renders suicide in the highest degree improbable. But these marks may be sometimes ascribed to the deceased having fallen with his hand possibly applied to his neck, and the inference will be drawn that they have accidentally resulted from the pressure of his own fingers. This is an improbable mode of accounting for the production of ecchymosis or excoriation of the skin in front of the neck. If, besides these marks of fingers, we find a circular mark, with a ligature still around the neck, the presumption of murder becomes very strong. It may be said that a person might at first try to strangle himself with his fingers, and not succeeding, might afterwards employ a cord. But the degree in which the coincidental impressions exist, will assuredly in general remove this objection.

Imputed strangulation.—Hitherto the subject of strangulation has been considered in reference to the dead. But a living person may charge another with attempting murder under such circumstances, and here a medical jurist will have the not very arduous duty of detecting and exposing the imposture. It has been considered so improbable that any one would seriously attempt to strangle himself, and then impute the act to another, that medical jurists have given but little attention to this subject. A case tried in France in March, 1864 (*Affaire Armand et Mau-*

rice Roux), has shown the great importance of it, and how easily medical men and the public may be deceived by a plausible story (*infra*). As in reference to imputed wounds, so in these cases impostors rarely produce such injury to themselves, as to place their lives in jeopardy. The cord is loose round the neck, or there would be speedy death; it is not so secured as to press with great force on the air-passages, to cause the tongue to protrude, or to produce lividity of the face and neck, or ecchymosis in the conjunctivæ and the skin. It is either a ligature or a rope which is used by the impostor: he does not commonly resort to manual violence to his throat. The marked feature of a really homicidal attempt is in the great amount of violence done to the neck; and the account given by the impostor will be inconsistent in its details, and not reconcilable with the ordinary effects of homicidal strangulation. Tardieu met with a case, in which a young woman of good social position, wishing to excite some public sympathy, alleged that she had been made the victim of a political conspiracy. One evening she was found at the door of her room apparently in a very alarming state: she could not speak, but indicated, partly by gestures and partly by writing, that as she was entering her room a man had attempted to strangle her by pressing his hand upon her neck, and at the same time had stabbed her in the chest with a dagger. On close examination it was found that there were two stabs which had penetrated only through the outer clothing. But the most singular effect of the alleged attempt at strangulation was that, instead of producing a difficulty of speaking and alteration of the voice, it had been followed by complete dumbness! M. Tardieu, who was officially authorized to examine the case, could find on the neck no trace of any attempt at strangulation; and on assuring the young lady that the loss of voice under such circumstances could not last for more than a minute, she at once admitted that there was no foundation for the charge! (“Ann. d’Hyg.,” 1859, vol. 1, p. 163.) On this occasion no person was accused: but the case is different when, for the purpose of extortion or other base motives, one or more persons are charged with an attempt at murder. A flagrant instance of this kind occurred in France, in which a wealthy merchant of Montpellier was charged by his servant, *Maurice Roux*, with having attempted to murder him by strangulation. The case was tried in March 1864, before the Court of Assizes of the Bouches du Rhone; and, fortunately for the interests of justice as well as for the credit of medico-legal science in France, it ended in a complete acquittal of the accused. (*Affaire Armand et Maurice Roux*, Paris, 1864. “Relation Medico, légale de l’Affaire Armand,” &c., par A. Tardieu. “Annales d’Hygiène et de Médecine Légale,” 1864, vol. 1, p. 415.)

It may be observed in reference to these imputed cases, that men who deliberately strangle others, either draw a cord tightly, or secure it by a knot. The pressure to the neck is not so gentle as to leave no mark whatever, or to allow the strangled person to breathe and watch all that goes on around him! Slight marks of violence about the neck should be therefore viewed on these occasions with great suspicion. As a rule, a man does not half-strangle any more than he half-stabs or half-poisons another; but the impostor stops short of this stage, as he has no intention to destroy himself. If, as is most improbable in attempted homicide,

arise from large masses of food blocking up the larynx. If the glottis (the opening of the windpipe) be completely closed by food, death may take place suddenly; although the person so situated may be capable of making some exertion or of moving from the spot. Dr. Mackenzie relates a case in which a man was suddenly choked by swallowing a large piece of meat: he immediately walked across the street to a chemist's shop, and soon after entering it, he fell down in a state of insensibility. After death the throat was found to be filled with a piece of beef, which rested on the glottis, and had pressed the epiglottis forward. Part of the mass had entered the windpipe through the rima glottidis, and had thus caused death by suffocation. It is probable that, in this and similar cases, the foreign body does not so completely close the aperture as to prevent some degree of respiration, but the blood being imperfectly aerated, asphyxia is speedily induced. ("Ed. Month. Jour.," July, 1851, p. 68.) A man, æt. 31, was put to bed drunk, having previously vomited; and shortly afterwards he was found dead. On inspection, Dr. Jackson, of Leith, discovered the usual appearances of asphyxia, *i. e.*, congestion of the lungs and of the right cavities of the heart. He was thus led to examine the air passages carefully, and he found lying over the upper opening of the windpipe (rima glottidis) a thin and transparent piece of *potato-skin* so closely applied to the fissure as to prevent breathing. The man had died accidentally suffocated from this mechanical cause. He had had potatoes for dinner the day before; the piece of skin had probably been thrown up at the time of vomiting, and had been drawn back by inspiration into the singular position in which it was found. Owing to intoxication, the deceased was unable to cough it up. I agree with Dr. Jackson in thinking that this case conveys a caution in making inspections. In England the verdict would most probably have been, "Died by the visitation of God," without an examination of the body! The result clearly shows that in every case of sudden death there should be a strict investigation. ("Ed. Med. and Surg. Journ.," April, 1844, p. 390.) Dr. Wright, of Birmingham, describes the case of an old woman who, during a violent fit of coughing, suddenly fell back in her bed, struggled convulsively, and died in a few seconds. After death, a pellet of tough mucus was found in the rima glottidis, so that the deceased was literally suffocated with her own phlegm. ("Patholog. Researches," 1850, p. 7.) In November, 1877, a man was suffocated while at dinner by swallowing his artificial teeth. In another case, a man died from suffocation by swallowing an oyster. In the case of a child, æt. 8 (Aug. 1878), it was proved that suffocation had been caused by a gooseberry, which had been swallowed, blocking up the glottis. In the "Med. Gaz.," vol. 29, p. 146, there is a case reported in which a child was suffocated by a pea, and on another occasion, January, 1879, an orange-pip was the fatal cause of obstruction.

A person may die suffocated, not from the act of swallowing food, but by reason of part of the contents of the stomach finding their way into the air passages. Whenever vomiting is followed by an inspiration while the vomited matters are in the mouth, the food is very liable to be drawn by aspiration into the trachea, bronchi, and pulmonary cells, and to cause suffocation. Pressure on the body may have the same effect

as the act of vomiting. A man was struck several blows with the fist, he was then stabbed in the nape of the neck, and finally his body was trampled on by his assailants. He died before any assistance could be rendered. On inspection the air passages were found to contain a large quantity of pulpy matter such as existed in the stomach. The wounds received were only flesh wounds, no large bloodvessel having been injured. Nevertheless one expert attributed death to loss of blood from the wounds—another assigned it to asphyxia from the food vomited by the deceased passing into the lungs during an inspiration. MM. Engel and Hauska were able to prove that asphyxia was the cause of death, and that the assailants were responsible. The food had been forced into the fauces by the act of trampling on the body. ("Ann. d'Hyg.," 1868, 1, 450; and 2,226; and 1869, 1, 471.) This mode of death by suffocation, as a result of violence to the abdomen, is probably more frequent than it is commonly supposed to be. It is likely to occur in the maltreatment of drunken persons. Dr. Behrend has reported a case in which suffocation was caused by the aspiration of food, with a full account of the post-mortem appearances, in Horn's "Vierteljahrsschrift," 1868, 1, 123. Accidental suffocation from food is one of those causes of violent death which is recorded in the Registrar-General's returns. It appears from the report of mortality in England and Wales that in one year there were 81 deaths from this cause.

A person has been wrongfully charged with causing the death of another, when the cause was really owing to the impaction of food in the larynx. A remarkable instance of this kind (which is reported in the "Lancet" for March 9, 1850, p. 313) occurred at Hillingdon. Deceased had had a quarrel with the accused, who was his son-in-law, and they were seen to fall to the ground together while struggling and fighting. They were separated. About two hours afterwards the deceased, who appeared quite well, was observed to rise from the dinner table and leave the room. He was found leaning against the cottage, as if in a falling position, and he expired in two or three minutes! The person with whom deceased had been fighting, was charged with manslaughter before a magistrate. At the inquest the medical witness stated that he found the organs of the body, excepting the brain, in a very healthy state. The brain was excessively congested, and he attributed death to apoplexy. The coroner desired the witness to examine the mouth and throat (which he had omitted to do at the inspection) as from the suddenness of death after eating, he (the coroner) thought the man might have been choked. This opinion turned out to be correct. A large piece of meat was found wedged in the opening of the throat; this had caused death by suffocation. It had not completely closed the air-passages in the first instance; hence the man was able to move from the dinner-table. The person accused of manslaughter was discharged. A medical jurist, however, must not lose sight of the fact that a foreign substance may be homicidally impacted in the larynx, and that, except by a careful examination of the body, death may be wrongly assigned to accident. A case reported by Dr. Littlejohn is in this respect instructive. In examining the body of a woman who it was stated had died suddenly, he found a quart-bottle cork inserted tightly into the upper part of

the larynx. The sealed end was uppermost, and was roughened by the passage of the screw. Fractures of the ribs were found, and it was quite clear that deceased had not died a natural death. It was suggested that the deceased, while extracting the cork from the bottle with her teeth, might, by the sudden impetus of the contained fluids, have drawn it into the position in which it was found. But this theory was negatived by the sealed end of the cork being uppermost in the throat, as well as by the structure of the parts. The medical opinion was that the cork must have been forcibly placed there by another person, while the woman was in a helpless state of intoxication. There was no reason to doubt that this was a deliberate act of murder. Five persons were present with the deceased at the time of her death, but it was impossible to fix with certainty upon the person who had committed the act, and the man on whom the strongest suspicion fell was acquitted on a verdict of "not proven." ("Ed. Med. Jour.," Dec. 1855, p. 511; and for a report of the trial, see p. 540.)

Cause of death.—In suffocation death takes place from apnoea or asphyxia; and this occurs with a rapidity proportioned to the degree of impediment existing to the passage of the air. There does not seem to be any reason to attribute death to apoplexy. The congestion of the cerebral vessels may be regarded as a consequence of the disturbance of the functions of the lungs. If the veins of the neck were opened, so as to prevent an accumulation of blood in the vessels of the brain, it is pretty certain that the prevention of respiration would destroy life under the same circumstances, and within the same period of time; therefore we may regard death from suffocation as resulting from pure asphyxia. In treating a case of suffocation, we have simply to allow of the renewal of air by removing, if this be possible, the mechanical obstacle to respiration. As a person does not die so soon from this as from other forms of asphyxia, life may be frequently saved by the following plan:—The mouth should be kept open by the left hand, protected with a handkerchief. The forefinger of the right hand should be then passed to the back of the throat, until the obstructing portion of food is reached, when a slight movement will cause its displacement. The results of experiments on dogs show that, even with a perfect closure of the windpipe, an animal may recover spontaneously after nearly *four minutes* deprivation of air; and there is every reason to believe that a human being might recover after the same length of time. If five minutes have elapsed there will be less hope of recovery. In drowning, the chances of recovery continue only for half the period observed in suffocation; the lungs are injured, and the water by which they are penetrated, forms a physical obstacle to the free admission of air. In hanging and strangulation there is sometimes great violence done to the parts about the neck. In suffocation these accidental obstacles to recovery do not exist: the surgeon has simply to readmit the air into the lungs. All experiments go to show that, even in this form of asphyxia, which is most favorable for recovery, the complete suspension of respiration for *five minutes* is fatal. Hanging and strangulation prove fatal from asphyxia within the same period of time, and drowning within a shorter period.

M. Vierordt has recently shown that spectral analysis will enable a

skilful observer to note the time at which life has passed into death, and whether there is a probability that life can be restored after a certain interval. If the fourth and fifth fingers are placed one over the other in a living body, and the line of union is brought before the slit of a spectroscope against the sunlight, or a powerful light, the two absorption-bands of oxy-hæmoglobin will be visible (pp. 247, 351). In the body of one really dead, whether from asphyxia by suffocation or any other cause, only one band of deoxidized hæmoglobin will be seen. M. Vie-rordt found that even in the living body, by a compression of the fingers, local death by the withdrawal of oxygen takes place rapidly, and the two bands pass into one. On removing the temporary pressure the oxygenated blood again circulates, and the two bands are restored. This may be regarded as a new method of testing the reality of death, whether from asphyxia or any other cause.

Post-mortem appearances.—There are rarely any considerable marks of violence externally. When the body has become perfectly cold, there may be patches of lividity diffused over the skin; but these are not always present. M. Tardieu has found upon the skin of the neck, face, and shoulders dotted or punctiform ecchymoses. (“Ann. d’Hyg.,” 1866, 2, p. 346.) The lips are livid; the skin of the face and neck may be pale, or present a dusky-violet tint, with small patches of ecchymosis. The eyes are congested: there is a mucous froth about the lips and mouth. The mouth, throat, and parts about the windpipe should be carefully examined for foreign substances. *Internally* the lungs and right cavities of the heart may be found distended with blood. The state of the lungs and heart is, however, subject to variation. The lungs are not necessarily found congested; and sometimes, as in a case referred to me in November, 1864, one lung may be found congested and the other not. M. Tardieu states, from his observations, that the *lungs* are of a reddish color, sometimes pale, not distended, and presenting occasionally only a slight degree of congestion at the base and posteriorly! A special character which he states he has invariably noticed in these organs consists in the presence of small ecchymosed spots or patches beneath the pleura or investing membrane. He describes these spots as of a dark color, and varying in size from a pin’s head to a lentil. In the adult they are of still larger size. Their number is variable; sometimes five or six may be found, at others twenty or thirty; and in other cases the surface of the lung may be so studded with them as to give to it a granite-like appearance. These spots of ecchymosis are sometimes agglomerated, at other times separated, but their outline is generally distinct and well defined on the surface of the lungs. They are most frequently seen at the root of the lungs, at their bases, and about their lower margin. They are owing to small effusions of blood from ruptured vessels, like true ecchymosis. They may be distinguished so long as the tissue of the lung remains unchanged. M. Tardieu states that he has seen these subpleural ecchymoses in the lungs of an infant which had been lying ten months in the soil of a privy! (“Ann. d’Hyg.,” 1855, vol. 2 p. 379.) He admits, however, that they may also be found in the lungs of children that have not breathed; hence no inference of death from suffocation should be drawn from this appearance in the lungs, unless

they have actually received air. In three instances he met with subpleural ecchymoses in lungs which sank in water, and had all the usual characters of these organs in a foetal state. The children had been born living, prematurely, and under conditions in which life by respiration could not be perfectly established: one of them had made several cries without effectually receiving air into the lungs (*loc. cit.*) (See Casper's "Klinische Novellen," 1868, p. 471.) This struggle to breathe may have produced the appearance resembling that of suffocation. In newborn children that die from suffocation, the thymus-gland has been found in a similar condition. The value of medical evidence derivable from the presence of subpleural ecchymoses in the lungs has been recently investigated by Dr. Legroux. I can here only refer the reader to his papers on the subject. ("Ann. d'Hyg.," July and September, 1878, pp. 174 and 335, and August, 1879, p. 164.) He believes, 1. That they may be seen in the lungs under various conditions, independently of the cause of death. 2. They are met with in different degrees in the different forms of death by asphyxia. 3. Unless accompanied by other indications of the mode of death, their presence will not enable us to determine the cause. In death from suffocation they are very numerous, from strangulation less numerous, and from hanging least numerous. 4. The presence of subpleural ecchymoses indicates a rapid and violent death, whether the violence be from internal or external causes.

A committee of the Société de Médecine Légale was lately appointed to examine the value of this post-mortem appearance as a positive indication of death by suffocation. They report (1) that subpleural ecchymoses may arise from spontaneous conditions irrespective of the cause of death; (2) that they may be met with in violent asphyxia by hanging, strangulation, submersion, by compression of the chest, and by suffocation, but in different degrees; (3) they are of value only when associated with other signs indicating the mode of death. ("Lancet," Aug. 31, 1878, p. 305.)

According to Tardieu, this dotted appearance of the surface of the lungs in suffocation is not attended with the apoplectic effusions in their substance which are met with in death from strangulation. Emphysema, or escape of air from rupture of the air-cells, is occasionally observed. The more rapidly suffocation has taken place, the more strongly marked are these ecchymosed spots. On the other hand, when the interruption of breathing has been slow and gradual, the substance of the lungs is more congested with blood, and then these dots or patches are merged in the general violet color of the surface of the organs. The lining membrane of the windpipe and larger air-tubes is sometimes pale, but commonly dark-colored when the lungs are congested. In the air-passages there is occasionally a frothy reddish-colored liquid in small vesicles.

M. Liman disputes the accuracy of the observations of M. Tardieu regarding this appearance described by him as characteristic of death from suffocation. ("Ann. d'Hyg.," 1867, 2, 388.) According to Dr. Ogston, the subpleural or punctiform ecchymoses observed by Tardieu were not present in the cases of nine adults who had died from suffocation. ("Brit. Med. Jour.," Sept. 1868.) On the other hand, they may be found in cases in which death has taken place from drowning, hang-

ing, and strangulation. Too much reliance must not, therefore, be placed on their presence or absence. These spots of ecchymosis were found by Dr. Ogston not only on the surface of the lungs, but on the heart, the scalp, the pericranium, the thymus gland, and other parts. (See "Ann. d'Hyg.," 1868, 1, 104.) That they are frequently absent in death from suffocation, as shown by the observations of other medical jurists. (See paper by Ssabinski, "Vierteljahrsschrift," 1867, 2, 146.) In an elaborate paper published by the same journal, Dr. Lukonsky, of Kiev, has endeavored to show, by a variety of experiments, the circumstances under which we may expect to find these ecchymoses in death from suffocation, and the cases in which they are likely to be absent. (Eulenberg, "Vierteljahrsschrift," 1871, 2, 58.)

Dr. David Page, who has experimented on this subject, agrees with the above named medical jurists in considering that M. Tardieu has been too hasty in making these dotted or subpleural ecchymoses a certain diagnostic sign of death from suffocation. According to him they probably arise from the continued and violent efforts to breathe in the early stage of apnoea. Their occurrence in the lungs of a hanged person would not therefore justify the inference that the person had been first suffocated and afterwards hanged. The same remark applies to drowning. Dr. Page found, on drowning animals, that subpleural ecchymoses were so numerous on the lungs as to give to the organs a granitic aspect. ("On the Value of certain Signs of Death from Suffocation," by Dr. Page, M.D., Edinburgh, 1873.) He has drawn the following conclusions from his experiments: 1. The ecchymoses or patches of extravasated blood found on the surfaces of certain internal organs, and notably of the lungs, are not peculiar to any one mode of death by apnoea, but are common to all. 2. The ecchymoses are not therefore diagnostic of death from suffocation. 3. They probably occur with greater frequency in suffocation, owing to the absence of interference with the cerebral circulation, and the opportunity which the means usually employed afford for respiratory struggles.

The *heart* presents no special appearance indicative of the mode of death, if we except the presence of small spots of ecchymosis found below the investing membrane, like those met with on the lungs. They have been found near the roots or origin of the great vessels, but are not so frequently observed in this organ as in the lungs. The blood is generally dark and fluid; sometimes coagula are met with. The stomach and intestines have been observed to present patches of lividity. Casper has found the kidneys more strongly congested with blood than the liver, spleen, and other organs. The vessels of the *brain* are sometimes congested, but at other times they do not appear to be more than ordinarily full. Their condition may be affected by the congested state of the lungs, as well as by the slowness or rapidity with which death takes place. Other appearances which have been described are of an accidental nature, and are not connected with death from suffocation.

In a case of alleged murder by suffocation, respecting which I was consulted in December, 1857, the following appearances were met with. The body was lying on the bed: the right leg was drawn up towards the body—the right arm was bent, with the hand directed towards the face;

the left hand was lying upon the chest. The lips are livid, the tongue protruded and swollen, and there was a bloody fluid issuing from the nostrils. There was no marks of constriction on the neck; the eyes were half open; the body was rigid and still warm. The face and neck were much swollen, and the skin of these parts, as well as of the chest, abdomen, arms, and legs, was covered with dark livid patches. The brain was gorged with venous blood. The lungs congested. The heart was soft and flaccid, and its cavities were empty. The mucous membrane as well as the tissues of the air-passages were much congested with dark liquid blood: the blood was everywhere liquid. The stomach contained a small quantity of dark-colored liquid, and the greater end was reddened. The spleen was congested. The emptiness of the cavities of the heart was at first considered to be inconsistent with death from asphyxia: but this condition of the heart is occasionally found. It may be stated that in this case the deceased, a female, was greatly exhausted by sickness and purging. On the second day of her illness she was found dead in the state described, and her husband was charged with having suffocated her.

Evidence of death from suffocation.—In medical jurisprudence there is not, perhaps, an instance in which we have fewer medical data upon which to base an opinion than in a case of alleged death from suffocation. The inspection of the body of a person suffocated, if we except the peculiar condition of the surface of the lungs described by M. Tardieu, presents so little that is peculiar, that a medical man, unless his suspicions have been roused by circumstantial evidence, or by the discovery of foreign substances in the air-passages, would probably pass it over as a case of death without any assignable cause—in other words, from *natural causes*. In examining the body of the woman *Campbell*, who was suffocated by *Burke* in Edinburgh, Dr. Christison was unable to come to a conclusion respecting the cause of death until some light had been thrown on the case by a collateral evidence. On this occasion a violent death was suspected, because there were marks of violence externally, and the face of the deceased presented some of the characters of strangulation. These conditions, however, are by no means essential to death from suffocation, and when they exist they can only be regarded as purely accidental accompaniments. Appearances similar to those found in the bodies of suffocated persons, if we except the dotted ecchymoses on the lungs, are frequently met with in inspections when death has taken place as a consequence of disease or accident. They can, therefore, furnish no conclusive evidence of the kind of death; they scarcely permit a witness to establish a presumption on the subject, until, by a careful examination of the body, he has ascertained that there is no other cause of death depending on organic disease or on violence. Medical evidence may, however, be serviceable in some instances. Thus, let the general evidence establish that a deceased person has probably been suffocated, the witness may have it in his power to state that the appearances in the body are consistent with this kind of death; that the body is in all respects healthy and sound, and that death was probably sudden—as where, for instance, undigested food is discovered in the stomach. The presence of ecchymoses on the surface of the lungs, may justify an opinion of

death by suffocation when no other cause is apparent. In all cases of this description, we must bear in mind that an opinion relative to the supposed cause of death, is to be formed from the *medical* circumstances and from what we have ourselves seen, unless it be otherwise allowed by the court. From this want of clear evidence, a great difference of opinion on the cause of death frequently exists among medical witnesses.

Accidental suffocation is not unfrequent; and there are various conditions under which a person may die suffocated only discoverable after death. 1. Diseases about the tongue, larynx, or throat may have advanced to such an extent as effectually to prevent breathing. 2. The deceased may have fallen, and the mouth become covered with dust, ashes, mud, or other substances; and if helpless, as in the case of an infant or an aged person, or of one who is intoxicated, death may thus easily take place. A child was found dead in a room, with its face in the ashes under a grate: it had fallen during the absence of the mother, and, from its helpless condition, had speedily become suffocated. Some of the ashes were found in the windpipe. ("Med. Gaz.," vol. 17, p. 642.) In March, 1878, a boy died from suffocation under the following circumstances. He was playing in a corn-loft with some companions, when, in order to hide himself, he got into a wheat-bin about eight feet deep. He was drawn through the wheat towards the machine, and was thus buried in the corn. Although extricated in a few minutes, he was quite dead.

In trials for murder or manslaughter, a medical opinion respecting the accidental suffocation of a drunken person under similar circumstances, is occasionally required. These persons, it must be remembered, are generally as helpless as children: if they fall in a position so that the mouth is covered, they may be so powerless from intoxication as not to be able to escape. A case was brought into Guy's Hospital in 1870, in which a man subject to epileptic fits had lost his life by accidental suffocation. He was found dead, lying with his face in a quantity of mud. On a post-mortem examination the teeth and nostrils had liquid mud adhering to them, and the tongue was thickly coated with it. The right side of the heart was full of blood, and there was a large quantity on the left side extending into the aorta. The blood, as is frequently the case in sudden death, was liquid. There were a few gritty particles in the trachea, but no froth. There was no doubt that the man had died from asphyxia, as a result of accidental suffocation during a fit. ("Lancet," 1870, vol. 2, p. 82.) In November, 1877, an inquest was held in London in which it was proved that the deceased was found dead in bed, lying with his face downwards and one arm under his head. The medical evidence showed that the cause of death was suffocation, by reason of the deceased having turned with his face to the pillow, and so covered his mouth and nostrils. At an inquest, held in February, 1880, the evidence showed that a young lady was found dead in her bed, and the bedroom door locked. A medical man who was called in stated that the body was completely covered with heavy clothing. It was in a fixed position and the legs were drawn lightly up. The last effort had been an act of violent vomiting. The body was slightly warm. He attributed death to suffocation. The weight of clothes worn, or bed-clothes, may be

so great as to prevent a free action of the chest, and cause suffocation. 3. A portion of food may have remained fixed in the larynx or throat. Children are sometimes accidentally suffocated by drinking boiling water from a tea-kettle. The parts about the larynx then become swollen from the action of the hot water, and breathing cannot take place. 4. Accidental suffocation is not uncommon among infants, when they sleep with adult persons. A child may be in this way speedily destroyed. Even the close wrapping of a child's head in a shawl to protect it from cold may effectually kill it, without any convulsive struggles to indicate the danger to which it is exposed (p. 484, *post*). Convulsions by no means necessarily attend on death from suffocation.

Those instances of accidental suffocation which depend on disease, or on the impaction of food, are easily known by a careful examination of the parts about the throat; generally speaking, they present no difficulty. In other instances,—when a child or a drunken person is presumed to have been suffocated owing to the position in which he has fallen, evidence as to the position of the body, or even the actual sight of the body, is necessary before forming an opinion. The following question may here arise: Was the position such as to be explicable on the supposition of accident? Was it not such a position as might have been given to it by a murderer? Could not the deceased have had strength or presence of mind to escape? Could he have been actually suffocated in the position in which his body was discovered? A little reflection upon the circumstances—for here something more than *medical* facts will be required—may enable us to give satisfactory answers to these questions.

Some singular cases are on record, in which persons have wilfully destroyed themselves by blocking up the throat mechanically. An instance of this form of *suicide* is reported in the "Edin. Med. and Surg. Journ.," April, 1842. A woman confined in prison forced a hard cotton-plug into the back of her throat. The cavities of the chest and abdomen had been already examined, and a medical certificate given that the deceased had died of apoplexy! The body was sent to one of the anatomical schools, and on re-inspection it was accidentally found that the throat was firmly blocked up with a plug of spindle-cotton.

Homicide by suffocation is not very common, although it is a ready means of perpetrating murder. Hitherto the cases which have come before our courts have been those either of infants, of the aged and infirm, or of persons enfeebled by illness. In regard to the latter, the rigorous administration of the law has succeeded in putting a check to this crime; but with respect to children, it probably yet continues. Death by suffocation is most difficult to detect; and, unless the assailant has employed an unnecessary degree of violence, it is probable that the crime may pass altogether unsuspected. Homicide by suffocation would not be attempted on healthy adult persons, unless they were in a state of intoxication, and thereby rendered defenceless. It is certain that most individuals would have it in their power, unless greatly incapacitated by disease or intoxication, to offer such a degree of resistance as would leave upon their bodies indubitable evidence of murderous violence. Death by suffocation may be considered as presumptive of

homicide, unless the facts are clearly referable to accident. Accidental suffocation is, however, so palpable, from the position of the body and other circumstances, that when death is clearly traced to this cause, it is not easy to conceive a case in which it would be difficult to distinguish it from one of actual murder. In some instances, the very means that have been adopted to produce suffocation may forbid the supposition of accident, and clearly establish the fact of homicide.

The suffocation of new-born children, by the introduction of substances into the mouth, is not unfrequent. The unnecessary force employed generally leaves traces of violence, which may be easily discovered by a careful examination, even should it happen that the substance used for the murderous purpose has been removed. Dr. Parrot met with the following case. A child at one year, after it had been fed with a bottle, was put to bed at six o'clock and died at midnight with all the signs of dyspnoea. On inspection ten hours after death, the lower lobes of the lungs were found softened, of a grayish color, and apparently pulpy. Curdled milk was found in the trachea and bronchi. There was no doubt that the milk had been vomited after the child was put to bed, and on account of the horizontal position, a portion of it had been drawn by aspiration into the air-passages and had caused suffocation. ("Lancet," 1873, 1, p. 669.)

It is necessary to point out a dangerous practice common among ignorant nurses, which, without exciting suspicion on the part of a coroner or medical witness, may be an occasional cause of death in infants. In order to quiet a child, and to enable a nurse to sleep without disturbance, a bag made of wash-leather or rag containing sugar, is thrust into the child's mouth. It is thus completely gagged, and the child soon becomes quiet, respiring chiefly through the nostrils. If these by any accident become obstructed, or by the act of aspiration the bag should fall on the back of the throat, death by suffocation must inevitably result, the infant being perfectly helpless! The suspension of breathing may be so gradual that the child may die without crying or convulsions. The removal of the bag from the mouth, as no violence had been used, will remove every trace of the cause of death; and, in order to exculpate herself, the guilty person may ascribe death to "fits." In one instance, within my knowledge, an infant was timely saved by the mother having discovered, while the nurse was sleeping, a mass of wash-leather projecting from its mouth. The woman awoke, and attempted to remove and conceal the leather, but she was detected in the act. The detection of this dangerous practice can only be a matter of pure accident; hence a fatal case can be rarely the subject of a coroner's inquest, and even then medical evidence may fail to throw any light upon the cause of death. In one instance only have I known it to give rise to a criminal charge (*Reg. v. Cox*, Warwick Lent Assizes, 1848). The mother, a pauper female, was tried for the attempt to suffocate her infant, eleven days old. The child was discovered by another person with a piece of rag hanging from its mouth. It was livid in the face, but when the rag was removed it made a violent gasp, and recovered its breath. There was no malice on the part of the prisoner, but it was made a strong point in her favor that instances had

occurred in the workhouse, in which women had with impunity put rags with sugar into the mouths of infants in order to soothe and keep them quiet! The jury acquitted her. This admitted practice of infantile suffocation in the Warwick workhouse, appears to have passed without reprimand or even comment, although this plan of soothing infants is just as likely to be fatal to them as that of encircling their necks with tight ligatures.

SMOTHERING.

Smothering is a variety of suffocation, and consists in the mere covering of the mouth and nostrils in any way so as to prevent the free ingress and egress of air. Like drowning, hanging, or strangulation, it produces death by asphyxia. In new-born infants it is not an unusual occurrence, sometimes originating in accident, and at others in criminal design. An infant may be speedily destroyed by smothering. If the mouth be only lightly covered with clothing, or slightly compressed, so that respiration is interrupted, as in the act of carrying a child in the arms, this will suffice to cause death; and, as it has been already remarked, death may take place without being preceded by convulsions or other striking symptoms. Smothering is not often resorted to as a means of perpetrating murder, except in infants, or in debilitated and infirm adults. In a case which occurred at Ayr, a woman was charged with the murder of her child by smothering it in her shawl. She was travelling in a steamboat: it was a cold stormy day, and she had wrapped the shawl closely round the head of the child. There could be no doubt from the moral circumstances, that she had intended to kill it; but the defence was that she had merely intended to protect the child from the cold, and it was suffocated before she was aware of it. There were no facts to exclude this defence, and the woman was acquitted. But children may be thus accidentally destroyed through the ignorance of persons who nurse them.

A false accusation may be made under these circumstances, and a man wrongly charged with murder or manslaughter. For an illustration of this kind the reader is referred to the "*Brit. Med. Jour.*," Nov. 1879, p. 707.

According to the late Mr. Wakley, infants are frequently found dead, owing to their being suckled at night, while the woman is in bed. The child's face is pressed on the breast: mother and child fall fast asleep; the head slips beneath the clothes, and the child is then quietly suffocated. There is no mark of pressure or violence on the body. ("*Lancet*," Jan. 16, 1858, p. 69.) This statement is strongly confirmed by the annual returns of the Registrar-General. In his report of deaths in England and Wales for the year 1871 it is stated that in that year 480 children died from suffocation by bed-clothes, and 277 by overlying. A case, apparently of this kind, was communicated to me by Mr. Nason, in Sept. 1860. The child (five days old) died quietly on its mother's arm while lying in bed. There was much lividity about the head, neck, and back; but there were no marks of violence. The bronchial tubes of the right lung contained bright florid blood. The left lung was gorged with

blood, but none had escaped. The heart was firmly contracted, and there was only a small quantity of blood in its right cavities.

According to the returns of the Registrar-General, suffocation in bed from "overlaying" is the most frequent cause of violent death among infants. In ten years (1858-67) the total deaths registered in London from this cause were 3612, or 361 per annum; and 2070 in the five years (1863-7), or on an average of 414 per annum. Infants are readily smothered by the bed-clothes accidentally covering the mouth and nostrils, and they have not the power to change their position. The late Dr. Lankester, within a short period of his death, held 200 inquests on the bodies of children thus found suffocated in bed. In a return of inquests held in Liverpool in 1864, it appeared that out of 960 inquests there were 143 on infants and children who had been suffocated, chiefly between the Saturday and Monday of each week.

The *appearances* met with in the bodies of three children who had died under these circumstances, are thus described by Mr. Canton (Nov. 1848): *Externally*: Features placid; lips congested; eyes not unduly prominent; conjunctivæ rather reddened; hands clenched; no patches of ecchymosis found on the skin. *Internally*: Head—patches of effused blood here and there beneath the pericranium; great congestion of the pia mater, accompanied by numerous effusions of blood, varying in size from a pin's point to a silver penny in superficial extent; a little clear fluid in the ventricles; some frothy mucus in the windpipe and bronchi, with redness of their lining-membrane. The lungs were much congested and crepitant, whilst beneath the pleuræ, blood was effused, presenting numerous small bright-red patches and fine points (punctiform ecchymoses). The pericardium contained some serum, and was spotted in its whole extent in the manner described; the vasa vasorum of the heart's great vessels and thoracic aorta were minutely injected. The right cavities of the heart in all the cases contained dark liquid blood; the left cavities were nearly empty; the tissue of the organ was free from effused blood. The surface only of the thymus-gland was mottled like the heart.

There is a prevalent notion that congestion of the lungs is an invariable accompaniment of death from suffocation, and where this was not found, it has been hastily assumed that death has taken place from some other cause. Some remarks on this post-mortem appearance have been made in the chapter on Drowning; and it is desirable, in reference to future cases, to point out the fallacy involved in the assumption that congestion of the lungs is necessarily present in death from suffocation. Mr. Watson observes that the gorged state of the right side of the heart and lungs is greatest where the act of suffocation (asphyxia) has been slow and gradual, by the access of air to the lungs not having been completely prevented. When, on the other hand, death has taken place quickly or suddenly from this cause, there is little or no unusual congestion of blood in the lungs or heart. ("On Homicide," p. 115.) At p. 118 he describes a case of death from suffocation in which the lungs were natural; and in the case of *Campbell*, for whose murder by suffocation *Burke* was convicted and executed in 1828-9, Dr. Christison and Mr. Newbigging found the organs within the chest perfectly natural, the lungs remarkably so, and

unusually free from infiltration. The blood in the heart and great vessels, as well as throughout the body, was fluid and black. ("Ed. Med. and Surg. Jour.," vol. 31, p. 239.) Again, in the case of *Carlo Ferrari*, for the murder of whom *Bishop* and *Williams* were convicted and executed in London, in 1831, the lungs were quite healthy, and *not congested*; the heart was rather small, contracted, and its four cavities were perfectly empty. (Taylor's "Elements of Medical Jurisprudence," 1836, p. 292.) The prisoners in this case confessed that they had destroyed the deceased by suffocation. From these facts it will be perceived that the actual state of the lungs and heart in the bodies of those who had been notoriously murdered by suffocation, is that which has been wrongly pronounced to be inconsistent with this mode of death.

Certain trials which took place many years since clearly proved that persons in a state of intoxication or infirmity had been murdered by smothering, for the sake of the money derived from the sale of the dead bodies! The victims were commonly destroyed by the assailant resting with his whole weight upon the chest, so as to prevent the motion of the ribs, and at the same time forcibly compressing the mouth and nostrils with his hands, to prevent the entrance of air. A case of this kind was referred to me for examination in 1831. (*Rex v. Elizabeth Ross*, Old Bailey Sessions, Dec. 1831.) It was remarkable for the fact that the prisoner was convicted of homicidal suffocation, although the body of the deceased was never discovered. ("Med. Gaz.," vol. 37, p. 481.) In *Reg. v. Norman*, C. C. C., July, 1871, the prisoner, a girl, æt. 15, was indicted for murder by suffocation. She was a nursery-maid, and had had the care of three children, the deceased, one of these children, being fifteen months old. There were three other charges of murder by suffocation against her, and one of an attempt to murder. There were suspicious marks of violence on the lower lip of deceased, as if produced by pressure of the mouth against some hard substance. The medical witnesses attributed death to suffocation by pressure on the mouth, but admitted that the marks might have been accidental. On this admission the prisoner was acquitted. On the trial for the attempt to murder, the girl was convicted, and the evidence given in this case threw a light upon the mode in which she might have perpetrated the four murders with which she was charged. A little boy, æt. 10, was heard to give an alarm while in bed; it was like a stifled cry. The prisoner was caught in the act of getting off the bed. The boy was in great agitation, and said that the prisoner had tried to strangle him while he was sleeping. He was awoke by feeling a hand on his mouth and throat. He tried to make a noise, upon which the prisoner, who was lying upon him, gave him a sweet, and told him not to cry. His lips and throat were very sore. The prisoner was convicted and sentenced to ten years' penal servitude. There can be no doubt that the four murders were all perpetrated in a similar manner, by burking—the children being helpless, and unable to give an alarm. The conviction of the prisoner on the attempt, simply arose from this child being older and better able to resist. The facts show that medical science in many of these cases is powerless to aid the law. It is not always possible to distinguish murder by smothering, or suffocation from accident.

In reference to the case of *Campbell*, Sir R. Christison observes "that the conviction in the public mind, that a well-informed medical man should always be able to detect death by suffocation simply by an inspection of the body and without a knowledge of collateral circumstances, is erroneous, and may have the pernicious tendency of throwing inspectors off their guard, by leading them to expect strongly marked appearances in every case of death from suffocation. That such appearances are very far from being always present ought to be distinctly understood by every medical man who is required to inspect a body and give an opinion of the cause of death." (Op. cit., p. 243.) At the same time, in the absence of marked appearances to indicate violent death, due caution should be used by a medical witness in expressing an opinion. At the trial of the prisoner *Burke*, Dr. Christison restricted his opinion by stating that death by violence was, from the medical circumstances alone, *very probable*—a degree of caution which on similar occasions it will be desirable for a medical witness to imitate. Under the rule of English jurisprudence, by which accused persons are not allowed to be interrogated, it is not possible to carry medical evidence further than this. Although there is nothing in the act of suffocation by burking by which the hand of a criminal can be clearly and unequivocally traced, yet the excessive violence used sometimes leaves behind it appearances irreconcilable with accident. The pressure caused by a person sitting on the chest may suffice to produce fracture of one or more ribs. In the Spalding case, elsewhere referred to, in addition to the appearances in the lungs, and and the congestion of all the soft organs with dark-colored blood, the fourth and fifth ribs on the right side were found fractured, one being completely and the other only partially broken through. Dr. H. P. Stiles ascribed these fractures to violent compression of the chest, the person sitting suddenly on the chest of deceased with great force. (*Reg. v. Howitt Veisey and Ireland*, Lincoln Winter Assizes, 1880.) The medical evidence clearly showed that this was a case of homicidal suffocation.

As an accident, smothering may be conceived to take place when a person falls, in a state of intoxication and debility, so that his mouth is in any way covered, or the access of air to the mouth or nostrils is interrupted. On an inspection of the body the appearances elsewhere described will be met with in the lungs and heart. If the person has been able to struggle, it is probable that slight marks of violence in the shape of scratches or bruises may be found about the mouth and nostrils, with bruises or marks of pressure on the chest, legs, or arms, and redness of the mucous membrane, with a bloody mucous froth as well as foreign substances in the air-passages. The marks of violence may be slight, or even entirely absent. In a case of suspected murder a medical jurist should look for the special indications of suffocation in the lungs, the circumstances under which the body or bodies are found, the evidence of sudden death in the presence of food in the stomach, and lastly the absence of any other cause to account for death. All these sources of evidence may fail; and as the means by which homicidal smothering was accomplished are not likely to be found with the body, a medical opinion on the case may become little more than a conjecture. Still this may suffice when the evidence from extraneous circumstances is strong.

in which an animal could live without inconvenience for a period of three hours. When pure hydrogen was substituted for common air, the animal lived for nine minutes. This was taken to represent death from the privation of air or oxygen, and assuming this as a standard, the following table shows the time in which death occurred with different gases and vapors:—

	Mln.	Sec.
Pure hydrogen gas in	9	0
Common air saturated with ether	5	0
“ “ with chloroform	1	30
“ “ with bichloride of methylene	0	20
Pure nitrous oxide gas	0	25
Oxygen gas saturated with ether	8	30
“ “ with chloroform	0	25
“ “ with bichloride of methylene	1	45
Pure carbonic acid gas	0	8

These experiments were performed on rats. (See “Brit. Med. Jour.,” Oct. 4, 1873, p. 401.) In the experiments on dogs performed by the Committee of the Med.-Chir. Society it was found that under complete privation of air, the heart’s action continued for a period of eight minutes and twenty seconds. This very nearly corresponds to the time at which life ceases in pure hydrogen. These results show that the gases and vapors are directly poisonous agents, and that they do not produce their effects merely by excluding oxygen or air.

The cause of death mistaken.—The greater number of the poisonous gases are chiefly complex products of art, and are never likely to be met with in the atmosphere so abundantly as to produce injurious consequences; hence fatal accidents arising from their inhalation, most commonly occur under circumstances which can leave no doubt respecting the real cause of death. The peculiar effects of all of these it will not be necessary to describe in this place; but there are two, a knowledge of the properties and operation of which may, on certain occasions, be required of a medical jurist: these are the CARBONIC ACID and SULPHURETTED HYDROGEN GASES. Agents of this description can rarely be employed with any certainty as instruments of murder; and if they were so employed, the fact could be established only by circumstantial evidence. One alleged instance of murder by carbonic acid is, however, reported by M. Devergie. (“Ann. d’Hyg.,” 1837, vol. 1, p. 201.) Death, when arising from the breathing of any of the gases, is generally attributable to suicide or accident. In France it is by no means uncommon for a person to commit self-destruction by sleeping in a closed apartment, in which charcoal has been suffered to burn; while in England accidental deaths are sometimes heard of, where coal or coke has been employed as fuel in small and ill-ventilated rooms. On such occasions a person may be found dead without any cause apparent to the casual observer. The face may appear pale or livid, and the skin may be covered with patches of lividity. The discovery of a body under these circumstances will commonly be sufficient, in the eyes of the vulgar, to create a suspicion of murder; and some person with whom the deceased may have been at that period on bad terms, will perhaps be pointed out as the murderer. In such a case, it is obvious that the establishment of the

innocence of the accused will depend entirely on the discrimination and judgment of a medical practitioner. An instance, illustrative of the consequences of this popular prejudice, occurred in London, in 1823. Six persons were lodging in the same apartment, where they were all in the habit of sleeping. One morning an alarm was given by one of them, a woman, who stated that on rising she found her companions dead. Four were discovered to be really dead, but the fifth, a married man, whose wife was one of the victims, was recovering. He was known to have been on intimate terms with the woman who gave the alarm, and it was immediately supposed that these two had conspired to destroy the whole party, in order to get rid of the wife. The woman who was accused of the crime was imprisoned, and an account of the supposed barbarous murder was soon printed and circulated in the metropolis. Many articles of food about the house were analyzed in order to discover whether they contained poison, when all the circumstances were explained by the man stating that he had placed a pan of burning coals between the two beds before going to sleep, and that the doors and windows of the apartment were kept closed. ("Christison," p. 588.) A set of cases of a similar kind, in which there was at first a strong suspicion of poisoning, has been reported in the "*Med. Gaz.*," by Mr. Smith, of Liverpool (vol. 36, p. 987; see also "*Ann. d'Hyg.*," 1843, vol. 2, p. 56).

CARBONIC ACID.

This gas is freely liberated in respiration, combustion, and fermentation; it is also produced in the calcination of chalk or limestone, and is sometimes diffused through the shafts and galleries of coal mines, where it is commonly called "choke-damp." Carbonic acid gas is likewise met with in wells, cellars, and other excavations in the earth. In these cases it is generally found most abundantly on the soil, or at the lower part of the well; and it appears to proceed from the decomposition of animal and vegetable matters confined in such situations. The slow evaporation of water strongly charged with the gas, while trickling over the sides of these excavations, may likewise assist in contaminating the air. Damp sawdust, straw, or decayed leaves slowly absorb oxygen from a confined atmosphere, and set free carbonic acid.

Sir Humphry Davy believed that carbonic acid, in a perfectly pure state, did not pass into the trachea when an attempt was made to breathe it; the glottis seemed to close spasmodically at the moment that the gas came in contact with it. On diluting the carbonic acid with about twice its volume of air, he found that he could breathe it; but it soon produced symptoms of giddiness and somnolency. In a diluted state there is no doubt that it penetrates into the lungs, and that it is absorbed and circulated with the blood. In estimating the effects of this gas when mixed with air, a distinction must be made. The gas may either be simply added to the air, or it may be produced at the expense of the oxygen in the inclosed space or apartment. In the latter case, it must be remembered that every volume of carbonic acid thus produced, represents an equal volume of oxygen removed. Such an atmosphere is, therefore, more destructive than another in which the air and gas are in simple

admixture. If we assume that in each case the noxious atmosphere contains 10 per cent. of carbonic acid, then in one instance there will be 7 per cent. more of oxygen and 7 per cent. less of nitrogen than in the other, since the production of 10 parts of carbonic acid as a result of combustion implies the loss of 10 parts of oxygen. This difference in the proportions may not be, practically speaking, correct, because there is no apartment sufficiently closed to prevent air rushing in from the exterior while combustion is going on within it; but, nevertheless, the above statement may be taken as an approximation to the truth. The air in small apartments is rapidly vitiated by combustion, especially when the room is not properly ventilated by the door, window, or fire-place. In April, 1874, a man and his wife were found dead in their bedroom at Bristol, in the attitude of making their escape. A paraffine (rock oil) lamp was still burning on the table. The noxious vapor from this lamp, chiefly carbonic acid, in a small, ill-ventilated room, had sufficed to cause death.

The statements made by chemists and physiologists, respecting the proportion of carbonic acid in air required to produce noxious or fatal effects on human beings, are very conflicting. Small animals, such as birds and mice, have been generally made the subjects of experiment, but the results thus obtained, cannot be satisfactorily applied to show the relative action of carbonic acid on man. Berzelius stated that a proportion of 5 per cent. in air was not injurious, and that such a mixture might be usefully employed in the treatment of consumption. (*"Traité de Chimie,"* t. 2, p. 83.) Allen and Pepys inferred, from their experiments on guinea-pigs, that 10 per cent. of the gas would prove fatal to man. In the more recent experiments of Bernard this inference is corroborated by the fact that a bird died in two and a half hours in an atmosphere consisting (in 100 parts) of 9.5 of carbonic acid, 28 of oxygen, and 62.5 of nitrogen. (*"Les Substances Toxiques,"* 1857, p. 135.) In this case the proportion was less than 10 per cent., while the proportion of oxygen was 7 per cent. more than that existing in the atmosphere. On the other hand, Demarquay says that one part of carbonic acid (25 per cent.) and three parts of air produce in man but slight discomfort after being breathed for some time! According to this writer, most of the accidents caused by charcoal-vapor, confined air, and gases in fermenting vats, are wrongly ascribed to carbonic acid, and should be attributed to carbonic oxide, sulphuretted hydrogen, alcoholic vapors, or other gases not yet understood. (*"Chem. News,"* Aug. 4, 1865.) Those who have employed mixtures of carbonic acid and air for anæsthetic purposes have stated that air containing 20 per cent. of carbonic acid may be breathed without any injurious effects. Such a mixture would be composed (in 100 parts) of 20 of carbonic acid, 16 of oxygen, and 64 of nitrogen. In this mixture, if carefully made, oxy-combustion cannot be maintained; hence, if there was no error in the above proportions, it follows that a man can breathe with safety and live in air in which a candle will not burn! Bernard's carefully performed experiments are adverse to these statements. He found that animals died in atmospheres in which the proportion of carbonic acid varied from 12 to 18 per cent., while the amount of oxygen varied from 5 to 30 per cent. (*"Les Substances Tox-*

iques," p. 140.) When it is asserted that a person can thus breathe with impunity proportions which are fatal to life, it would be desirable to know how such mixtures were made, and whether proper care had been taken to prevent the breathing of air by the mouth and nostrils, while the supposed poisonous mixture was being inhaled. Such statements, founded on imperfect experiments, are highly mischievous, for they may lead to death in cases in which the mixture is accurately made, and administered to a person whose mouth and nostrils are closed against the ordinary atmosphere. If air can be breathed simultaneously, there is an end of the alleged poisonous proportion.

Symptoms.—The symptoms of poisoning by carbonic acid vary according to the proportion contained in the air which is breathed. In a concentrated state there is sudden insensibility, followed by death, unless the person is immediately removed into pure air. When the air is gradually poisoned so as to acquire its lowest poisonous proportion, insensibility comes on more slowly; and as in ordinary narcotic poisoning it is preceded by giddiness, somnolency, and loss of muscular power. When the gas is in a fatal proportion, the symptoms commonly observed are as follows: A sensation of great weight in the head, a sense of pressure in the temples, a singing in the ears, with a pungent sensation in the nose; a strong tendency to sleep, accompanied by giddiness, and so great a loss of muscular power that, if the person be at the time in an erect posture, he instantly falls to the ground as if struck. The breathing, which is observed to be at first difficult and stertorous (snoring), becomes suspended. The action of the heart, which on the first accession of the symptoms is very violent, soon ceases; sensibility is lost, and the person now falls into a profound coma, or state of apparent death. The warmth of the body still continues; the limbs are relaxed and flexible, but they have been observed in some instances to become rigid, or even occasionally convulsed. The countenance is livid or of a leaden color, especially about the eyelids and lips, but on some occasions it has been pale and placid. The access of these symptoms is stated to have been sometimes accompanied by a pleasing sensation of delirium, while at others the most acute pains have been suffered. In some instances there appears to have been irritability of the stomach, for the affected person has vomited the contents of his stomach in a semi-digested state. Those who have been resuscitated have felt pain in the head, or pain and soreness over the body for several days; while, in a few severe cases, paralysis of the muscles of the face has supervened on recovery.

The following singular case of death from carbonic acid was communicated to me by Mr. Procter, of York. The deceased, an old woman, occupied a room under one in which there was a quantity of nitric acid kept in store. Owing to some accident, a carboy was broken; the acid ran through the ceiling into the room below, acting upon and corroding the bed-coverings of the deceased's bed. As the room was quite filled with the nitric acid fumes, a chemist was consulted, and he advised that whiting should be freely used for the purpose of neutralizing the acid. This advice was followed, and several persons, who were in the room witnessing the operation, felt oppressed, and were obliged to leave

it; they were observed to stagger as if intoxicated on reaching the street. The room was then completely closed, and the whiting allowed to remain in contact with the acid. The deceased had suffered from diarrhoea for a few days previously, and was obliged to resort to the night-chair, which was in the room in which the accident had occurred. As she remained absent half an hour, some persons entered the apartment, and found her in a chair unable to move. She was taken into another room, and on a medical man being called to her, he found her sleepy and comatose, and her mind confused; there was great difficulty of breathing—extreme lividity of the face and lips; the arms and legs were cold, and the pulse was full. In spite of efforts made to save her, she died in about an hour from the time at which she had entered the room. Those who found her in the apartment do not appear to have suffered. This was a case of slow poisoning by carbonic acid, for no carbonic oxide could have been evolved from the action of the acid on chalk. Age and debility from previous illness may account for the unusual circumstance that the deceased did not recover on being removed to a pure atmosphere.

Post-mortem appearances.—In some instances the face has been found livid and swollen, and the features distorted, but more generally it has been pale and placid, as if the person had died without a struggle in the position in which his body was found. The skin is sometimes livid, or presents patches of lividity, and the limbs are quite flaccid. The pupils have been found dilated. *Internally*, the venous system is filled with liquid blood of a dark color. In death from carbonic acid as a result of combustion, the blood has sometimes had a light-red color. The vessels of the lungs and brain are observed to be especially in a state of congestion. The tongue appears swollen, and sometimes the mucous membrane of the intestinal canal presents dark ecchymosed patches. The following appearances were met with thirty hours after death in the bodies of two adults, male and female, who died from the accidental introduction of carbonic acid into their bedroom from burning ashes. Externally there was nothing unnatural, excepting a few slight discolorations on the back of the man; internally there was congestion of the membranes and great vessels of the brain. Each lateral ventricle contained about half an ounce of clear serum; the lungs were gorged with dark blood; and the lining membrane of the air-tubes (bronchi) was slightly reddened. The left sides of the heart were nearly empty; the right contained a quantity of dark half-coagulated blood. The stomachs were healthy. The bodies were found on the floor of the bedroom in easy positions. The deceased persons had had the power to get out of bed, but were unable to escape from the chamber. It will be perceived, from this description, that there is nothing very characteristic in the appearances, and thus it is always easy to ascribe death to apoplexy or some other cause; but it should be remembered that carbonic acid itself is a narcotic poison, inducing cerebral congestion and apoplexy.

Analysis.—Sometimes a medical jurist may be required to state, for the purposes of justice, the nature of the gaseous mixture in which a person may have died. There will be no difficulty in determining whether

carbonic acid is or is not the deleterious agent in such a mixture. When it exists in a confined atmosphere its presence may be identified, if previously collected in a proper vessel, by the following characters:—

1. It extinguishes a taper if the proportion be above 12 or 15 per cent.
2. Lime-water, or a solution of subacetate of lead, is instantly precipitated white when poured into a jar of the gas; and the precipitate thus formed may be collected by filtration, and proved to possess the well-known properties of carbonate of lime or lead. Air containing only 1 per cent. of carbonic acid affects lime-water: if it amounts to 2 per cent. a few cubic inches will suffice to show its presence by the lime-water test. The *proportion* in which carbonic acid exists in a mixture may be determined by introducing into a measured quantity, in a graduated tube over mercury, a strong solution of potash. Absorption will take place after a certain time, and the degree of absorption will indicate the proportion of carbonic acid present. When this gas exists in a confined spot as in a well or cellar, it may be got rid of by placing within the stratum, a pan containing the hydrate of lime loosely mixed with water; by exciting combustion at the mouth of the pit; or, what is better when available, by a jet of high-pressure steam. Lives are often successively lost on these occasions, in consequence of one person descending after another, in the foolish expectation of at least being able to attach a rope to the body of his companion. The moment that the mouth comes within the level of the invisible stratum of gas, muscular power is lost, and the person commonly sinks lifeless. Carbonic acid may be collected for the purpose of testing, by lowering a bottle filled with fine sand, by means of a string attached to the neck, and guiding the bottle by another string attached to its base. When the bottle is within the stratum, it should be turned with its mouth downwards; and when the sand has fallen out, it may be rapidly raised, with its mouth upwards, by pulling the string attached to the neck. The bottle should be immediately corked and the contents examined.

Combustion in mixtures containing carbonic acid.—In reference to suffocation by carbonic acid, there is one circumstance which requires attention. It is a matter of popular belief—and, in fact, it is generally asserted by writers on asphyxia—that the burning of a candle in a suspected mixture of carbonic acid and air, is a satisfactory proof that it may be breathed with safety. The results of some experiments on this subject have led me to the conclusion that a candle will burn in air which is combined with even 10 or 12 per cent. of its volume of carbonic acid gas; and although such mixtures might not prove immediately fatal to man, yet they would soon give rise to giddiness, insensibility, and ultimately death, in those who, after having been once immersed in them, did not hasten to quit the spot. In air containing a smaller proportion than this (5 or 6 per cent.), a candle will readily burn, but it is probable that such a mixture could not be long respired without causing serious symptoms; hence the *burning of a candle can be no criterion of safety* against the effect of carbonic acid. It is true that it would not be safe to venture into a gaseous mixture in which a candle is extinguished; but the converse of this proposition is not true—namely, that a mixture in which a candle burns, may be always breathed with safety. It has been

observed on several occasions that the combustion of charcoal has been maintained in a room, in which persons have been found in a state of insensibility from breathing the vapors.

Diffusion of carbonic acid.—Of late years some important medico-legal questions have arisen, relative to the diffusion of this gas in air, when produced by combustion. It has been supposed that, owing to its great density (1.52), it would collect on the floor of an apartment, would gradually rise upwards and suffocate persons at different times, according to the level on which they might happen to be placed. Questions on this subject have been variously answered, and a great difference of opinion has arisen among witnesses. There are two important points on which a correct answer to this inquiry must be based:—1st. The law of the diffusion of gases; and 2dly. The effect of heat in greatly diminishing the specific gravity of a gas naturally heavier than air. There is no doubt that in a narrow or confined vessel, exposed to air, carbonic acid is slow in escaping; nevertheless it mixes with air, and passes off rapidly in proportion to the surface exposed. In the course of an hour or two, in spite of its great specific gravity, none will be contained within the vessel. The well-known Grotta del Cane at Pozzuoli, near Naples, has been referred to by those who hold that carbonic acid always tends to remain on the lowest level; but it has been forgotten that, in this and similar excavations, carbonic acid is continually issuing from crevices in the soil, so that that which is lost by diffusion is continually replaced: hence the illustration proves nothing. It may suffice to state, that air and carbonic acid mix readily on contact in all proportions, although they enter into no chemical union. Thus then, at common temperatures, carbonic acid has no tendency to remain on the floor or soil, when there is a free access of air or contact with other gases. The heat of combustion diminishes the specific gravity of the gas, and the carbonic acid therefore ascends with the heated current of air, and diffuses itself in the upper part of an apartment, when there are no means of carrying it off. This is a fact demonstrable by many simple experiments.

CHARCOAL-VAPOR.

The vapor extricated during the combustion of charcoal is not pure carbonic acid, but a mixture of gases. It operates fatally when breathed, partly in consequence of the carbonic acid contained in it, and partly from the presence of a variable proportion of carbonic oxide. The proportions of these gases, however, are subject to variation, according to whether the combustion is vivid or not. When the charcoal was burning vividly, the quantity of carbonic acid was found by Orfila to be less than when it was either nearly extinguished or beginning to burn. In the former case the carbonic acid was in the proportion of about 11 per cent. by volume—in the latter the proportion amounted to about 14 per cent. Leblanc found that charcoal burning in the open air produced about $\frac{1}{2}$ per cent. of carbonic oxide. There is no doubt that a low or imperfect combustion is more favorable to the production of this gas, and it is considered to operate more powerfully on the human body than carbonic acid. According to Leblanc, a bird was killed instantly by breathing

air containing 4 or 5 per cent. of carbonic oxide; only 1 per cent. sufficed to cause death in two minutes. ("Ann. d'Hyg.," 1843, vol. 2, p. 54.) Charcoal-vapor may be regarded as a mixture of carbonic acid, carbonic oxide, aqueous vapor, and air partially deoxidized. There is also associated with it, at a low temperature, a small quantity of carburetted hydrogen. This does not appear to take any part in the fatal effects produced by the vapor; these are owing to the action of carbonic acid and carbonic oxide, and according to Bernard a mixture of the two is more destructive than either gas separately. ("Les Substances Toxiques," p. 212.) M. Leblanc endeavored to determine the proportion of the gases in charcoal vapor when this was in such a condition as to prove fatal to animal life. The vapor was conducted from some fully ignited fuel into an inclosed space in which there was a middle-sized dog whose condition could be watched. In ten minutes the animal fell exhausted, and in twenty minutes it died, after some hard breathing. A candle burnt with its usual brightness in the closed room, and it was only ten minutes after the death of the dog, that the flame of the candle, from becoming paler and paler, was extinguished. The air of the chamber was at this time collected and analyzed; it contained, in 100 parts—carbonic acid, 4.61; carbonic oxide, 0.54; carburetted hydrogen, 0.04; oxygen, 19.19; and nitrogen, 75.62. It would thus appear that less than 5 per cent. of carbonic acid is fatal to life when so little as $\frac{1}{2}$ per cent. of carbonic oxide is mixed with it. (Bernard, op. cit. p. 159.) The burning of a candle under the circumstances, will also show that oxy-combustion may be maintained in a mixture by which an animal is killed, and, therefore, that combustion can furnish no criterion of safety in apartments in which charcoal has been burnt.

Symptoms and appearances after death.—The following case, illustrating the effects of charcoal-vapor, occurred to Mr. Collambell. ("Med. Gaz.," vol. 27, p. 698.) In January, 1841, a man was engaged to clean the windows of three small rooms on the basement-floor of a house. The first room had a door opening into a court-yard; the others merely communicated with each other by a central door, and there was no fire-place in any one of them. A brazier of burning charcoal had been placed in the outer room for the purpose of drying it, but it appeared that the deceased had shut the outer door, and had removed the brazier into the inner room of the three, leaving the communicating doors open. In *two hours* the man was found quite dead, lying on the floor of the middle room. The countenance was pale, as well as the whole of the skin; the eyes were bright and staring, the pupils widely dilated, the lips bloodless, the jaws firmly fixed, the tongue protruding; and the face and the limbs were cold. Some frothy mucus had escaped from the mouth. The person who discovered the deceased, found the ashes in the brazier still burning, and he experienced great oppression in breathing. An inquest was held, but without an inspection of the body, and a verdict of "accidental death" returned. The body was afterwards privately inspected by Mr. Collambell. On opening the head, the vessels on the surface of the brain were found much distended with dark liquid blood; the pia mater was bedewed with serum. The brain was of unusually firm consistency, and numerous bloody points appeared on making a section of it. The lateral

ventricles were distended with about an ounce and a half of pale serum, and the vessels of the plexus choroides were much congested. The cerebellum was firm, and presented on section numerous bloody points. About two ounces of serum, tinged with blood, were collected from the base of the skull. The lungs had a slate color. On the left side of the chest there were eight ounces of serum, tinged with blood, and nearly an equal quantity on the right side. On cutting into the organs, a large quantity of serous fluid mixed with blood escaped. The bronchial tubes were filled with a frothy fluid tinged with blood. The pericardium contained an ounce of pale serum; the heart was enlarged—its cavities contained no blood; the liver and kidneys were, however, much gorged. There was no doubt that the cause of death was the inhalation of charcoal-vapor; and it is probable that the man died from respiring but a comparatively small proportion. The capacity of the chambers must have nearly reached two thousand cubic feet; the deceased had been there only two hours, and when the person who discovered him entered the rooms, the air was not so vitiated but that he could breathe, although with some oppression. The fuel was then in a state of combustion.

In a case of death from charcoal-vapor, which was referred to me for examination in 1851, there was a considerable effusion of blood in the submucous tissue of the stomach. This appearance led to a strong suspicion of irritant poisoning. A full investigation of the circumstances, however, showed that the suspicion was unfounded. The vapor had descended through a flue communicating with the bedroom in which the deceased slept with her husband; it destroyed the wife, and nearly killed the husband. A stove with burning charcoal had been placed in the room above that in which the couple slept, and an iron pipe conveyed the products of combustion into a flue, whence they descended into the bedroom and caused the fatal accident. It is sometimes difficult to account for the mode by which these gaseous mixtures find their way into an apartment. In the above-mentioned case there was great difficulty in procuring correct information. There was no fire in the bedroom, or any source of combustion, and this at first strengthened the suspicion that the husband must have poisoned the wife at their supper on the previous night. M. Devergie relates a somewhat similar case, in which the wife was found dead in bed, while the husband, lying by her side, was in a state of unconsciousness, from which he did not recover until the next day. In this instance there was no stove or fire, or any source of combustion in the room. The noxious gases must have leaked into the room through fissures in a chimney adjoining it. ("Ann. d'Hyg.," 1871, 2, 441.) Dr. Parker met with two cases of suffocation by carbonic acid. A mother and daughter went to bed. In the morning, the daughter was found on her face dead—the face livid, and there had been copious bleeding from the nose. The mother was insensible, and recovered only after many hours under treatment. The cause of the accident was traced to an imperfect joint in a furnace-flue, which passed through the bedroom to a chimney. This adjoined their bed, and the leakage took place directly upon them. The door was shut, and the smell, perceived at first, was supposed to come in from the outside. ("Med. Gaz.," vol. 47, p. 412.) In the case of a youth, æt. 17, M. Guérard found the mouth and

nostrils filled with froth. The liver and spleen were gorged with dark liquid blood; the heart was collapsed, and its cavities were empty, but liquid and dark-colored blood flowed from the large vessels. The wind-pipe and bronchi had a red color, and were filled with frothy mucus. The membranes of the brain were congested, and the sinuses gorged with fluid blood. The face was pale, the eyelids were closed, and the pupils natural. There were livid patches over the body. ("Ann. d'Hyg.," 1843, vol. 2, p. 57.)

It often excites surprise on these occasions that no exertion has been made to escape, when it would apparently require but slight efforts on the part of the person affected. The action of this vapor is very insidious; one of its first effects is to create an utter prostration of strength, so that even on a person awake and active, the gas may speedily produce a perfect inability to move or to call for assistance. For a case illustrative of the dangerous effects of the diluted vapor, see "Ed. Med. and Surg. Journ.," vol. 1, p. 541. In this instance, a charcoal brazier was left, only for a short time, in the cell of a prison. It was removed, and the prisoners went to sleep. They experienced no particular effects at first, but after some hours two were found dead. Thus, then, an atmosphere which can be breathed for a short time with impunity, may ultimately destroy life.

M. Devergie has shown that the smothered combustion of *wood* may lead to the evolution of a noxious vapor (carbonic oxide), and give rise to dangerous consequences. ("Ann. d'Hyg.," 1835, vol. 1, p. 442.) His remarks have been recently confirmed by two cases published by MM. Bayard and Tardieu. A man and his wife were found dead in bed. There was a smoky vapor in the apartment, but no fire had been lighted in the grate, and the chimney was blocked up. The planks of the floor were widely separated, and there was a large hole in the boards at the foot of the bed, communicating with the apartment below. It was found, on examination, that some joists connected with the flue of an iron plate, which had been heated for making confectionery the previous day, were in a smouldering state; that the vapor had entered the bedroom of the deceased through the crevices in the floor, and not finding a vent by the chimney, had led to these fatal results. It is remarkable that the source of combustion was nearly nine yards distant, and one person who slept nearer to the flue of the iron plate, entirely escaped. In the body of the husband the skin was of a reddish tint, the blood liquid, the cavities of the heart empty, the lungs gorged, and there were no subpleural ecchymoses. In the body of the wife there was less redness of the skin, the blood was coagulated in the cavities of the heart, principally on the right side, extending to the vessels; less engorgement of the lungs, and a great number of subpleural ecchymoses, indicating that strong efforts had been made to respire. There was at first a rumor of poisoning, which was only removed by a close examination of the locality. ("Ann. d'Hyg.," Oct. 1845, p. 369.)

Dr. Schauenburg has published the cases of two children who were destroyed in an hour by the vapor of burning wood. The mother had accidentally shut them up in a room into which the vapor leaked from the

wood employed to heat an oven. In each case the brain and its membranes were found highly congested, while the lungs were collapsed, and contained no more blood than is usually found in them. (Eulenberg, "Vierteljahrs.," 1872, 1, 40.) It may be observed in reference to this vapor that when produced from burning charcoal or wood—in spite of the great density of carbonic acid, the noxious gas is diffused rapidly throughout the whole of an apartment. This is owing partly to the effect of the heated current of air, and partly to the law of the diffusion of gases, whereby heavy and light gases are soon uniformly intermixed.

Vapor of gunpowder.—The vapor of exploded gunpowder is chiefly a mixture of nitrogen with carbonic acid and the vapor of sulphide of potassium. When fired in a close place, where there is no ventilation, gunpowder expels the air containing oxygen, and substitutes for it a mixture of gases not fitted to support life. The effects of such a mixture when breathed may be gathered from the following cases communicated to me in August, 1873, by Dr. F. P. Smith, of Shepton Mallet. A boy, æt. 14, went down a well immediately after a considerable charge of powder had been exploded in it. He dropped suddenly to the bottom of the well, and a man who followed him also dropped apparently lifeless. They were both drawn up as soon as possible. The man appeared stupefied, but speedily recovered. The boy was quite unconscious, was blue about the lips, almost pulseless, had epileptic convulsions, and appeared to be dying. He vomited much biliary and mucous fluid, and became worse after removal from the open air to the hospital ward. His breathing was loud, but air entered the lungs freely. The pupils were natural. He did not recover until after thirty-six hours. Artificial respiration was used, and warm water baths were applied to the feet.

CARBONIC OXIDE.

The noxious effects of the vapor of burning charcoal are considered to be partly due to the presence of carbonic oxide. It appears to be chiefly extricated under a low or smouldering combustion of any kind of woody fibre. Mr. Sells, of Guildford, has given me an account of the deaths of five horses from the smouldering combustion of litter in a stable, in which they had been placed for the night. The symptoms were oppressed breathing, feebleness, tremblings, and inability to swallow. It is fatal to man and all animals. The action of this gas upon animal life has been made a subject of experiment by Bernard ("Leçons sur les Substances Toxiques," p. 164.) An atmosphere containing from 5 to 6 per cent. of it will destroy life. The blood and muscles are brightened in color by this gas, while they are darkened by carbonic acid. Bernard has observed that this bright color has been retained for three weeks; and he considers the mode of action of this gaseous poison such, that it prevents the arterial blood of the body from becoming venous, while carbonic acid operates by preventing the venous blood from becoming arterial. (Op. cit. pp. 182, 195.)

This condition of the blood as a result of the action of carbonic oxide, may occasion some doubt of the cause of death, in cases of suffocation

by fire. In April, 1858, an inquiry took place into the cause of death of fourteen persons, owing to a fire in a house in Bloomsbury. The medical witness, on examining the bodies, found a redness of the muscles and a redness of the blood. He therefore thought that death was not caused by suffocation, but from the inhalation of arsenical vapors, owing to some minerals containing arsenic having been partially consumed during the fire. But there was a total want of evidence to show that the vapors of arsenic, when breathed, would cause death so speedily as the noxious gases evolved by fire, or that they would redden the blood and muscles. On the other hand, the respiration of carbonic oxide would explain these facts. It is worthy of remark that in many of the observed cases of death from charcoal-vapor, the blood has had a darker color than natural: the greater solubility of carbonic acid, and the larger proportion in which it is produced, may account for this effect.

The action of carbonic oxide on the body is that of a pure narcotic poison. M. Tourdes has ascertained that rabbits died in twenty-three minutes, when kept in an atmosphere containing 1.15th of its volume of pure carbonic oxide; when the proportion was 1.30th they died in thirty-seven minutes, and when 1.8th in seven minutes. Dr. Letheby states that in his experiments a mixture of $\frac{1}{2}$ per cent. killed small birds in three minutes, and of $1\frac{1}{2}$ per cent. in about half this time. The animals showed no sign of pain: they fell in a state of insensibility, and either died at once without convulsions, or they gradually passed into a state of profound coma. He found, on inspection, that the blood was redder than usual, that the muscles of the heart were somewhat gorged, and that the brain was congested. ("Lancet," March 1, 1862, p. 219). This gas is very fatal to man. ("Ann. d'Hyg.," Aug. 1879, p. 184.) Dr. Hoppe-Seyler states that animals which had been made to breathe carbonic oxide, were restored by artificial respiration continued for some time, and under these circumstances, the gas was expired as carbonic acid, having undergone further oxidation in the blood. This writer has suggested a method for detecting the presence of carbonic oxide in the blood by spectral analysis. ("Chem. News," Aug. 4, 1865, p. 58.) According to some recent observations, carbonic oxide is eliminated from the lungs as such without being converted into carbonic acid. ("Lancet," 1873, 1, p. 741.)

It is a remarkable fact that with the bright red color of the blood seen in this form of poisoning, two absorption-bands similar to those of oxy-hæmoglobin appear, and nearly in the same situation. They are further removed from the line D, and are more in the greenish-yellow rays. A reducing agent (alkaline sulphide) does not affect these bands, as it does those of oxidized blood. Dr. Wesche found, however, that this optical method can seldom be of any practical use, for the combination of the gas with the coloring matter of blood was so slight, that it speedily escaped from it. Hence, if the person breathes for only a short time, the carbonic oxide is expelled. In poisoning by coal-gas, carbonic oxide appears to be sometimes the direct cause of death. It is always a constituent of this gas, but in variable proportion. (See p. 505.) M. Grehan has lately published his observations on the

absorption and diffusion of carbonic oxide in the blood. ("Ann. d'Hyg.," Aout, 1879, p. 97.)

COAL AND COKE VAPORS. SULPHUROUS ACID.

Products from burning coal and coke.—The gases extricated in the smothered combustion of coal or coke are of a compound nature. In addition to carbonic acid, carbonic oxide, and tarry vapors, we may expect to find in the atmosphere of a close room in which such a combustion has been going on, SULPHURIC ACID GAS; and from coal, in addition to this, the sulphuretted and carburetted hydrogen gases. These emanations are equally fatal to life; but in consequence of their very irritating properties they give warning of their presence, and are therefore less liable to occasion fatal accidents. From an accident which occurred at Colchester a few years since, in which two children lost their lives, it would appear that some persons are so ignorant as to believe that the vapor of coke is less fatal than the vapor of charcoal. The sulphurous acid gas, when existing in a small proportion in air, has the effect of irritating the air-passages so violently that, if accidentally breathed, it would commonly compel the person to leave the spot before the vapors had become sufficiently concentrated to destroy life. Nevertheless, accidents from the combustion of coal and coke sometimes occur. Two cases showing the noxious effects of the vapor of coke will be found reported in the "British Medical Journal," for March 13, 1875.

Symptoms and appearances.—The following cases will convey a knowledge of the symptoms and appearances which may be met with on these occasions. Some years since four persons, in a state of asphyxia, were brought into Guy's Hospital. It appeared that on the previous evening they had shut themselves up in the fore-castle of a coal-brig, and had made a fire. About six or seven o'clock on the same evening, some of the crew accidentally placed a covering over the flue on the outside, and thus stopped the escape of smoke from the fire, which was made of a kind of coal containing much sulphur. Early in the morning one of the crew, on opening the hatches, observed three of the inmates lying on the floor senseless and frothing at the mouth, and the fourth in his crib in a similar condition. The air in the place was most offensive. After the men were brought on deck one of them, aged twenty-one, began to recover, and when brought to the hospital he seemed only giddy, as if intoxicated: he soon completely recovered. Another, aged forty, after breathing oxygen-gas and having brandy and ammonia administered to him, showed no symptoms of recovery, but died in a few hours. A third, aged seventeen, soon began to rally, and in a short time he was able to answer questions; he declared that at the time of the accident he felt no pain, sense of oppression, or weight, either in his head or chest. The fourth, aged fifteen, died the following day, having shown no symptoms of rallying. Stimulants were administered, and warm fomentations were used, but all efforts to produce reaction failed. The appearances presented by these persons when brought in, were as follows: The lips were purple, the countenance was

finer in a close apartment, where the air is not subject to change or renewal, while the products of respiration are accumulated; and the effects are hastened when a number of persons are crowded together in a small space. The change which air, thus contaminated by breathing, undergoes may be very simply stated. The quantity of nitrogen in 100 parts will remain nearly the same; the quantity of oxygen will probably vary from 8 to 12 per cent., while the remainder will be made up chiefly of carbonic acid. If many persons are crowded together, the air will acquire a high temperature, and it will be saturated with aqueous vapor which contains decomposing animal matter derived from the lungs and skin. From this statement, it is evident that air which has been contaminated by continued breathing, will operate fatally on the human body, partly in consequence of its being deficient in oxygen, and partly from the noxious effects of the carbonic acid contained in it. The proportion in which carbonic acid exists in respired air is subject to variation: according to the experiments of Allen and Pepys, it never exceeds 10 per cent. by volume of the mixture, how frequently soever it may have been received into and expelled from the lungs. The influence of respiration on air may be thus stated:—An adult consumes from one to two gallons of air per minute, and the air expired contains from 4 to 5 per cent. of carbonic acid; but it is a remarkable fact that, when a person continues to breathe the same air, the proportion of carbonic acid expelled is reduced at each successive expiration. When the amount in air has reached 10 or 12 per cent. no more is thrown off by the lungs, and the blood is no longer depurated. For healthy existence, an adult requires 20 cubic feet, or 125 gallons, of air per hour. A common candle will consume as much as two gallons of air per minute, or render that quantity of air unfit for breathing.

These facts are of importance in reference to the size of bedrooms occupied by the poorer classes. The rooms are often small, without ventilation by door, window, or chimney, and fatal accidents, especially to children, are likely to arise from a number sleeping in the same room. The late Dr. Parkes calculated in reference to sleeping-rooms, that the minimum cubic space required for boys and girls from fourteen to sixteen years of age should not be less than 500 cubic feet, and above that age from 600 to 800 cubic feet should be allowed per head. In November, 1878, a woman and six children were found dead in their bedroom at Liverpool. The whole capacity of the room was only equal to 512 cubic feet, *i. e.*, about sufficient for one person. In this case a bucket with burning coke (see p. 502) had been placed in the centre of the room, the door and windows closed, and no flue to carry off the coke-vapor. This, no doubt, was the principal cause of death, as the coke must have rapidly exhausted the small quantity of air in the room.

Dalton found that the air in crowded rooms, such as theatres, contained one per cent. of carbonic acid, the atmospheric proportion (1-2500th) being therefore increased twenty-fivefold. I have found a similar proportion in the impure air taken from Cornish mines, at a depth of about 1400 feet. The coarse candles used by miners vitiate as much air as the breathing of an adult, and there is an absence of any proper means of ventilation. It is certain that insensibility and death would ensue in

a human adult before the whole of the oxygen of the confined air had disappeared; but the opportunity can rarely present itself of analyzing such a contaminated mixture, and hence it is impossible to specify the exact proportion in which carbonic acid would exist when the confined air proved fatal to persons who had respired it. M. Lassaigne has shown, by direct experiment, that the carbonic acid in the air of close rooms does not gravitate to the floor, but is equally diffused throughout. The whole mass of air is in fact vitiated, and requires renewal. ("Med. Gaz.," vol. 38, p. 351; see also "Report on Mines," 1864, App. B, p. 196, and "Chemical News," Feb. 17, 1865, p. 79.)

COAL-GAS. CARBURETTED HYDROGEN.

Coal-gas is a compound which acts directly as a poison when respired. Many fatal accidents have occurred from the respiration of air contaminated with it. Its composition is subject to much variation, according to circumstances. Mitscherlich found that it was principally composed of light carburetted hydrogen, hydrogen, and carbonic oxide, in the proportion of 66 per cent. of the first, 21·3 of the second, and 11 of the third. M. Tourdes found that the proportions of light carburetted hydrogen and carbonic oxide were nearly equal, *i. e.*, about 22 per cent. An analysis of coal-gas as supplied to London shows that in 1000 parts it contains—of hydrogen, 464·3; of light carburetted hydrogen, 389·3; carbonic oxide, 56·2; olefiant gas, 38·6; watery vapor, 24·8; nitrogen, 22·2; carbonic acid, 4·6. The difference in composition depends on the heat to which the gas has been submitted. Dr. Poleck has recently (1878) found, in four series of experiments in which death was caused in rabbits by the gaseous products of combustion of pit-coal, that the air of the chamber had a mean composition in 100 parts of 6·56 carbonic acid, 0·46 carbonic oxide, 13·4 oxygen, and 79·58 nitrogen. In experiments made with coal-gas, the gaseous mixture which caused the death of the animal was always found explosive. He agrees with many others that carbonic oxide is the poisonous agent in coal-gas, except in those cases in which it is largely contaminated with sulphuretted hydrogen-gas. In poisoning by charcoal vapor the effects are due to carbonic acid, carbonic oxide, and the diminution of oxygen. There is no doubt that the hydrocarbons also have a specially noxious influence, although the use of the safety-lamp in mines proves that a mixture of light carburetted hydrogen with air in an explosive proportion, may be breathed for a certain time without producing serious effects.

Symptoms and appearances after death.—The symptoms produced by coal-gas, when mixed in a large proportion with air, are—giddiness, headache, nausea with vomiting, confusion of intellect, loss of consciousness, general weakness and depression, partial paralysis, convulsions, and the usual phenomena of asphyxia. The appearances after death will be understood from the following cases. In January, 1841, a family residing at Strasburg breathed for forty hours an atmosphere contaminated with coal-gas, which had escaped from a pipe passing near the cellar of the house in which they lodged. On the discovery of the accident four of the family were found dead. The father and mother still breathed,

but, in spite of treatment, the father died in twenty-four hours: the mother recovered. When the five bodies were inspected there was a great difference in the appearances; but the principal changes observed were, congestion of the brain and its membranes,—the pia mater (inner membrane) being gorged with blood, and the whole surface of the brain intensely red. In three of the cases there was an effusion of blood (coagulated) on the dura mater and in the spinal canal. The lining-membrane of the air-passages was strongly injected, and there was spread over it a thick viscid froth tinged with blood; the substance of the lungs was of a bright-red color, and the blood in the vessels was coagulated. (“Ann. d’Hyg.,” Jan. 1842.) In two cases communicated by Mr. Teale to the “Guy’s Hospital Reports” (No. 8), there was found congestion of the brain and its membranes, with injection of the lining-membrane of the air-passages; the blood was remarkably liquid. An aged woman and her granddaughter, who had been annoyed by the escape of gas during the day, retired to bed, and they were found dead about twelve hours afterwards. In April, 1873, four members of a family were found dead in their bedroom at Dundee. The mother, father, and two children had retired to rest quite well. There was a strong smell of coal-gas on entering the room, and they had undoubtedly died from the effects of this gas while sleeping. Gas had been formerly supplied to the house, but it had been carelessly cut off, and a portion still leaked into the room. (“Med. Journal,” 1879, vol. 1, p. 22.) These facts show that life may be insidiously destroyed by the breathing of this gas without giving the slightest warning.

In the cases above related, the effects produced by coal-gas were owing to the long-continued breathing of it in a diluted state. The quantity contained in the air of the rooms must have been very small: in M. Tourdes’s case it was probably not more than 8 or 9 per cent., because at a little above this proportion the mixture with the air becomes explosive; and there had been no explosion in this case, although in the apartment in which the persons were found dead, a stove had been for a long time in active combustion, and a candle had been completely burnt out. In Mr. Teale’s cases those who first entered the house perceived a strong smell of coal-gas, but still the air could be breathed.

Mr. Bloxam has published a case of poisoning by coal-gas, which shows how easily life may be destroyed by it. The appearances in the body are more fully described than usual. In November, 1861, Mr. Bloxam saw the deceased, who was a gasfitter; his body was supported in a sitting posture on the floor. The man had accidentally breathed coal-gas mixed with air, while connecting a tube with a meter. The skin was cold, the cornea glazed, and the face pale and placid: there was some froth about the mouth, the pupils were rather dilated, and the limbs supple. There was a strong smell of gas in the place. He was working in a closet, and he was found insensible on the top of a pair of steps in a sitting posture,—his head on one side, his arms hanging down, and his back leaning against the wall, in the attitude in which he had been engaged at his work. He had evidently died quietly and placidly on his seat, and had made no attempt to descend the steps. He was last seen alive an hour before he was found dead, and he no doubt died rapidly

from the inhalation of the gas. An inspection of the body was made about twenty-four hours after death. The skin of the face and upper part of the body was pale,—rigidity was well-marked, and there was general lividity of the back of the body as well as of the limbs. The blood was everywhere fluid. The brain and its membranes were not congested, but were rather pale than otherwise; the ventricles contained a pale serum. There was a strong odor of coal gas on exposing the brain. The lungs were of a dark-red color, and did not collapse on raising the chest-bone; they were dark at the back of the lobes from gravitation of blood; their structure was healthy. The windpipe and bronchi contained frothy mucus in some quantity. A powerful odor of gas was perceived on compressing the lungs. The heart was healthy; the right cavities were distended with blood, and the left were nearly empty; the blood was everywhere dark-colored. There was congestion of the abdominal viscera, but no other unusual appearances. (“*Med. Chir. Trans.*, 1862, vol. 45, p. 103.) In general the smell of gas may be perceived in the breath of some time after the person has been removed from the noxious atmosphere. In the *Chantrelle* trial at Edinburgh, May, 1878, the time for the disappearance of the odor in a person still living was an important question. There are but few facts recorded on this subject. In one case, where sensibility was completely lost, the smell of the gas had entirely disappeared from the breath in two hours and a half after the man's recovery. (“*Lancet*,” June 1, 1878, p. 786.)

Coal-gas, like other aërial poisons may destroy life if long breathed, although so diluted as not to produce any serious effects in the first instance! This gas owes its peculiar odor to the vapor of naphtha; the odor begins to be perceptible in the air when the gas forms only the 1000th part, it is easily perceived when forming the 700th part, but the odor is strongly marked when it forms the 150th part (Tourdes). In most houses in which gas is burnt, the diluted odor, owing to leakage, is plainly perceived; and it is a serious question whether health and life may not often be affected by the long-continued breathing of an atmosphere containing but a small proportion. The odor will always convey a sufficient warning against its poisonous effects. It should be known that this gas will penetrate into dwellings in an insidious manner. In Mr. Teale's cases, the pipe from which the gas had escaped was situated about ten feet from the wall of the bedroom where the women slept; the gas had permeated through the loose earth and rubbish, and had entered the apartment through the floor. I have notes of several other cases in which coal-gas has thus destroyed life by slow leakage into bedrooms. In one of these (January, 1878) a gas-pipe passing under the floor had been left imperfectly stopped during repairs. This led to the death of two ladies sleeping in the room above with closed door and windows. In another, the leakage was owing to a carpenter hammering nails through the floor. Some of these had penetrated a concealed gas-pipe, and led to an escape sufficient to prove fatal to a person sleeping in the room. In a third case, a leakage had been caused by rats gnawing a hole in the thin pewter pipe in which gas is conveyed in houses. Four persons suffered severely by this accident, and barely escaped with their lives.

Dr. Layet has recently directed attention to the circumstances under which coal-gas is liable to penetrate into the apartments of dwellings not supplied with gas, and thus to cause fatal accidents. The great tension of the gas during winter, the permeability of the soil, and the effect of aspiration in heated rooms, sufficiently account for these results wherever there is any leakage. ("Ann. d'Hyg.," March, 1880, p. 255.)

There is another cause of leakage which may lead to accident. When gas is burnt the whole of the night in a closed bedroom, the flame may be extinguished by a current of air, or by a withdrawal of pressure. This would lead to a subsequent escape, which might prove fatal. The action of this gas on the brain and nervous system is so insidious, that the person is rendered powerless before he is conscious of danger.

It is impossible to determine exactly what proportion of this gas in air will prove fatal. An atmosphere containing from 7 to 12 per cent. has been found to destroy dogs and rabbits in a few minutes; when the proportion was from $1\frac{1}{2}$ to 2 per cent. it had little or no effect. With respect to man, it may destroy life if long respired when forming about 9 per cent., *i. e.*, when it is in less than an explosive proportion. (See "British and Foreign Med. Rev.," vol. 20, p. 253; also "Ann. d'Hyg.," 1830, vol. 1, p. 457; and "Edinburgh Med. Jour.," July, 1874.) The late Dr. Aldis observed in his experiments that in ordinary coal-gas mixed with air, rats were rendered insensible in half a minute, and died in a minute and a half to two minutes. There was before death a spasmodic action of the diaphragm. The gas was allowed to enter slowly into a bell-jar of air in which the animals were placed. ("Med. and Chir. Trans.," 1862, vol. 45, p. 100.)

The products of combustion of *coal-gas* consist chiefly of carbonic acid and sulphurous and nitric acids. The hydro-carbon vapors of *petroleum*, paraffine oil, kerosene, and other forms of rock oil, produce by combustion large quantities of carbonic acid, and sometimes unburnt vapor. In close rooms these products are fatal to life.

But a person may die from respiring a mixture of unburnt gas as well as of the products of its combustion. It is not unusual to find the gas burning in a room in which a person has been asphyxiated, as in the following case, which occurred at Carlisle in May, 1875. A youth, *æt.* 18, went to bed in a small room without a fireplace or means of ventilation, in which was a sliding gasalier with two jets. He was found in the morning insensible; the sliding gasalier had been drawn down as far as possible, and one of the jets was burning with the cock turned on full. There was a strong smell of unburnt gas in the room, which had escaped from the sliding tube. When seen he was completely comatose, breathing irregularly, face livid, pupils natural and sensible to light, pillow stained with a brownish fluid issuing from the mouth; temperature 102° . In spite of treatment, he continued in much the same state for nearly three days, when the temperature rose to 106° . The pulse was imperceptible, the pupils dilated and insensible. Death took place sixty-eight hours after he was found. On inspection, the vessels of the surface of the brain were full of blood; small clots appeared on making a section of it. The right auricle of the heart was full of dark blood fluid, and coagulated. The surface of the lungs was of a dark claret color, mot-

tled with pink spots. The lungs were full of dark blood, and sections of them presented a mottled appearance, like the pleural surface. The bronchial tubes were free—the inner surface was of a dark purple color. The kidneys were congested. I am indebted for the particulars of this remarkable case to Dr. R. Elliott, coroner for Carlisle. A report of the case has been published by Dr. Lockie. ("British Med. Jour.," September, 1875, p. 392.)

NITROUS OXIDE.

Some recent cases of death from the inhalation of this gas as an anæsthetic, renders a short notice of it necessary in this place. Sir Humphry Davy was the first to show by experiments on himself that, under certain precautions, it might be breathed when mixed with air without danger to life, and that it had the effect of producing an agreeable species of intoxication.

In January, 1873, it was administered by a dentist at Exeter to a lady, æt. 38, at her own desire, in order to annul pain during the extraction of a molar tooth. A physician carefully examined her before the operation, and found that there was nothing to preclude the use of the gas. The nitrous oxide was pure; it had been safely used for other patients from the same condenser, and an apparatus was so arranged as to secure the removal of the expired air. The total quantity administered was about six gallons. This could not be regarded as an overdose. Sir H. Davy himself breathed with safety five gallons in one of his early experiments. Soon after the commencement of the inhalation, it was observed that the pulse became rapid and less full, indicating an action on the heart; the patient was then sensible, and the apparatus was removed. The operation was commenced, but the lady insisted on having the gas again. She took it; insensibility came on, and the operation was completed. Immediately afterwards the face became livid, the features began to swell, and the tongue protruded. In spite of every effort to restore her, she did not recover from the state of insensibility; she breathed two or three times, and the pulse then ceased. No inspection of the body was made. The above-mentioned facts were given in evidence at the coroner's inquest, and the medical opinion was that death had been caused by the gas in producing paralysis of respiration, and that in this case no forethought could have prevented the result. The jury returned a verdict of homicide by misadventure. ("Lancet," 1873, vol. 1, pp. 178, 245, 253.) It has been suggested that on this occasion death may have taken place from suffocation, by blood entering the air-passages; but while there were no symptoms indicative of this, all the facts appear to show that the gas operated as a blood-poison, and destroyed life.

According to the experiments of MM. Joylet and Blanche ("Archives de Physiologie," Juillet, 1873), this gas, when breathed, operates fatally by producing pure asphyxia. The insensibility which is a result of breathing the gas, is, in their view, owing to the nonoxygenation of the blood. It is dissolved in the blood and circulated with it, the blood not having the power to separate the combined oxygen from it. According

to these physiologists, the anæsthetic state produced by this gas is owing to temporary asphyxia, which, in proportion to its duration and the time for which air is cut off, may end in recovery or death. ("Brit. Med. Journ.," Aug. 1873, p. 141.) There is not only a circulation of unaërated blood, but this liquid containing the nitrous oxide in solution, may produce some direct effect on the nerve-centres. [See an excellent paper by Dr. F. D. Weisse, read before the N. Y. Med.-Leg. Society, in "N. Y. Daily Register," Feb. 17, 1873.—R.]

It is evident that much is still to be learned respecting the operation of nitrous oxide on the human body. One experienced administrator contends that air must be occasionally admitted in order to prevent fatal effects, while another states that, according to his experience, the giving of air prevents complete insensibility, and therefore does not fulfil the purpose for which the gas is administered. ("Lancet," 1872, 2, 762.) The nitrous oxide has beyond doubt caused fewer accidents than ether and chloroform; but there is a very narrow line between life and death in the action of this, as well as all anæsthetics; and it should therefore only be given by a skilled administrator.

SULPHURETTED HYDROGEN.

This gas has a more powerful action on the body than either carbonic acid or charcoal-vapor. Persons are sometimes accidentally killed by it; but the very offensive odor which a small portion of it communicates to a large quantity of air is sufficient to announce its presence, and thus, with due caution, to prevent any dangerous consequences. Sulphuretted hydrogen gas, when breathed in its pure state, is instantaneously fatal. It exerts equally deleterious effects upon all animals, and through all the textures of the body, but especially through the lungs.

Symptoms.—The symptoms produced by sulphuretted hydrogen on the human body, vary according to the degree of concentration in which it is breathed. When in a moderately diluted state, the person speedily falls inanimate. An immediate removal to pure air and the application of stimulants, with cold affusion, may, however, suffice to restore life. According to the account given by those who have recovered, this state of inanimation is preceded by a sense of weight in the stomach and in the temples; also by giddiness, nausea, sudden weakness, and loss of motion and sensation. If the gas in a still less concentrated state be respired for some time, coma, insensibility, or tetanus with delirium supervenes, preceded by convulsions or pain and weakness over the whole of the body. The skin in such cases is commonly cold, the pulse irregular, and the breathing laborious. When the air is but slightly contaminated with the gas, it may be breathed for a long time without producing any serious symptoms: sometimes there is a feeling of nausea or sickness accompanied with pain in the head, or diffused pains in the abdomen. These symptoms are often observed to affect those who are engaged in chemical manipulations with this gas. Sulphuretted hydrogen appears to act like a narcotic poison when highly concentrated, but like a narcotico-irritant when much diluted with air. It is *absorbed* into the blood, deoxidizing it and giving it a brownish-black color, in which state it is

circulated through the body. In all cases a noxious atmosphere containing this gas, is indicated by an offensive smell producing nausea and sickness. (For a case of poisoning by it, in which the person recovered, see "Medical Gazette," vol. 43, p. 871.)

Appearances after death.—On examining the bodies of persons who have died from the effects of sulphuretted hydrogen, when breathed in a concentrated form, and the inspection is recent, the following appearances have been observed:—The mucous membrane of the nose and throat is commonly covered by a brownish viscid fluid. An offensive odor is exhaled from all the cavities and soft parts of the body. These exhalations, if received into the lungs of those engaged in making the inspection, sometimes give rise to nausea and other unpleasant symptoms, and may even cause syncope or asphyxia. The muscles of the body are of a dark color, and are not susceptible of the galvanic stimulus. The lungs, liver, and the soft organs generally, are distended with black liquid blood. There is also great congestion about the right side of the heart, and the blood has been found everywhere liquid and dark-colored: the body rapidly undergoes the putrefactive process. When death has occurred from the breathing of this gas in a more diluted form, the appearances are less marked. There is then general congestion of the internal organs, with a dark and liquid state of the blood. In fact, in such cases the appearances can scarcely be distinguished from those produced by carbonic acid. Four men lost their lives in the Fleet Lane Sewer in February, 1861; they were found dead, and there was no doubt that sulphuretted hydrogen was the cause of death. An account of the appearances presented by the bodies is reported in the "Lancet" by Mr. Holden and Dr. Letheby (February 23, 1861, p. 187). The eyes and mouth were open, the lips and tongue livid, the pupils widely dilated, the blood black and fluid, the lungs congested, the heart full of black fluid blood, the right side gorged, and there was a bloody froth in the windpipe. In the brain the large vessels of the dura mater were full of black fluid blood.

In June, 1857, six persons lost their lives, at *Cleator Moor*, near Whitehaven, by the respiration of sulphuretted hydrogen in a diluted form, by reason of their having slept in small close ill-ventilated rooms, into which the gas had penetrated. Three of the deceased persons—a husband, wife, and child, of one family (*Armstrong*)—had retired to rest, in their usual health, on the night of the 9th of June. Two of them were found the next morning dead in bed, and a third (the child) was found in a state of insensibility, and lingered until the afternoon of the same day, when she died. The fourth, a healthy adult, retired to sleep in his bed with his door closed, and he was found dead in *an hour*. The fifth, a child, was taken ill on the morning of the 11th, and died the same day. The sixth was taken ill on the morning of the 10th, and died on the 12th of June.

The symptoms complained of by some who recovered were nausea, sickness, giddiness, and insensibility. On inspection of the body of one child, the pupils were found dilated,—viscid mucus escaped from the nostrils,—there was congestion of the lungs and kidneys, as well as of the membranes of the brain. In the adult who died in an hour, the pupils

were natural, the jaws firmly clenched, the fingers contracted, and the nails blue ; there was great cadaveric lividity, and a quantity of fluid with frothy mucus issued from the nostrils and mouth. The lungs were much congested, and serum was effused in the cavity of the chest. The heart contained a little fluid blood, and was somewhat flaccid. The mucous membrane of the windpipe and gullet was redder than natural, and in the former there was frothy mucus. The stomach, as well as the large and small intestines, were highly congested but otherwise healthy. The brain and its membranes were greatly engorged with blood, which, as in the body generally, was very dark and fluid. The late Mr. J. B. Wilson, who examined the body of the child, drew the conclusion, which was confirmed by the subsequent inquiry, that death had been caused by sulphuretted hydrogen. Dr. Thompson, who examined the body of the man, also inferred that some noxious gas or gases had destroyed life. Having been required by the Home Office to investigate the cause of death in these cases, I visited Cleator on the 22d of June, and found that the cottages in which the accidents had occurred, were built upon a heap of iron-slag, which also abutted on the premises behind. The slag contained, among other matters, sulphide of iron and sulphide of calcium. A foul smell, compared to that of cinders extinguished by water, had for some time been perceived about the rooms, chiefly at night when the doors and windows were closed ; and the day before the occurrence a heavy storm of rain had washed through the slag-heap, and aggravated the effects. The heap of slag was burning in certain parts, and sulphuretted hydrogen was evolved in large quantities at a depth of a few feet below. At the time of my visit, *i. e.*, a fortnight after the deaths, on removing the stone pavement in the lower rooms, the slag below was found damp, and sulphuretted hydrogen was still issuing from it. The white-lead paint in the closets was partly converted into black sulphide, and this chemical change was found in patches on the chamber-door of one small room in which two persons had died.

The symptoms, so far as they were observed in the living, the appearances in the dead bodies, and the chemical nature of the wet slag beneath the foundation, left no reasonable doubt that during the night, with the doors and windows closed, sulphuretted hydrogen had escaped in sufficient quantity to poison the air and destroy life, and a verdict was returned to this effect. A suggestion was made that carbonic acid might have caused the symptoms and death, but there was no source of carbonic acid but the breath ; and there is, I believe, no instance known of any adult having breathed himself to death in an hour, in a room containing 600 cubic feet of air,—not to mention that persons had slept in similar rooms in the same row of cottages, at a distance from the slag-heap, without perishing from such a cause. Another theory was put forward, to the effect that carbonic oxide in the vapors of some blast-furnaces had found its way into the rooms where these persons had died ; but the nature of the locality and the distance of the furnaces rendered this impossible. Persons who had left their windows open, whereby these vapors might have entered, escaped, while the deaths occurred only in those houses in which the doors and windows were completely closed. It is highly probable that the sulphuretted hydrogen was mixed with other gases and

vapors, as it is never found pure except in a chemical laboratory ; but the circumstances proved left no doubt that this gas was the principal agent of death. This seems to have been clearly established by the fact, that after a channel for drainage had been cut through the slag-heap and the slag removed, no casualty took place.

As in reference to carbonic acid, an atmosphere which may be breathed for a short time with impunity will ultimately destroy life. Sulphuretted hydrogen in a fatal proportion, however diluted or mixed with other vapors, would always be indicated by a disagreeable smell ; although from habit, as well as probably from the effects of the gas on the nervous system, this offensive smell might not be perceived when a person had remained for a short time in the poisoned atmosphere. In the cases of the *Halls*, which occurred at Sheffield in 1852, there is reason to believe that the deaths of two persons were caused by the smouldering of ashes in a cesspool ("Association Medical Journal," April, 1853, p. 280). Mr. Haywood considered that carbonic acid was the agent in this case, although it is probable, from the nature of the materials in which combustion was going on, that sulphuretted hydrogen and other gases and vapors were simultaneously evolved.

Effluvia of drains and sewers.—The most common form of accidental poisoning by sulphuretted hydrogen (for it is rare that a case occurs which is not purely accidental) is witnessed among nightmen and others who are engaged in cleaning out drains and sewers, or in the removal of nightsoil. These accidents are much more frequent in France than in England, the soil being often allowed to collect in such quantities in Paris and other large continental cities, as to render its removal a highly dangerous occupation for the workmen. According to the results of Thénard's observations, there are two species of compound gases, or mechanical mixtures of gases, which are commonly met with in the exhalations of privies. The first compound consists of a large proportion of atmospheric air holding diffused through it in the form of vapor, the *hydrosulphate of ammonia* (sulphide of ammonium). The hydrosulphate is contained abundantly in the water of the soil, and is constantly rising from it in vapor, and diffusing itself in the surrounding atmosphere. It is this vapor which gives the unpleasant and pungent odor to the effluvia, and causes an increased secretion of tears in those who unguardedly expose themselves to such exhalations. The *symptoms* produced by the respiration of this gaseous mixture, when in a concentrated state, bear a close resemblance to those which result from the action of sulphuretted hydrogen gas. If a person is but slightly affected, he will probably complain of nausea and sickness: his skin will be cold, his respiration free but irregular; the pulse is commonly frequent and the voluntary muscles, especially those of the chest, are affected by spasmodic twitchings. If more strongly affected, he loses all power of sense and motion; the skin becomes cold, the lips and face assume a violet hue, the mouth is covered by a bloody and frothy mucus; the pulse is small, frequent, and irregular; the breathing hurried, laborious, and convulsive; and the limbs and trunk are in a state of general relaxation. If still more severely affected, death may take place immediately; or should the person survive a few hours, in addition to the above symptoms, there

will be short but violent spasmodic twitchings of the muscles, sometimes even accompanied by tetanic spasms. (See "Ann. d'Hyg.," 1829, vol. 2, p. 70.) If the person is sensible he will commonly suffer severe pain, and the pulse may become so quick and irregular that it cannot be counted. When the symptoms are of such a formidable nature, it is rare that a recovery takes place. The *appearances* met with on making an examination of the body are similar to those observed in death from sulphuretted hydrogen. The inspection should be made with caution, for a too frequent respiration of the poisonous exhalations may seriously affect those who undertake it. (See a paper by Dr. Perrin, "Ann. d'Hyg.," 1872, vol. 2, p. 73.) The admixture of any mineral acid with the sewage liquid containing sulphide of ammonium produces an immediate escape of sulphuretted hydrogen in fatal proportion. This operates more speedily than the mere agitation of the liquid. In August, 1876, a man lost his life in a London sewer owing to the sudden influx of refuse acid liquid from a factory, which caused a sudden escape of the poisonous gas.

The fluid matter of cesspools is generally saturated with this gas, and contains much sulphide of ammonium, which is always escaping from it in vapor. This fluid is noxious, and if swallowed in quantity may cause death.

The following case, which has some relation to this subject, occurred in London in 1831: Twenty-two boys, living at a boarding-school at Clapham, were seized in the course of three or four hours with alarming symptoms of irritation in the stomach and bowels, spasms of the muscles of the arms, and excessive prostration of strength. One child, that had been similarly attacked three days before, died in twenty-five hours, and one among the last attacked died in twenty-three hours. Both of the bodies were examined after death: in the first the mucous glands of the intestines were found enlarged and, as it were, tuberculated; in the second the mucous coat of the small intestines was found ulcerated, and that of the colon softened. At first, it was suspected that the boys had been poisoned, but an analysis of the food did not lead to the discovery of any noxious substance. The only circumstance which was considered sufficient to explain the accident was, that *two days* before the first child was seized, a foul cesspool had been opened, and the materials diffused over a garden adjoining the children's play ground. This was the source of the noxious effluvia, according to the opinion expressed by six medical practitioners. ("Christison on Poisons," p. 810.)

[The epidemic which affected so many of the visitors of the National Hotel in Washington, D. C., during the winter and spring of 1857, and well known in the United States as the "National Hotel Disease," affords a remarkable illustration of this form of atmospheric poisoning, in which a large number of persons of both sexes were attacked with violent irritation of the alimentary canal, generally of the large intestines,—many having died, after variable periods of illness, and in some instances, after repeated relapses. The symptoms of irritation of the stomach and bowels presented so generally by the guests of this hotel, at a time of high political excitement, gave rise to a suspicion of metallic poisoning, which for a while became the popular belief. The evidence presented at the inquest of the local Board of Health, however, entirely contradicted this

theory, and showed not only that no irritant poison could have been used in the food, and that the symptoms were not those of metallic irritation, but that they were those of poisoning by sewer emanations; and that such emanations had been present to a dangerous extent in the most frequented parts of the house, during the whole of the three months of the epidemic visitation. The officers of the Board of Health discovered a stream of sewer gas which was flowing through a defective inlet, from a badly working culvert directly into the cellar of the hotel, with force enough to extinguish a lighted candle. Abundant evidences from other sources, equally indisputable, might be presented in corroboration. Repeated instances occurred of individuals being taken ill after a visit to the hotel, who had neither eaten nor drunk anything while in the house; and the offensive smell observed about the building, especially in the lower rooms, had been very generally observed. This fœtor was aggravated during the prevalence of cold weather, at which time the windows and doors were closed, and the disease increased in violence. The pathological condition was ascertained to be that of ulcerative diarrhœa, "a superficial erythematous or catarrhal inflammation of the mucous membrane of the colon." We have witnessed this peculiar effect of cesspool exhalations in various degrees, so frequently among prison convicts, that we were satisfied as to its true origin, before the investigations had been undertaken to contradict the erroneous hypothesis of poisoned food or drink. An epidemic of diarrhœa and general intestinal irritation, the exact counter-part of the National Hotel disease, might at any time be developed among the inmates of our prisons by a neglect of the usual cleansing of the privy pans and pipes. See on this subject, "Am. Journ. of Med. Sci.," Jan. 1858, p. 97; "Boston Med. and Surg. Journ.," vol. lvi., 1857, pp. 305, 371, 422; "New York Journ. of Med.," July, 1857, p. 90; "Virg. Med. and Surg. Journ.," vol. viii., 1857, pp. 478, 514; "Trans. Coll. of Phys. of Philada.," New Series, vol. iii. No. 3, 1857, p. 128.—H.]

Analysis.—The recognition of these gases and vapors is a simple operation. The odor which they possess is sufficient to determine their presence, even when they are diluted with a large quantity of atmospheric air. The *sulphuretted hydrogen gas* is at once identified by its action on paper previously dipped in a solution of a salt of lead: if present even in very small proportion (1–100,000th part), the moistened paper speedily acquires a brownish-black stain from the production of sulphide of lead. It must not be supposed that sulphuretted hydrogen, when it has proved fatal in a *diluted* form, can be detected in the lungs, stomach, or blood of a dead body. When the body is recently removed from a drain or sewer, the gas may be found pervading the whole of the tissues; but in other cases it will be as useless to look for it as for carbonic acid in poisoning by this gas. Noxious gases are not long retained by the tissues; a short exposure will suffice to remove all traces of them. The examination of the locality can alone throw a light upon the cause of death. The proportion of the gas found in an apartment will, however, rarely be a criterion of the actual quantity which has destroyed life. A person going into a room where the deceased bodies are lying, may notice only a disagreeable or stifling smell, but he may be able to

breathe for a longer or shorter period with the door or window open. It is not the respiration of a few minutes, but the breathing of the diluted noxious atmosphere for many hours, that really destroys life. The best method of detecting sulphuretted hydrogen when present in a dead body (not putrefied) is to place a slip of card glazed with lead, in the muscles or soft organs: it will sooner or later be tarnished and acquire a brown color, if the gas is present.

Sulphuretted hydrogen may be proved to exist by the lead-test in the vapor of *hydrosulphate of ammonia* when mixed with air; while the presence of ammonia in the compound, is indicated by its volatile alkaline reaction on test-paper—also by holding, in a vessel containing the vapor recently collected, a rod dipped in strong hydrochloric acid; the production of dense white fumes announces the formation of hydrochlorate of ammonia. The presence of this compound vapor in any mixture is at once indicated by introducing paper wetted with a solution of nitro-prusside of sodium. The hydrosulphate produces with it a rich crimson color: if sulphuretted hydrogen alone is present, the nitro-prusside paper undergoes no change. It is a fact which cannot be too universally known that a candle will readily burn in a mixture of either of these gases with air, which, if breathed, would suffice to destroy life. (“Ann. d’Hyg.,” 1829, vol. 2, p. 69.) The candle-test should be applied with caution in places where these effluvia are collected and confined in sewers or close cesspools. When sulphuretted hydrogen is diffused in a proportion of about 7 per cent. with air, it forms a dangerously explosive mixture.

It is worthy of remark that the air of a cesspool may be often breathed with safety until the workmen commence removing the soil, when a large quantity of mephitic vapor may suddenly escape, which will lead to the immediate suffocation of all present. Several persons have been killed by trusting to the previous burning of a candle, in ignorance of this fact. In descending into sewers in order to render assistance to those who are lifeless, the person should on these occasions, whether sulphuretted hydrogen or carbonic acid be the cause, make a moderate inspiration of pure air and hold his breath while in the noxious mixture. In an accident which occurred in Whitechapel, in August, 1857, three men died speedily from breathing the vapor of an old sewer, and two others nearly lost their lives in attempting to assist them. The best plan for getting rid of the gas is by a free exposure of the locality, or by exciting active combustion in it. According to Parent-Duchâtelet, men can work for a time in an atmosphere containing from 2 to 3 per cent. of sulphuretted hydrogen. The air of one of the principal sewers of Paris gave the following results, on analysis, in 100 parts: Oxygen, 13.79; nitrogen, 81.21; carbonic acid, 2.01; sulphuretted hydrogen, 2.99.

Another gaseous mixture in the form of deoxidized air, was found by Thénard in the sewers of Paris: it was composed, in 100 parts, of nitrogen 94, of oxygen 2, and of carbonic acid 4. Sometimes the carbonic acid is combined with ammonia, and then it may be regarded chiefly as a mixture of nitrogen holding diffused through it the vapor of carbonate of ammonia, which is sufficient to render it highly irritating to the mucous membrane of the eyes and nose. Its action on the human body when breathed, will be readily understood from its chemical composition.

In its operation it is essentially negative, and destroys life by cutting off the access of oxygen. The small proportion of carbonic acid or of carbonate of ammonia existing in it could not give rise to asphyxia which so rapidly followed its inhalation. The chances of recovery are much greater in persons who become asphyxiated from the inspiration of this compound than in those who are exposed to the influence of the preceding. Commonly the immediate removal to a current of pure air is sufficient to bring about a recovery. Should death take place, it will be found on inspection that the internal appearances are the same as those which are met with in death from suffocation.

Analysis.—This compound has no offensive smell; it extinguishes a lighted candle: the carbonic acid contained in it may be removed by caustic potash, and then it will be seen that the great bulk of the mixture is formed of nitrogen—a gas which, by its negative properties, cannot be easily confounded with any other. In a mixed atmosphere of carbonic acid and sulphuretted hydrogen, the two gases may be separated by agitating the mixture with a solution of acetate of lead, and treating the precipitate with acetic acid, which dissolves the carbonate, and leaves sulphide of lead.

EXHALATIONS FROM THE DEAD.

It may be proper in this place to make a few remarks on the alleged danger of the exhalations given off by dead bodies in a state of putrescence. Formerly, there existed a groundless fear relative to the examination of a putrefied dead body; and during the last century, on several important occasions, medical witnesses refused to examine the bodies of deceased persons, who were presumed to have been murdered, alleging that it was an occupation which might be attended with serious consequences to themselves. Orfila has collected many accounts of the fatal effects which are recorded to have followed the removal of the dead some time after interment. (*“Traité des Exhumations,”* vol. 1, pp. 2 *et seq.*) He allows, however, that the details of most of these cases are exaggerated, and attributes to other causes the effects which followed. Indeed, the observations of Thouret and Fourcroy prove that these dangers are restricted within a narrow compass, and that in general, with common precautions, dead bodies may be disinterred, and transported from one locality to another, without any risk to those engaged in carrying on the exhumations. About the latter part of the last century, from fifteen to twenty thousand bodies, in almost every stage of putrefaction, were removed from the Cimetière des Innocens in Paris; and the accidents that occurred during the operations, which lasted ten months, were, comparatively speaking, few. The workmen acknowledged to Fourcroy that it was only in removing the recently interred corpses, and those which were not far advanced in decomposition, that they incurred any danger. In these cases, the abdomen appeared to be much distended with gaseous matter; if ruptured, the rupture commonly took place about the navel, and there issued a bloody fetid liquid, accompanied by the evolution of a mephitic vapor—probably a mixture of carbonic acid and sulphuretted hydrogen. Those who breathed this vapor, as it escaped from the body,

fell instantly into a state of asphyxia and died ; while others, who were at a distance, and who consequently breathed it in a diluted state, were affected with nausea, giddiness, or fainting, lasting some hours, and followed by weakness and trembling of the limbs. Some years since, when it was the practice to bury the dead in the crowded churchyards of London, lives were frequently lost by reason of the noxious gases and effluvia which at once filled every grave as it was made. These gases were chiefly carbonic acid and sulphuretted hydrogen ; they have been already fully described. A grave twenty feet deep was usually dug between strata of exposed coffins, and this grave was kept open until it was filled with bodies. In September, 1838, two persons were killed by the effluvia which had collected in one of these deep graves kept open in Aldgate Churchyard. (See, in reference to this subject, Henke's "Zeitschrift," 1840, vol. 2, p. 446 ; "Ann. d'Hyg.," 1832, p. 216 ; 1840, p. 131 ; 1840, p. 28, 32.) With ordinary precautions, and the careful use of well-known deodorizers, the remains of the dead may be removed and transported to other localities without injury to the living. Within a few years, many bodies have been thus removed without ill effects, from London cemeteries, as that of St. Andrew's, Holborn, and Old St. Pancras. Some remarks on this subject, by M. Devergie, will be found in the "Ann. d'Hyg.," 1869, 2, 78.

In addition to these exhalations from the dead, there are other gases and vapors of a poisonous nature, which are for the most part artificial products. It is seldom that individuals are exposed to respire them in such quantity as to cause serious symptoms or to endanger life.

LIGHTNING. COLD. HEAT. STARVATION.

CHAPTER XLIII.

EFFECTS OF THE ELECTRIC FLUID.—POST-MORTEM APPEARANCES.—COLD AN OCCASIONAL CAUSE OF DEATH.—SYMPTOMS.—CIRCUMSTANCES WHICH ACCELERATE DEATH.—POST-MORTEM APPEARANCES.—EFFECT OF HEAT.—STARVATION A RARE CAUSE OF DEATH.—SYMPTOMS.—APPEARANCES AFTER DEATH.—LEGAL RELATIONS.

LIGHTNING.

DEATHS from lightning are more common than is generally supposed. Although they usually occur under circumstances in which the facts are known, yet cases may present themselves in which the marks of violence left upon the dead bodies may be suggestive of homicide. Few or no statistics of these deaths have been published in England ; but in France the facts collected by M. Boudin show the following results: In twenty-

eight years—from 1835 to 1863—2238 persons were killed by lightning. From 1854 to 1864 inclusive, 967 persons were killed, 698 being males and 269 females. In the year 1864 alone there were 87 killed, 61 males and 26 females. Of 34 persons killed by lightning in the open fields during the year 1853, 15 were struck while taking shelter under trees; and of 107 persons killed by lightning between 1841 and 1853, 21 are reported to have been killed under trees. Children appear to escape this mode of death more than adults. (“Chemical News,” 1865, July 7 and Dec. 8.) In the Registrar-General’s report, issued in July, 1878, and former reports, the number of deaths from lightning in England and Wales for nine years (1869–1878) were 182, of which 147 were males. These returns do not show the actual number of deaths. In Prussia registration is compulsory, and in that country during the same period 819 persons were reported to have been killed by lightning. (“Brit. Assoc. Report,” Aug. 1878.)

Cause of death.—The electric fluid appears to act fatally by producing a violent shock to the brain and nervous system. In general there is no sense of pain; the individual falls at once into a state of unconsciousness. In a case which did not prove fatal, the person, who was seen soon after the accident, was found laboring under the following symptoms: insensibility; deep, slow, and interrupted respiration; entire relaxation of the muscular system; the pulse soft and slow; the pupils dilated, but sensible to light. (“Med. Gaz.,” vol. 14, p. 654.) It will be seen that these are the usual symptoms of concussion of the brain. The effect of a slight shock is that of producing stunning; and when persons who have been severely struck recover, they suffer from noises in the ears, paralysis, and other symptoms of nervous disorder. (“Med. Times,” July 15, 1848.) Insanity has even been known to follow a stroke of lightning. (Conolly’s “Report of Hanwell,” 1839.) In one case the person remained delirious for three days, and when he recovered he had completely lost his memory. (“Lancet,” August 3, 1839, p. 582.) A boy, æt. 4, received a severe shock on the 11th May, was seized with tetanus on the 13th, and died in four hours. (“Med. Times and Gaz.,” May 26, 1855.) In another instance an old man who took shelter under a tree felt as if a vivid flash had struck him in the face: he did not fall, but he became almost blind. He suffered for some days from frontal headache, and loss of sight supervened. (“Med. Times and Gaz.,” July 24, 1858.) Under slight shocks the principal symptoms are headache and confusion of intellect, which soon disappear.

It may be observed of the effects of lightning, generally, that death is either immediate, or the individual recovers. A person may, however, linger, and die from the effects of severe lacerations or burns indirectly produced. In a case which occurred in July, 1838, death was thus caused indirectly by the effects of electricity. The following case of recovery illustrates further the action of the electric fluid: Three persons were struck by lightning at the same time. In one, a healthy man, æt. 26, the symptoms were severe. An hour and a half after the stroke he lay completely unconscious, as if in a fit of apoplexy; his pulse was below 60, full and hard; his respiration snoring, his pupils dilated and

insensible. There were frequent twitchings of the arms and hands; the thumbs were fixed and immovable, and the jaws firmly clenched. Severe spasms then came on, so that four men could scarcely hold him in his bed; and his body was drawn to the left side. When these symptoms had abated he was copiously bled; cold was applied to the head, a blister to the nape of the neck, and mustard poultices to the legs. Stimulating injections and opium were also administered: in the course of twenty-four hours consciousness slowly returned, and the man soon completely recovered. The only external injury discoverable was a red streak, as broad as a finger, which extended from the left temple over the neck and chest: this disappeared completely in a few days. ("Brit. and For. Med. Rev.," Oct. 1842.) These red streaks or marks sometimes assume a remarkable disposition over the skin. (See case by Dr. Horstmann, Casper's "Vierteljahrs.," April, 1863, p. 308.)

Dr. G. Wilks, of Ashford, has given a full report of a case in which a man was struck and severely injured by lightning but he recovered. One remarkable fact in the case was that the whole of his clothes were stripped from his body, and he was left nearly naked. ("Brit. Med. Jour.," Nov. 1879, p. 698.)

Appearances after death.—The suddenness of death is such that the body sometimes preserves the attitude in which it was struck ("Med. Times and Gaz.," Feb. 18, 1860, p. 167), and there may be no appearances, no physical changes in the body or dress, to indicate the mode of death. Five negroes were simultaneously prostrated by a single stroke of lightning. Three, including two children, were instantaneously killed. The only mark of injury found on one, an adult female, was a burnt spot, the size of a dollar, under the right axilla, and this woman's clothes were set on fire. ("Dub. Med. Press," May 14, 1845.) Persons involved in the same flash do not all suffer equally. A man, woman, and a boy were struck simultaneously in an open field. The man heard the thunder; he felt his hat thrust down upon his head, as if by violent pressure. The boy was confused and unsteady, but conscious. The woman was lying on the ground, speechless and moaning. She soon recovered. She had heard no thunder and saw no lightning. ("Brit. Med. Jour.," Jan. 1876.) Those who are severely struck do not hear the thunder. Generally speaking there are, externally, marks of contusion and laceration about the spot where the electric current has entered or passed out:—sometimes a severe lacerated wound has existed: on other occasions there has been no wound or laceration, but an extensive ecchymosis, which, according to Meyer, is most commonly found on the skin of the back. In one instance, which occurred in London, in May, 1839, there were no marks of external violence; and several similar cases are quoted from American journals in the "Medical Times" (May, 3, 1845, p. 82). The clothes are in almost all cases rent and torn, and partially singed, giving rise to a peculiar burnt odor,—sometimes even rolled up in shreds and carried to a distance. They are occasionally found partially burnt, but this is not a frequent occurrence. Metallic substances about the person present traces of fusion, and articles of steel have been observed to acquire magnetic polarity. Dr. West has informed me, that in a case to which he was called, in which a boy, æt. 18,

had been instantly struck dead by lightning, he observed that a knife in the pocket of the deceased had acquired strong magnetic polarity. The case further shows that which has frequently been noticed—namely, that while much violence has been done to the dress, the parts of the body covered by it have escaped injury. The deceased wore at the time of the accident a pair of strong leather boots: these were torn to shreds, probably owing to the presence of iron nails in the soles, but the feet of the deceased presented no mark of injury! An accident by lightning occurred in the presence of a friend of mine, by which a healthy man was instantaneously killed. A cap which the man wore, had a hole through it; his hair was singed, his shoes were burst open, and his trousers torn. The woodwork of the building, down which the electric fluid passed, was merely split and there was no mark of burning. I have examined, in several instances, the wood of trees which have been struck by the electric fluid: in each case it has presented only the appearance of rending by mechanical force, the inner bark being torn from the alburnum.

Wounds and burns are sometimes met with on the body. The wounds have commonly been lacerated punctures, like stabs produced by a blunt dagger. In the case of a person who was struck but not killed, a deep wound was produced in one thigh, almost laying bare the femoral artery. This person was struck, as many others have been, while in the act of opening an umbrella during a storm. Fractures of the bones have not been commonly observed: in a case mentioned by Pouillet, the skull was severely fractured and the bones were depressed. (“*Traité de Physique, Elect. Atmosph.*”)

In May, 1864, Dr. Mackintosh, of Littleport, was called to see three persons who had been struck by lightning about *twenty minutes* previously. They had taken shelter under a haystack, which had been set on fire by the same flash. 1. A boy, aged 10, was then able to walk, although unable to move his legs immediately after the occurrence. All that he remembered was—he saw the stack on fire and called to his father; he felt dizzy all over and unable to move. His hair and clothes were not singed, and the metallic buttons on his dress showed no signs of fusion. On removing his clothes a slight odor of singeing was perceptible. He complained of pain at the lower part of the abdomen. There were several red streaks, of about a finger's breadth, running obliquely downwards and inwards on either side of the chest to the middle line in front of the abdomen; they then descended over the pubes, and were lost in the perineum. It does not appear that there was any abrasion of the skin. This boy perfectly recovered; the red streaks disappeared gradually, and could hardly be traced four days after the injury. 2. Another boy, aged 11, lay prostrate and unconscious, with an expression of grim terror and suffering; he frothed at the mouth, moaned piteously, and flung his legs and arms about in all directions. The breathing was deep, slow, and laborious; the heart palpitating, pulse weak and very irregular; the pupils were dilated, and insensible to light. There were in this case several red streaks converging from the neck and shoulders to the middle of the chest-bone, and passing over the abdomen until they were lost on the pubes. There were similar streaks radiating

for a few inches from the tuber ischii on each hip in different directions, until they were lost in the skin. It appears that this boy was in a sitting posture when struck. The hair on the back of his head and neck was singed, and the peculiar odor of singeing was perceived, although his clothes showed no traces of burning, nor the metallic buttons of fusion. The boy became conscious in five hours, and rapidly recovered. The red streaks gradually disappeared, leaving marks of a scaly glistening white appearance, which ultimately left no trace of their existence.

3. A man, aged 46. Like the two others, he was in a sitting posture, and he appeared to have been killed on the spot; he had not moved hand or foot. The countenance was placid, and the pupils were widely dilated. The electric fluid had produced a large *lacerated wound* of the scalp, at the junction of the occipital with the parietal bones, but without producing any fracture. The electric fluid appeared to have passed down each side of the head, between the soft parts and the cranium. On the left side it had passed downwards in front to the left ear, and terminated on the side of the neck, rupturing bloodvessels and muscles, and causing swelling of the parts with effusion of blood. It presented the appearance of an extensive bruise caused by mechanical violence. On the right side the current had passed down to the space above the collar bone, causing lividity and swelling of the right ear as well as of the adjacent skin; and it terminated in a dark-blue mangled patch of skin, in which there were several free communications with the surface. The hair on the back of the head was slightly singed, and that in front of the chest was singed quite close to the skin, but the hair which covered the wound in the scalp, where the current had entered, was uninjured. The clothes were neither torn nor burnt, and the metallic buttons were not fused. The clothes of all three were very wet. The hat was not examined. The left side-pocket of the trousers contained several lucifer matches and a tin tobacco-box, which were unaffected by the electric discharge. The right pocket contained a knife, which had acquired strong magnetic polarity. The body was placed in a warm room, and it is worthy of remark that cadaveric rigidity came on in fourteen hours after death. ("Lancet," July 30, 1864, p. 118.) It is to be regretted that no post-mortem examination was allowed. It is probable that the brain sustained severe injury, causing immediate death. These cases singularly present the effects of lightning in three degrees—the effect of a slight shock in No. 1, of a severe shock in No. 2, and of a fatal shock in No. 3. There was but little bodily injury in either case, and no appearance of burning. The marks on the skin in Nos. 1 and 2 could not have been mistaken for violence, but the wound to the scalp and the injuries to the neck in No. 3 might have been ascribed to the violence of another, had not the circumstances been fully known. The clothes probably escaped burning or tearing by reason of their being wet, and their readily conducting the electric fluid.

The *burns* occasionally found on the bodies of persons who have been struck by lightning have been hitherto ascribed to the ignition of the clothes. It appears, however, from the subjoined cases, that burns, even of a severe kind, may be the result of a direct agency of the electric fluid itself upon the body. The late Dr. Geoghegan met with the case

of a girl who had been struck by lightning; there was burning of the thigh and buttocks to the first and second degrees, but the clothes did not show any signs of combustion. On the 16th of July, 1852, a man, æt. 23, while engaged in milking a cow in a wooden shed, during a severe thunderstorm, suddenly observed a vivid flash of lightning, which killed the cow instantly, and inflicted serious injuries upon himself. He was seen sixteen hours after the accident, and a severe burn was found on his person, extending from the right hip to the shoulder, and covering a large portion of the front and side of the body. His mind was then wandering, and there were symptoms of inflammatory fever. The man was confined to his bed for seventeen days, at the end of which time the injuries had not perfectly healed. On examining his dress, the right sleeve of his shirt was found burnt to shreds, but there was no material burning of any other part of the dress. The case is singular, inasmuch as it shows that the dress may be burnt without the surface of the body being simultaneously injured; and further, that a burn may be produced on the body, although the clothes covering the part may have escaped combustion.

Mr. Fleming has described the cases of eight persons who were struck by lightning, and on the bodies of some of these there were marks of severe burns. The dresses were in parts much singed. These cases show, in a remarkable manner, the intense heat evolved in the instantaneous passage of the electric fluid through the clothes and body. The persons struck, were benumbed or paralyzed in various degrees, but all ultimately recovered; the burns were so severe that some months elapsed before they were entirely healed. ("Glasgow Med. Journal," October, 1859, p. 257.) A man was struck by lightning in July, 1861. Externally there was a burn upon the nape of the neck, where the metallic watchgaurd rested; and from the point where the current of electricity left the chain, the skin was blistered in a straight line down to the feet, scorching the hair of the pubes in its course. The man's intellect was confused, and his general condition was that of collapse. With the aid of stimulants he became sufficiently restored to communicate his feelings. There was paralysis of the legs, with loss of sensibility (anæsthesia), and retention of urine. He was deaf, and complained of a noise in his ears like thunder; he had some difficulty in articulating, and pain in swallowing with a peculiar metallic taste in his mouth. The anesthesia passed away in half an hour, but he did not completely recover the use of his limbs for four days; the bladder was paralyzed for twenty-four hours, and only relieved by the use of a catheter; the urine was high-colored, and contained an abundance of phosphates. The bowels were confined. All these symptoms gradually disappeared, excepting slight deafness, and the man was discharged coalescent.

The following complete account of external and internal appearances found in the body of a healthy middle-aged laborer, who was killed by a stroke of lightning, has been published by Dr. Schaffer: The man was working in the fields with several other laborers, just after a thunderstorm had passed over and had apparently subsided. He was endeavoring to kindle a light with a flint and steel, when the lightning struck him. For a moment after the shock he stood still, and then his

body fell heavily to the ground lifeless. The electric fluid had entered at the upper part of his forehead, perforating and tearing his hat at that part: it seemed then to have become divided into two currents, which passed down the sides of the body along the lower limbs and out at the feet. On the upper part of the forehead was found a soft swelling, of a dark-blue color, and about the size of the palm of a hand: the hair which covered it was uninjured. From this spot two dark-red streaks proceeded in different directions. One of these passed to the left, running over the temple in front of the left ear, down the neck to the surface of the chest, over which it passed between the left nipple and the armpit; and so made its way over the body to the left inguinal region, where it formed a large, irregular, scorched-looking (brandige) patch on the skin. From this point the dark-red streak again continued its downward course, passing over the great trochanter, then along the outer surface of the left leg to the back of the foot, where it terminated in several small dark-blue spots. The other streak, which proceeded from the ecchymosed swelling on the forehead, passed directly to the right ear, which was considerably swollen and of a dark-blue color; from the ear it ran downwards and backwards along the neck, crossed the right border of the scapula, and eventually reached the right groin, where a scorched patch of skin, similar to that in the left groin, was found. From this part the discolored streak continued down the outer side of the right leg, to its termination on the back of the foot, just on the left side. It is remarkable that, although the hair on the forehead, as well as that which occurred in any part of the track taken by the electric current down to the groin, was not burnt, yet at the groin itself, and at every part hence to the foot over which the electric stream had passed, the hairs were completely burnt. The cause of the skin and hair in the groins being burnt is probably to be referred to the buckles of a belt which the man wore round his abdomen at the time of the accident: the belt was completely destroyed. Nothing further worthy of notice was observed on the exterior of the body, with the exception of the face being very red. The swelling of the head was found to be due to the presence of a large quantity of extravasated blood. The bone beneath was not injured. About four ounces of blood had been effused in other parts of the scalp corresponding to the swollen discolored patches outside. The vessels of the cerebral membranes were greatly congested, and the brain itself contained much blood, especially observed in the choroid plexuses. A large quantity of reddish mucus was found in the larynx, windpipe, and air-tubes. The lungs were loaded with dark blood; there was a great deficiency of blood in the cavities of the heart and in the large vessels. The bloodvessels of the stomach and intestines were more than usually congested. The right lobe of the liver was of a dark-red color, and loaded with blood, especially the part which corresponded to the burnt patch of skin at the lower part of the abdomen. The spleen also was large, and filled with blood. Much blood was found accumulated in the substance of the muscles of the abdomen, at those parts which lay beneath the burnt surfaces outside. ("Oesterreich. Med. Wochenschrift," 6th June, 1846.) It was formerly supposed that the blood was never found coagulated in persons killed by lightning, and that the body did not become rigid after

death. Experience has shown, however, that these statements are not in accordance with observed facts.

Ecchymoses resembling those produced by mechanical violence and of great extent are sometimes met with. A short, muscular man was killed by lightning. There was a strong smell of burning about the body. The hair was singed considerably at the back of the head, at the nape of the neck, and slightly above the forehead, at each corner of which there was a dark ecchymosis. The scalp was greatly ecchymosed at the top and at the back of the head. There was a large ecchymosis at the nape of the neck, and from this a livid band half an inch broad, curved round the right side of the neck, and terminated in a large ecchymosis at the sternal end of the right clavicle. The left forearm was scorched in front, and along the centre of the scorched surface ran a dark line about three or four lines broad. There was a slight ecchymosis on the right thigh and on the right side of the scrotum. About half-way down the right leg was an extensive scorch encircling the leg, and a line of about three-quarters of an inch in breadth, ran down the inner side of the leg to the sole. The soles of both feet were extensively blistered, and the cuticle charred. The clothing corresponding to the injured parts was extensively scorched, and large holes were burnt in the soles of the socks. The boots were scorched inside, but not injured outside, although there were iron nails in the soles. Excepting the nails of the boots, there was no metal about the body. The pupils were widely dilated. Cadaveric rigidity was unusually marked, requiring great force to overcome it. The inner surface of the scalp was ecchymosed. The brain appeared bloodless and soft, and there was but little fluid in the ventricles. The veins and sinuses of the base were filled with dark fluid blood. The heart was flabby; the right ventricle contained a small quantity of dark fluid blood; the great veins were distended with very dark blood, everywhere perfectly fluid. There was no coagulum or clot in any part, and the blood showed no tendency to coagulate after its escape. The lungs were very soft and much congested posteriorly. ("Med. Times and Gaz.," Oct. 14, 1865, p. 418.)

The external injuries in these cases resemble those caused by violence, but the peculiar form, extent, and direction of the ecchymoses, as well as the presence of marks of burning, either on the clothes or the body, were sufficient to distinguish them as injuries produced by the electric fluid.

Legal relations.—Rare as the combination of circumstances must be in which a medico-legal question can arise in reference to the action of the electric fluid on the body, a case was tried in France, in October, 1845, in which medical evidence respecting the characters of wounds caused by electricity was of considerable importance. In August of that year some buildings were destroyed at Malaunay near Rouen, as it was alleged on the one side, by a thunderstorm, on the other, by a whirlwind; and as the parties were insured against lightning, they brought an action for recovering the amount insured. The evidence in favor of the accident having been due to electricity consisted, first in the alleged carbonized appearance of the leaves of some trees and shrubs growing near; and secondly, in the characters of the wounds on the bodies of

several persons who were injured at the time of the occurrence. M. Lesauvage stated at the trial that there was an appearance of dark stains over the bodies, and that those who survived, suffered from torpor, pains in the limbs, and a partial paralysis of motion. He observed, also, that decomposition took place very speedily in the bodies of those who were killed. In one instance the muscles were torn and lacerated, and some small arteries divided. This witness attributed most of the wounds to the effects of electricity. M. Funel deposed, that in each of the dead bodies which he had examined, the face and neck were bloated and discolored, as if death had taken place from asphyxia. It did not appear, however, that there were any circumstances decisively proving that the buildings had been destroyed by lightning. M. Pouillet gave an accurate description of the storm: he believed that although, as deposed to by some of the witnesses at the trial, it might have been attended with thunder and lightning, the buildings with the surrounding trees were really overthrown by the mere force of the wind, and not by the electric fluid. The description given bears out this view, but at the same time it is unusual that trees when struck, unless old or dry and withered, should present any marks of combustion about the leaves or trunk. (See "Comptes Rendus," Sept. 1845; also "Med. Gaz.," vol. 36, p. 1133.) The scientific evidence was of the most conflicting kind. The Royal Court of Rouen decided that the disaster was occasioned by the atmosphere: and, without entering into the various theories of storms, condemned the insurance companies to pay the amount claimed. ("Law Times," March 14, 1846, p. 490.)

COLD.

Cause of death.—The protracted exposure of the human body to a low temperature may destroy life; and although in this country cases but rarely occur in which cold alone operates fatally, it is not unusual during a severe winter, to hear of persons in a state of misery and destitution, being found dead in exposed situations. On these occasions we may reasonably suspect that the want of proper food and nourishment has accelerated death. It is, however, convenient to make a distinction between the effects of cold and of starvation on the system, as the symptoms preceding death, and the rapidity with which it takes place, are different in the two cases.

Symptoms.—A moderate degree of cold is well known to have an invigorating effect upon the body; but if the cold is severe, and the exposure to it long-continued, while the caloric function is not maintained by warmth of clothing or exercise, the skin becomes pale, and the muscles become gradually stiff and contract with difficulty, especially those of the face and extremities. Sensibility is lost, a state of torpor ensues, followed by profound sleep from which the person cannot be readily roused: in this state of lethargy the vital functions gradually cease, and the person finally perishes. Such are the general effects of intense cold upon the body: its influence on the nervous system is seen in the numbness, torpor, and sleepiness which have been described as consequences of a long exposure to severe cold. Giddiness, dimness of

sight, tetanus, and paralysis have in some cases preceded the fatal insensibility. It has been found that temperature materially affects the amount of oxygen taken by the blood. At a low temperature this fluid takes less oxygen; hence it becomes less oxygenated, and this state of the blood affects the condition of the brain and nervous system. ("Bernard," op. cit. p. 114.) It was observed during the retreat of the French from Moscow, that those who were most severely affected by cold often reeled about as if in a state of intoxication; they also complained of giddiness and indistinctness of vision, and sank under a feeling of lassitude into a state of lethargic stupor, from which it was found impossible to rouse them. Sometimes the nervous system was at once affected; tetanic convulsions, followed by rigidity of the whole of the voluntary muscles, seized the individual and he rapidly fell a victim. Symptoms indicative of a disturbance of the functions of the brain and nervous system have also been experienced by Arctic travellers during their residence within the Polar circle. The late researches of M. Pouchet on the effects of a freezing temperature on animals have led him to the conclusion that death is due to a physical change in the blood-globules, and not to any effect on the nervous system. The first phenomenon produced by cold is a contraction of the capillary vessels to such an extent that the blood-globules cannot enter them; these vessels, therefore, remain completely empty. The second phenomenon is an alteration of these globules, amounting to their complete disorganization. Under these circumstances an animal cannot be restored. ("Chemical News," Dec. 1, 1865, p. 263.) A human being may, however, perish from a degree of cold not sufficient to produce congelation.

Circumstances which accelerate death.—There are certain conditions which may accelerate death from cold. In all cases in which there is exhaustion of the nervous system, as in those who are worn out by disease or fatigue, in the aged and infirm, or, lastly, in persons who are addicted to the use of intoxicating liquors—the fatal effects of cold are more rapidly manifested than in others who are healthy and temperate. It has been uniformly remarked that whenever the nervous energy is impaired, either by intoxication or exhaustion from fatigue, a man dies quickly from cold. The exposure of drunken persons during a severe winter may therefore suffice to destroy life, although the cold might not be so intense as to affect others who were temperate. Casualties of this nature sometimes occur during the winter season in this metropolis; and a knowledge of the influence of intoxication in accelerating death under such circumstances, may occasionally serve to remove a doubt in the mind of a practitioner respecting the real cause. Infants, especially when newly born, easily perish from exposure to cold. Cold, when accompanied by rain and sleet, appears to have a more powerfully depressing influence than when the air is dry,—probably from the effects of evaporation. The following case related to Dr. Currie shows the fatal effects of exposure to cold winds accompanied with humidity: "Of several persons who clung to a wreck, two sat on the only part that was not submerged; of the others, all were constantly immersed in the sea, and most of them up to the shoulders. Three only perished, two of whom were generally out of the sea, but frequently overwhelmed by the

surge, and at other times exposed to heavy showers of sleet and snow, and to a high and piercing wind. Of these two, one died after four hours' exposure; the second died three hours later, although a strong healthy adult, and inured to cold and hardship: the third that perished was a weakly man. The remaining eleven, who had been more or less completely submerged, were taken from the wreck the next day, after twenty-three hours' exposure, and they recovered. The person among the whole who seemed to have suffered least was a negro: of the other survivors, several were by no means strong men, and most of them had been inured to the warm climate of Carolina." The fatal action of extreme cold on animals has been lately examined by M. Crecchio. ("Ann. d'Hyg.," 1868, 1, p. 436.)

Appearances after death.—Opportunities rarely occur of examining bodies when death results purely from exposure to cold. The skin is commonly pallid, and the viscera of the chest and abdomen as well as the brain are congested with blood. Dr. Kellie, of Leith, found in two cases which he examined a redness of the small intestines from the congestion of the capillary vessels, and a great effusion into the ventricles of the brain. A sufficient number of cases have not yet been inspected, to enable us to determine how far these two last-mentioned appearances are to be regarded as consequences of death from cold; but all observers have found a general congestion of the bloodvessels and viscera. In consequence of the great congestion uniformly met with in the vessels and sinuses of the brain, some pathologists have regarded death from cold as resulting from an attack of apoplexy; but the symptoms which precede death do not bear out this view. Effusions of blood have not yet been observed, and a mere fulness of the cerebral vessels after death is not in itself sufficient to justify this opinion. It will be observed that, on the whole, these appearances are remarkably similar to those which are found in death from severe burns or scalds. In a case which occurred to Dr. Hilty, of Werdenberg, a man, æt. 57, in a state of intoxication, died from exposure to cold during a severe winter's night. A minute description of the appearances is given, but the principal were, great congestion of blood in all the cavities of the heart and the large vessels, the blood fluid and of a dark crimson color, a congested state of all the internal organs, especially of the liver and kidneys, numerous spots or patches of redness on the skin (frosterythema) and the bladder distended with urine. (Casper's "Vierteljahrsschrift," 1865, 2, 140.) Thus then a medical jurist will perceive, that in order to come to a decision whether, on the discovery of a dead body, death has taken place from cold or not, is a task of some difficulty. The season of the year,—the place and circumstances under which the body of the deceased is found,—together with the absence of all other possible causes of death (such as from violent injuries or internal disease), form the only basis for a medical opinion. Death from cold is not to be determined except by negative or presumptive evidence; for there is no organic change, either externally or internally, sufficiently characteristic of it to enable a medical man to give a positive opinion on the subject.

HEAT.

Intense heat.—Heat-apoplexy.—The effect of an intensely heated atmosphere in causing death has been but little studied. Some years since I was consulted in one case in which the captain of a steamvessel was charged with manslaughter, for causing a man to be lashed within a short distance of the stoke-hole of the furnace. The man died in a few hours, apparently from the effects of this exposure. The engine-rooms of steamers in the tropics have been observed to have a temperature as high as 140° ; and engineers after a time become habituated to this excessive heat, without appearing to suffer materially in health. In certain manufactures the body appears to acquire a power, by habit, of resisting these high temperatures—still it has been proved that many suffer severely. In a Report on the Employment of Children (1865), it is stated that in a glass-manufactory a thermometer held close to a boy's head stood at 130° , and as the Inspector stood near to observe the instrument, his hat actually melted out of shape. Another boy had his hair singed by the heat, and said that his clothes were sometimes singed too; while a third worked in a temperature of no less than 150° . Amid this tremendous heat they carry on work which requires their constant attention: they are incessantly in motion. In the Turkish bath higher temperatures than this have been noted, but there is reason to believe that serious symptoms have been occasionally produced in persons unaccustomed to them, and that in one or two cases death has resulted. All sudden changes from a low to a high temperature are liable to cause death in aged persons, or in those who are suffering from organic diseases. In attempting to breathe air heated to temperatures varying from 180° to 200° , there is a sense of suffocation with a feeling of dizziness and other symptoms indicative of an effect on the brain: the circulation is enormously quickened.

In July, 1861, an inquest was held in London on the body of a stoker of an Aberdeen steamship. He had been by trade a grocer, and was not accustomed to excessive heat. While occupied before the engine-furnace he was observed to fall suddenly on the floor in a state of insensibility; when carried on deck it was found that he was dead. All that was discovered on a post-mortem examination, was an effusion of serum into the ventricles of the brain; death had been caused by sudden apoplexy. In some cases a person may sink from exhaustion as a result of long exposure. Intense heat appears generally to operate by inducing congestion of the brain (heat-apoplexy). It has now become one of the recognized causes of death in this country in the Registrar-General's reports. In 1870, 112 deaths from sunstroke were registered in England; and from the returns for 1871, it appears that throughout England and Wales, 66 persons died of sunstroke in that year. In some cases a person may sink and die suddenly from exhaustion, or symptoms of cerebral disturbance may continue for some time, and the case ultimately prove fatal.

Death from sunstroke, when this is not immediately fatal, is preceded by some well-marked symptoms, such as weakness, giddiness, headache, disturbed vision, flushing of the face, followed by oppression, and diffi-

culty of breathing, and in some cases stupor passing into profound coma. The skin is dry and hot, and the heat of the body is much greater than natural. ("Ann. d'Hyg.," 1867, 1, 423.) In one case, observed by Dr. Sieveking, the patient, a boy æt. 13, remained in a state of semi-consciousness for four days, and then had a cataleptic seizure. ("Lancet," 1870, 2, 184.) Dr. Passauer has fully considered this subject in reference to armies in Horn's "Vierteljahrsschrift," 1867, 1, 185. The symptoms in cases of sunstroke have not been always accurately recorded. In one instance a medical man, who suffered from an attack while on a voyage in the tropics, was able to note and describe his symptoms from the commencement of the attack up to the eighth day, when he recovered. (See "Lancet," 1872, 1, 464; also, 2, 128.)

[Dr. H. C. Wood (Boyleston Prize Essay, Phila., 1872) considers that intense heat of skin is characteristic of true sunstroke; the temperature reaching, in some instances, to 110°, or even 113° F. In all autopsies made by him, the heart was firmly contracted, especially the left ventricle. He ascribes the flaccidity of the heart noticed by others, to the fact that the examination was not made for many hours after death, during which time putrefaction had set in. Dr. Wood found that congestion of the brain or effusion into the ventricles was not of frequent occurrence; nor did he observe any change in the blood, microscopically.—R.]

. STARVATION.

A rare cause of death.—Death from the mere privation of food is a rare event, although, if we were to form an opinion from the verdicts of coroners' juries, its occurrence would not appear to be uncommon in this and other large cities. In one of the Annual Registration Returns it is stated that 130 persons had died from starvation. Such cases must, however, be received with some distrust, as care is rarely taken to ascertain precisely how far bodily disease may have been concerned in the fatal result. Still it cannot be denied that starvation should be classed among the forms of violent death, being sometimes the result of criminal neglect or inattention in the treatment of children, lunatics, or of infirm and decrepit persons, and thus constituting homicide; or at other times, although rarely, arising from an obstinate determination to commit suicide in those from whom all other means of self-destruction are cut off.

Acute starvation.—Symptoms.—The symptoms which attend on the privation of food, or the supply of improper food, have been variously described. Referring to cases which occurred during the Irish famine of 1847, Dr. Donovan states that the persons who suffered, described the pain of hunger as at first very acute, but said that after twenty-four hours had been passed without food, the pain subsided, and was succeeded by a feeling of weakness and sinking, experienced principally in the region of the stomach; accompanied with insatiable thirst, a strong desire for cold water, and a distressing feeling of coldness over the entire surface of the body. In a short time the face and limbs became frightfully emaciated; the eyes acquired a peculiar stare; the skin exhaled an offensive smell, and was covered with a brownish filthy-looking coating, almost as indelible as varnish. This he was at first inclined to regard as en-

crusted filth, but further experience convinced him that it was a morbid secretion poured out from the exhalants on the surface of the body. The sufferer tottered in walking like a drunken man; his voice was weak, like that of a person affected with cholera; he whined like a child, and burst into tears on the slightest occasion. In respect to the mental faculties, their prostration kept pace with the general wreck of bodily power; in many there was a state of imbecility, in some almost complete idiocy; but in no instance was there delirium or mania, which has been described as a symptom of protracted abstinence among shipwrecked mariners. ("Dub. Med. Press," Feb. 1848, p. 67.)

In a case which fell under the notice of Dr. Sloan, a healthy man, æt. 65, was by an accident shut up in a coal mine for twenty-three days without food. When found he was conscious, and he recognized and named his deliverers. He was so weak that he could scarcely raise his hand to his mouth, and so much emaciated as to excite the surprise of his fellow-workmen by the extreme lightness of his body. Under careful treatment he so far recovered as to give an account of his feelings. For the first two days, hunger was his most urgent symptom. This passed off, and he then began to suffer from severe thirst, which he allayed by drinking some foul water. After *ten days* he became so weak that he was unable to move from the spot where he had lain down. He slept but little, and not soundly—never entirely losing the consciousness of his situation. His bowels acted only once, but he passed urine freely. The matter brought from his bowels by injections, was dark colored like meconium, and very fetid. He died on the third day after his removal, in spite of every effort to save him, and on the day of his death he was in the following state: his features were sharp and pale, his eyes sunk; the skin of the abdomen seemed to touch the backbone, which could be distinctly felt through it; his body presented more emaciation than Dr. Sloan had ever seen produced by disease; he had altogether a dried appearance, very much like that of natural mummies found in catacombs; his pulse was gone; his voice was in a whisper, like the *vox cholericæ*; there was uneasiness, increased by pressure, in the region of the stomach; his intellect was sound, and remained so until death. ("Med. Gaz.," vol. 17, p. 265.) This case confirms the observation of Dr. Donovan, that delirium is not a necessary attendant on protracted abstinence; and it proves incontestably that a person may die from the effects of abstinence or starvation, in spite of the best-directed efforts for recovery. Mr. Thornhill reports, in the same journal, the cases of eight men and a boy who were shut in a coal mine for eight days without food ("Med. Gaz.," vol. 17, p. 390); but the symptoms here noted were rather those of hunger than of long abstinence. They all suffered from excessive thirst; they were all troubled with ocular illusions, showing cerebral excitement. The occurrence of ocular spectra, and other symptoms indicative of a depressed state of the nervous system, have also been noticed by Casper. ("Handbuch der Ger. Med.," 1857, vol 1, p. 374.)

Under art. *Abstinence*, "Cyc. Pr. Med.," Dr. Marshall Hall and Dr. Latham record their experience of the effects produced by the privation of food. In advanced cases they found among the symptoms headache,

sented a livid appearance. He left the New York Hospital perfectly recovered on the 21st October, 1878.

Accidents to miners throw some light upon the power of endurance in the absence of food. In March, 1869, ten men and three boys were shut up in a coal mine in Staffordshire, and remained for *eight* days without food and light. They were all saved excepting one, who died frantic. In April, 1877, several men and a boy, who met with a similar accident in South Wales, were rescued in an exhausted state also on the eighth day. These cases show that an adult can exist without food for a period of eight days, and by due precaution ultimately recover. Casper believes that a period of from twelve to fourteen days is the limit for the survival of a strong healthy man entirely deprived of food. (Op. cit. 1, p. 369.) Casper's opinion receives some support from the case of a gentleman, æt. 26, reported by Mr. Headland to the Medical Society. ("Lancet," 1845, vol. 1, p. 681.) The patient had been advised to abstain from food and to take only water. For eleven days he acted on this advice, and tasted no kind of food with the exception of a teaspoonful of beef tea on the tenth day. He died on the twelfth day, having had for a few days a discharge of blood from the bowels.

On the other hand, there are instances of persons surviving for shorter periods, and ultimately recovering. Two men, one æt. 22, the other æt. 32, working in a well at Auquettierville, in November, 1879, at a depth of 100 feet, were suddenly shut in by a fall of earth. They were thus confined in an excavated space or chamber, about 13 feet by 9. Here they remained five days without food, although efforts were immediately made to save them. When rescued, they had still a certain amount of strength. They had suffered much from cold, but were gradually restored by judicious feeding. (Journal de Havre, 1879.)

The mode in which death takes place was accurately observed in the case of the Welsh fasting girl (p. 539). During the last hour she spoke nothing; she was too weak and too far gone. She was not sensible, but she appeared to be in a stupor like a dying person. In the case of *Harriet Staunton* death took place under similar circumstances (p. 536.)

Chronic starvation.—When the person survives for some weeks, and the food supplied is insufficient in quantity or of bad quality, other symptoms show themselves. Among these there is pain in the region of the stomach, a suppression of the feces, or, if discharged, they are in small quantity, dry, and dark-colored; the urine is scanty, high-colored, and turbid; the intellect is dull. The person may be exhausted, and remain without motion in one position, or be seized with a furious delirium, which may drive him to acts of violence. In the last stage the body is reduced to an extreme state of emaciation, and before death it evolves an offensive odor, like that of incipient putrefaction. The excretions have also a putrescent odor. The surface of the skin may be covered with spots (petechiæ), and the person finally dies, in some cases slightly convulsed. M. Chossat found, in his experiments on animals, that in some instances the animal died after having had successive attacks of convulsions. (Beck's "Med. Jur.," vol. 2, p. 80.)

Appearances after death.—There are but few details of the appearances presented by the bodies of those who have died from starvation, and the cases themselves are too rare to enable us to decide with certainty upon the accuracy of the reports which have hitherto appeared on the subject. The body is extremely shrunk and emaciated, and remarkable for its lightness. The skin is dry, shrivelled, and free from fat. The muscles are soft, deprived of fat, and much reduced in size. The stomach and intestines are usually found collapsed, contracted and empty,—the mucous membrane being thinned, and sometimes ulcerated. The liver, lungs, heart, kidneys, and the great vessels connected with these organs, are shrunk, collapsed, and destitute of blood; the heart and kidneys free from any surrounding fat—the gall-bladder distended with bile—the omentum shrunk and destitute of fat. In Dr. Sloan's case (*supra*) the body was observed to be extremely emaciated; the intestines were collapsed, the stomach was distended with air, and slightly reddened at its greater extremity. The omentum had almost disappeared; it was entirely destitute of fat. The liver was small, and the gall-bladder distended with bile. The other viscera were in their normal state. ("Med. Gaz.," vol. 17, p. 389.) Mr. Tomkins, of Yeovil, inspected the body of a man who died from starvation in February, 1838. The face was much shrunk and emaciated; the eyes were open, and presented a fiery-red appearance, as intense as in a case of acute ophthalmia during life. This red appearance has also been met with by Dr. Donovan in death from exposure to cold. "Dublin Med. Press," Feb. 2, 1848, p. 66.) The skin was tough, and there was scarcely any cellular membrane to be seen. The tongue, lips, and throat were dry and rough. A peculiar odor was exhaled from the body. The lungs were shrunk and contracted; the investing membrane was slightly inflamed. The stomach and intestines were empty, but quite healthy; the gall-bladder was nearly full of bile, and the surrounding parts were much tinged by this liquid. The urinary bladder was empty and contracted. ("Lancet," March, 1838.)

In some cases inspected during the Irish famine, Dr. Donovan states that the appearances which he witnessed were extreme emaciation, total absorption of the fatty matter on the surface of the body, total disappearance of the omentum, and a peculiarly thin condition of the small intestines, which in such cases were so transparent that, if the deceased had taken any food immediately before death, the contents could be seen through the coats of the bowel: on one occasion (at an inquest) he was able to recognize a portion of raw green cabbage in the duodenum of a man who had died from starvation. This thin condition of the coats of the intestines he looks upon as the strongest proof of death from (chronic) starvation. The gall-bladder was usually full, and the parts in the vicinity of it were much tinged by the cadaveric exudation of bile; the urinary bladder was generally contracted and empty, and the heart pale, soft, and flabby; there was no abnormal appearance in the brain or lungs. Dr. Martin assigns as a condition of the intestines diagnostic of starvation, that they are not only contracted, but shrunk and diminished in size, shortened in length as well as in calibre, and like a mere cord, as if the canal was obliterated. ("Med. Times and Gazette,"

March 30, 1861.) He met with this state in three cases ; once in starvation from want of food, and twice from total obstruction to its ingestion. Mr. Fletcher found the following appearances in the cases of two children, named *Aspinall*, who died from starvation—the elder aged one year and ten month, the younger four months. In the body of the elder there was extreme emaciation, without the slightest trace of disease of any of the viscera. Some dirty creamy fluid and four cherry-stones were found in the small intestines, but no distinctly fecal matter, a few grains of which, however, were found in the large intestines ; scarcely a trace of fat was visible. In the infant the same appearances were presented, although the emaciation had not proceeded to the same extent. The evidence produced on the trial proved that the mother had spent in drink the money given to her for household expenses, and that the children's food and clothing were neglected. The prisoners were tried for wilful murder, in accordance with the verdict of the coroner's jury. The judge ruled that the wife was in law the husband's servant, and if it were proved that he had supplied her with sufficient money, he must be acquitted ; if he had not, the wife must be acquitted. The jury acquitted the man, and brought in a verdict of manslaughter against the woman, who was sentenced to two years' imprisonment. ("Proceedings of Liverpool Medical Society," 1855–56.) In some of these alleged deaths by starvation, ulceration of the bowels is met with. This has been considered to arise from want of food ; but Dr. Donovan did not meet with it in the bodies of those who died of lingering or *chronic* starvation. ("Dublin Med. Press," Feb. 2, 1848, p. 66 ; also "Lancet," 1845, vol. 1, p. 681 ; 1849, vol. 1, p. 180 ; "Dublin Jour. Med. Science," vol. 3, p. 273.)

Dr. Copland describes among the appearances in the cases which he quotes, shrinking of the viscera, with increased vascularity of the brain and its membranes, with sometimes a limpid serous effusion between them. According to Dr. Osborne ("Dub. Jour.," 1839, vol. 15, p. 423), in cases which prove fatal from long abstinence, chronic inflammation of the stomach is one of the appearances met with. He says that those who die of starvation usually die with the mucous membrane of the stomach and bowels in a state of inflammation, and generally of ulceration. Hence it may be presumed that long fasting is injurious by inducing a state of irritability, causing the membrane to pass very readily into an inflammatory condition. A congested state of the stomach is, therefore, consistent with death from starvation.

Death from starvation or disease.—The post-mortem appearances, in order to throw a light upon the cause of death, should be accompanied with an otherwise healthy state of the body ; since, as it is well known, some of them may be produced by organic disease, and death may really be due to disease, and not to the privation of food. It will not be always easy to say whether the emaciation depends on disease or want of food, unless we are put in possession of a complete history of the case. On this account, in all charges of homicidal starvation, the defence generally turns upon the coexistence of disease in the body, and the sufficiency of this to account for death. As in most cases of death from protracted abstinence or privation of food, disease is likely to be set up, or if already

existing, to be aggravated by the want of proper nourishment, so it follows that in the bodies of persons who have died of starvation, traces of disease are generally found. In many of the recorded cases where disease existed, there has been no motive for disputing the cause of death, but on a charge of murder it is different. The cause of death may here be contested, and the case often admits of a strong defence. Adverse medical opinions will be given, and that conflict of evidence excited which often leads the authorities to ignore medical opinions altogether, and ultimately to decide cases by the facts elicited from non-professional witnesses, or by evidence from circumstances.

The Staunton case.—In no instance probably has this conflict of medical opinion been more strikingly shown than in what has been called the *Penge case*. (*Reg. v. Staunton*, Central Criminal Court, Sept. 1877.) The details of this case, and the medical opinion in reference to it, would fill a volume. The deceased, *Harriet Staunton*, had been kept in close confinement by the accused, four in number, and while in an almost moribund state, she had been suddenly removed by them to Penge, where she died, in a state of complete exhaustion, on the day following her removal. She was seen a few hours before her death by a medical man: she was then insensible, and in a state of complete collapse.

As the only persons about the deceased were the four accused and a servant girl, a relative of two of the prisoners, it was difficult to procure any trustworthy account of the symptoms preceding her removal and death. Such as they were, they substantially corroborated the conclusions drawn from a post-mortem examination of the body. The body was examined under an order of the coroner by Drs. Wilkinson and Bright, gentlemen of many years' standing in the profession, and by four surgeons. The appearances which they found were—the body greatly emaciated, skin parchment-like, dry and shrivelled, the muscles shrunk and entirely destitute of fat, the breasts almost imperceptible, the body covered with vermin. The entire weight was only seventy-four pounds, while in a healthy adult of the same age, it would be about one hundred and twenty pounds.

Internally: The stomach was small and so much thinned that the undigested food in it was distinctly visible through its coats. The intestines were pale, shrunk, and empty; they contained no food or fecal matter. When held up to the light, the wasting of the coats was well marked. The omentum was scarcely visible and quite destitute of fat, of which there was indeed a total absence in every part of the body. The organs of the chest and abdomen were shrunk, and smaller than usual. They were generally in a healthy condition. The only appearances of disease in the body were, 1. A slight tubercular deposit at the apex of the left lung. 2. A congested appearance of the cardiac extremity of the stomach, as well as of the duodenum. 3. There were two small patches of miliary tubercular deposit (*recent*) upon the arachnoid membrane on the upper surface of the left hemisphere of the brain. There was no deposit on the pia mater or on the base of the brain, and the arachnoid and pia mater were not adherent. There was no trace of meningitis, *i. e.*, inflammation of the membranes of the brain, either simple or tubercular. There was no effusion, softening, or disease of the brain.

From these appearances the medical gentlemen who examined the body drew two conclusions: 1. That there was no disease in the body sufficient to cause death, or to account for the extreme emaciation and exhaustion. 2. Considering that the appearances included all those which the best authorities assigned to death by starvation, it was their unanimous opinion that the cause of death in deceased, Harriet Staunton, was starvation and neglect, understanding by this an insufficient supply of proper food. The general evidence given at the trial appeared to satisfy the jury that there had been on the part of the accused intentional and deliberate neglect, and they returned a verdict of wilful murder against them.

For the defence, it was urged that the emaciation and other symptoms of starvation were due to disease—*i. e.*, to tubercular meningitis, and not to the privation of food, or the supply of insufficient food. If there were any truth in this theory, it followed that a grave mistake had been made in charging the accused with any crime. This defence was set up by three medical men who had not had an opportunity of seeing the body, or even of consulting with those who had made the inspection. They based their opinions on inferences which, in the judgment of the physicians and surgeons who had had full opportunity of examining the body, had no foundation in fact.

In accordance with public opinion, the capital sentence was commuted to penal servitude for life against three of the accused, while the fourth, Alice Rhodes, against whom the evidence of complicity and motive was weak, was discharged. The severe sentence thus passed upon the three principal criminals, showed that the authorities rejected this theory of death from natural causes.

Looking at all the medical facts of this remarkable case, there appears to me to be no reason to doubt that the deceased died from starvation, as the result of an insufficient supply of food. There was no proof whatever that the diseased appearances met with in the body had reached a stage sufficient to account for death, irrespective of starvation and neglect. No medical man had been called in to see the deceased during her long confinement. Her mother and all her relatives had been studiously prevented from visiting her. She was, in fact, for many weeks completely isolated from the world by the accused persons; and within the last twenty-four hours of her life, while in an exhausted and prostrate condition, she was hurriedly removed in an open vehicle and by rail a distance of more than twenty miles!

The only motive which could be suggested for this violent proceeding, was that the accused persons might thus be enabled, as death was imminent, to procure a certificate of death from a medical man not acquainted with the facts. They succeeded in procuring a certificate of death from apoplexy; but the medical gentleman who signed it had so much doubt, on hearing something of the previous history of the case, that he gave information to the coroner. But for this, the crime would probably have escaped detection and exposure.

It has been justly complained that on this occasion an undue importance was attached by the witnesses for the defence to the presence of a miliary tubercular deposit, about half an inch in diameter, on the arach-

noid membrane of the brain. The witnesses for the prosecution who saw it, agreed that it was recent, and quite insufficient to account for the extreme emaciation or death of the woman. One witness for the defence so far agreed with them as to say that he had never known such an amount of emaciation as was here described, to take place from such a cause within so short a time.

In all cases of death from alleged starvation, but especially in those where a charge of murder is raised, a medical man or expert is bound to give full effect to the presence of disease, its extent and its adequacy to cause appearances, such as are found on the body; but he must not invent facts and then theorize upon them, or take the facts observed by others and pervert them from their true meaning. All the medical witnesses for the prosecution agreed that there was no meningitis (inflammation of the membranes of the brain), nor any of the products of inflammation. As this statement was made by them upon oath from actual observation, any expert subsequently dealing with the case, was bound to accept and act upon it, or to reject the evidence altogether. In place of this, however, and in the absence of any inspection of the brain, they affirmed that meningitis was present, and that the woman died of it in a tubercular form! In a summary of the case in its pathological aspects by Professor Virchow, of Berlin ("Med. Examiner," Nov. 1877, p. 882), he states that he should not consider himself justified in regarding a deposit of tubercle, such as that described as of fatal significance, at least in a case (like this) where such deposit had its seat upon the convex surface of the left cerebral hemisphere. The jury at the trial, and the authorities to whom an appeal was subsequently made, rejected this theory of the cause of death. Had it prevailed, three notorious criminals would have been set free. If this mode of dealing with medical evidence and medical facts were generally followed, it would be scarcely possible to obtain a conviction in any case of actual homicidal starvation.

A non-professional critic truly observes of the Staunton case, that some medical men fastened upon the absence or deficiency of medical evidence in the case, as if it were conclusively proved that there was no other evidence—no evidence of deliberate maltreatment and deprivation of food. They entirely ignored the fact that a person laboring under phthisis, or even tubercular meningitis, may have death accelerated by the privation of food and maltreatment.

Voluntary starvation. Pretended fasting.—There are a few cases recorded in which persons have voluntarily abstained from food, liquid or solid, for the purpose of self-destruction. Suicide, as a result of perfect abstinence, is, however, exceedingly rare: the person cannot resist the intolerable thirst, or the desire for food, when placed within his reach. It has been sometimes observed among the insane. As it requires a period of about *ten days* for the destruction of life under these circumstances, *i. e.*, in the *acute* form of starvation, the resolution to abstain can be rarely maintained, and for the purpose of self-destruction starvation would never be resorted to, except when all other means of destroying life were removed.

[Perhaps the most remarkable case of voluntary fasting on record is

that of the now famous Dr. Tanner, aged 49 years, who completed the unprecedented period of *forty days*' entire abstinence from food, in New York, on Aug. 7, 1880. If we can believe credible witnesses, this man absolutely partook of nothing, during the period above mentioned, except a few ounces of water daily! His loss of weight, at the end of forty days, was thirty-six pounds. He weighed at the commencement 187½ pounds. The fluctuations in his pulse, temperature, and respiration were unimportant. This case is certainly quite unique, and its phenomena do not seem explicable on acknowledged physiological laws. Dr. Tanner alleges that on a former occasion he has fasted forty-two days; and he offers to repeat his experiment for a proper consideration. One of the most curious circumstances attending this feat is the perfect impunity with which he devoured all sorts of food immediately on ending his fast.—R.]

Pretended fasting has been a subject of imposture at various times. The case of *Ann Moore*, of Tetbury, is noticed by most medical jurists, as showing how easily the public—even the educated public—may be deceived, and how lucrative such an imposition, when it has once taken hold of the public mind, may become. According to her account, she began to abstain from food in March, 1807, and continued fasting for *six years*. It was then discovered, by close watching, that her daughter secretly gave her food and drink. It is stated, however, that during the last watch she had no food of any kind for a period of nine days and nine nights. ("Beck. Med. Jur.," 1, 58.) An imposture of this kind can only be detected by the most minute observation. The case of *Sarah Jacobs*, the *Welsh Fasting Girl*, December, 1869, shows that a watch too strictly kept may have the imposture revealed by the actual death of the person. This girl, æt. 13, is stated to have voluntarily abstained from any kind of food for a period of *two years*. She had kept her bed during that time—lying in it decorated as a bride, visited by hundreds of persons—in fact, she was thus publicly exhibited by her parents as a girl of miraculous powers. Her lips were moistened with water once a fortnight, but, according to the parents, no food was taken. Four professional nurses from Guy's Hospital were set to watch the girl, and the result was, that after passing through the usual stages of actual starvation she died on the ninth day! She refused to take food at any time, and voluntarily accepted a lingering death rather than reveal the exposure. Her parents and those around her allowed her to die! An inquest was held, and a post-mortem examination gave the following appearances: The body was plump and well-formed; the membranes of the brain were much injected, the brain itself was healthy and of proper consistency. There was a layer of fat from half an inch to an inch thick beneath the skin of the chest and abdomen. The contents of the chest were healthy. The stomach contained three teaspoonfuls of a semi-gelatinous substance of the consistency of syrup, having a slight acid *reaction*. The small intestines were empty, and presented no attenuation or thinning of the coats. In the colon and rectum there was half a pound of solid excrement in a hard state, which might have been there, according to the witness, a fortnight or longer. The liver was healthy, the gall-bladder

greatly distended with bile; the kidneys and spleen were healthy, and the urinary bladder was empty.

The medical evidence was to the effect that the child had died from exhaustion as the result of starvation; and the jury returned a verdict of death from starvation from the criminal neglect of the parents to administer food. They were tried on the charge of manslaughter at the Carmarthen Summer Assizes, 1870. (*Reg. v. Jacobs and wife.*) An attempt was made in the defence to refer death to shock, and not to the want of food. The medical facts relied upon in support of this theory were the presence of fat in the body, and the absence of any thinning of the coats of the intestines; but, as Dr. Fowler very properly pointed out ("Lancet," 1870, 2, p. 150), these conditions are only likely to be met with after long or chronic fasting, where the person has survived many weeks on insufficient or unnutritious food. In the case of this girl, the only proved abstinence from food was during the last eight days of her life, and this period of time would not suffice for the entire removal of the fat and the thinning of the coats of the intestines. The prisoners were convicted of causing the death of their child by criminal negligence. The father was sentenced to twelve months' imprisonment, and the mother to six months'. ("Lancet," 1872, 2, 132.)

The desire of a section of the public to know whether a human being could live two years without food has thus been gratified at the cost of life! Any one acquainted with the rudiments of physiology would know that the application of the tests of watching, if really efficient, could only end in death. A writer justly remarks, in reference to this case of lamentable credulity: "It is not science, but superstition, even to inquire into the possibility of any human being living a conscious life without food. The very profession to do so is either disease, fanaticism, or imposture, and should be treated as such."

PREGNANCY.

CHAPTER XLIV.

SIGNS OF PREGNANCY.—SUPPRESSION OF THE MENSES.—QUICKENING.—SOUNDS OF THE FŒTAL HEART.—FEIGNED PREGNANCY.—CONCEALED PREGNANCY.—PREGNANCY IN THE DEAD.—IMPREGNATION IN A STATE OF UNCONSCIOUSNESS.—LEGAL RELATIONS.

SIGNS OF PREGNANCY.

Suppression of the menses.—It is well known that in the greater number of healthy women, so soon as conception has taken place, this secretion is arrested. But there are certain abnormal conditions which must

not be overlooked. There are some cases recorded which show that women in whom the menses have never appeared may become pregnant. This, however, is allowed by all accoucheurs to be rare; and when it occurs, which we may readily learn from the account of the woman, it will be necessary to search for other signs in order to determine the fact of pregnancy. Irregularity as to the period at which the function takes place is common among females. This irregularity may depend upon the age of the person, or upon disease, either of which causes it will not be difficult to recognize. The continuance of the menses after conception may make a pregnancy appear short. A case is reported in which a woman was married in the summer of 1856, and the menses continued after as before marriage. In October, 1857, they ceased for the first time, and in the following December the woman was delivered of a full-grown child; as the abdomen was not much enlarged, she thought that she was only two months pregnant. ("Med. Times and Gaz.," April 30, 1859.)

There are numerous disorders of the uterus under which, irrespective of pregnancy, the menses may become suppressed. The continuance of the menstrual discharge, when once set up, is not a necessary condition for impregnation. The late Dr. Murphy has reported the case of a woman who for sixteen years went on bearing children, eight in number, without having had during that period any appearance of the menses. Dr. Reid, who quotes this case, mentions five instances that fell within his own knowledge in which females became pregnant notwithstanding a long previous cessation of the discharge. ("Lancet," September 10, 1853, p. 236.) The absence of the menses as a consequence of pregnancy is generally indicated by the good health which a female enjoys; and although disease may coincide with pregnancy, yet a careful practitioner will be able to estimate from the general symptoms the probable cause to which the suppression is due. On the other hand, a discharge perfectly analogous to the menstrual sometimes manifests itself, not merely for several periods in a pregnant woman, but during the whole course of pregnancy. (Dr. Murphy's "Obstetric Report," 1844, p. 9; also Henke's "Zeitschrift der S. A.," 1844, p. 265.) (See "Ann. d'Hyg.," 1873, 2, p. 140.) Mr. Whitehead has collected seven well-marked instances of menstruation during pregnancy. ("On Abortion," p. 218.) These facts show that we should be cautious in forming an opinion; we must not assert that, because a discharge continues, pregnancy cannot possibly exist, or because there is no discharge, a female must be pregnant. The retention of the menses within the uterus from any cause, may produce enlargement of the abdomen, and give rise to some of the external symptoms of pregnancy.

Feigned menstruation.—The menses may be either suppressed or retained; but if there be any strong motive for the concealment of her condition, a woman may feign menstruation. Dr. Montgomery detected a case of this kind, by the examination of the areolæ of the breasts. The woman had stained her linen with blood in order to make it appear that the menses continued, but she subsequently admitted that this was an imposition. It has been stated that there are differences between

menstrual and ordinary blood, but there are no certain chemical means of distinguishing them.

Prominence of the abdomen.—A gradual and progressive enlargement of the abdomen is a well-marked character of pregnancy: the skin becomes stretched, and the navel almost obliterated. This enlargement in general begins to be obvious about the third month, although there are some women of peculiar structure in whom the enlargement may not become perceptible until the fifth or sixth month, or even later: still it may be detected on examination. In fact, this sign can never be absent in pregnancy, although it may not be so apparent in some women as it is in others. The objection which exists to it is, that numerous morbid causes may give rise to prominence of the abdomen. This is undoubtedly the fact, as we have occasion to witness in the various kinds of dropsy, or in suppressed and retained menses—diseases which, in several instances, have been mistaken for pregnancy by eminent practitioners. On the other hand, instances are not wanting, in which, owing to the persistence of menstruation and the absence of quickening, the gravid uterus has been actually tapped by mistake for an ovarian tumor; the operation being speedily followed by the birth of a full-grown child! (Whitehead “On Abortion,” p. 186); but the history of a case will in general enable a practitioner to form a correct opinion. (“Ann. d’Hyg.,” 1873, 2, pp. 142 and 144.)

[In the Court of Oyer and Terminer of Cumberland County, Pennsylvania, August, 1859, in the case of Commonwealth v. McManus, the defendant was indicted for infanticide and for concealment of the death of a bastard child. The evidence on the part of the commonwealth was, that the prisoner had walked to the office of a physician residing some considerable distance from her residence, and that he, after an examination, declared that she was far gone in pregnancy; so far, indeed, that he had distinctly felt the sutures in the head of the child! A few days afterwards another physician was called in by defendant’s mother. He declared that she was with child, and would very soon be confined; whereupon the mother indignantly ordered him from the house. Subsequently, on the same day, an old woman, a neighbor, called at the request of the mother. She found the prisoner and her mother in a room together. The prisoner, who was seated on a bucket apparently undergoing the pains of labor, seemed to pull from herself something which she squeezed violently. The witness heard the falling of a body into the bucket, but saw nothing. This occurred on Friday. On the Monday following, the prisoner went in a wagon to a house some miles distant, carrying with her a covered basket. This she placed in the closet of the room where she was to sleep. While it was there, the woman who owned the house having occasion to go into the room, perceived a most disagreeable and offensive odor, which, upon investigation, she discovered proceeded from the prisoner’s basket in the closet. In the evening the prisoner took her basket, for the purpose, as she said, of going to the house of an acquaintance, who lived beyond the creek near by; when she returned the basket was empty, and the odor had disappeared. A few days after, the body of a new-born infant was found in the creek several miles below where the prisoner had crossed.

This, it was alleged by the commonwealth, was the prisoner's child, which had been strangled by her, and subsequently thrown into the water.

It was proved, however, that the prisoner never had given birth to a child, or even been pregnant; but that for years she had suffered from suppression of the menses. The physician who originally attended her proved that he had recommended her to sit over a bucket of steaming water as a means of obtaining relief. What the old woman had heard fall into the bucket was a clot of blood, loosened by the effects of hot vapor. The odor in the basket came from a bottle containing a quack lotion of herbs, with which she was in the habit of washing herself, and which had been broken when she jumped from the wagon upon reaching her destination. The defendant was acquitted.—P.]

A change in the breasts.—These organs in a pregnant woman are full and prominent, and the areolæ around the nipples undergo changes of color which Dr. Montgomery and others regard as highly characteristic of the pregnant state. A mere fulness or pain in the breasts, and even in some rare instances the secretion of milk, may arise from other causes than pregnancy. Severe uterine or ovarian irritation may cause the breasts to become painful and swollen. The fulness of the breasts from pregnancy is not commonly observable until about the second or third month. A more or less transparent fluid is secreted by the gland-tissue of the breast, and can be expressed from the nipples. This secretion of milk may occur in a non-pregnant female as a result of uterine or ovarian disease. Such cases, however, are not very common; but after a woman has once secreted milk, the secretion may be reproduced in the breasts by very slight causes quite independently of pregnancy.

The *areola* is generally observed during pregnancy to become considerably darker in color and larger in diameter. The skin of which the areola is formed is soft, moist, and slightly tumid. The little glandular follicles about it are prominent, and often bedewed with a secretion: the change of *color* has been chiefly attended to. The areolæ are commonly well marked in from the second to the fourth month of pregnancy—the intensity of color being the last condition of the areola to appear. The prominence of the glandular follicles does not always exist in pregnancy, and the areola may become large and dark-colored from other causes; consequently these signs are only to be looked upon as corroborative. In females of dark complexion, the areolæ are naturally dark irrespective of pregnancy; and in some advanced cases these changes in the areolæ are entirely absent. (“Edin. Month. Jour.,” March, 1848, p. 693.) Dr. Montgomery has described as a sign of pregnancy the existence of a *brown line* extending from the pubes to the navel, especially in women of dark complexion, and a dark-colored but not raised areola of about a quarter of an inch in breadth around the navel; but this also may be produced by uterine or ovarian disease.

Quickening.—The signs above given are applicable to the early as well as to the late stages of utero-gestation; but that which we have here to consider is one which is rarely manifested until about the fourth or fifth month. Quickening is the name applied to peculiar sensations experienced by a woman about this stage of pregnancy. The symptoms

are popularly ascribed to the first perception of the movements of the foetus, which occur when the uterus begins to rise out of the pelvis ; and to these movements, as well as probably to a change of position in the uterus, the sensation is perhaps really due. The movements of the foetus are perceptible to the mother before they are made evident by an external examination. The term is derived from the old Saxon word "quick," signifying living ; as, at the time when medical science was in its infancy, it was considered that the foetus only received vitality when the mother experienced the sensation of its motion ! On the occurrence of quickening there is generally a great disturbance of the system, indicated by syncope, nausea, and other distressing symptoms. After a short time the woman recovers ; and if sickness had hitherto attended the pregnant state, it has been frequently observed to disappear when the period of quickening has passed.

No evidence but that of the woman herself can satisfactorily establish the fact of quickening, and this it is necessary to bear in mind ; since, in some cases in which pregnancy is an object of medico-legal importance, proof of quickening may be demanded by law. Dr. Reid remarks ("Lancet," September 10, 1853, p. 237), with respect to this sign, that few women can tell the exact day on which they first feel it ; and a large proportion cannot place it within a range of fourteen days, which is of little assistance in the calculation of the probable date of delivery. Women who profess to be most exact in noting the period of quickening differ from each other as to the time. There is much self-deception as to this symptom. The discovery of the movements of a child by an examiner is really a proof that the usual period of quickening is past, but their non-discovery at the time of examination is no proof whatever that the woman has not quickened ; since the movements are by no means constant, and may be accidentally suspended even at several successive examinations. Besides, cases every now and then occur in which well-formed healthy women do not experience the sensation of quickening during the whole course of pregnancy ; and, what is of more importance, the movements of the child may be at no time perceptible to the examiner. The uncertainty of quickening as a sign of pregnancy is too well known to require more than adverting to. Women have been known to mistake other sensations for it, and in the end it has been proved that they were not pregnant. A woman may declare that she has felt quickening when she has not : and unless the movements of the child are perceived by the examiner at the time, how is he to confirm or disprove her statement ? Quickening, then (so far as it concerns the statement of the woman), cannot be relied on as a proof of pregnancy ; but if the movements of a child can be felt by the examiner through the abdomen, this is clear evidence not only of the woman being pregnant, but of her having passed the period of quickening. According to the general experience of accoucheurs, quickening takes place from the tenth to the twenty-fifth week of pregnancy ; but the greater number of instances occur between the *twelfth* and *sixteenth* week, or between the fourteenth and eighteenth week after the last menstruation.

From these observations, it will be seen that an examiner may sometimes detect the *movements of the child* about the third or fourth month,

at others not until the fifth or sixth, and in other instances not at all throughout pregnancy. Dr. Ahlfeld found that in forty-three cases in which the day of its occurrence was noted it ranged from 108 to 134 days—the average being 132.7 days (“Amer. Jour. Med. Sci.,” Oct. 1870, p. 567). Even in those cases in which the movements of the child have indisputably existed, they are not at all times to be perceived; hence several examinations should be resorted to before any opinion can be fairly expressed from their absence. The best mode of examining the abdomen for foetal movements is to allow the hand to remain at rest upon it. If the patient has quickened recently, the impulse is slight, and generally at only one spot, which, however, is seldom the same. Should she have advanced further, then the movements will be more rolling, and the parts of the child be detected at the same time. In making these examinations a diagnosis may be facilitated by previously immersing the hand in cold water and then suddenly applying it to the abdomen. When the movements of the child are distinctly perceived through the skin of the abdomen, they constitute a certain sign of pregnancy; but their non-discovery at a particular time is no proof that a female is not pregnant. The “jury of matrons” probably trust to this sign; hence their verdicts commonly turn out to be erroneous. There is another source of fallacy which may present itself when an artful woman is desirous of making it appear that she is pregnant—namely, that a woman may simulate the movements of a child by a peculiar action of the abdominal muscles. Medical practitioners of repute have been deceived for a time by this artifice, but this occurred before the discovery of chloroform or the stethoscope.

Sounds of the foetal heart.—Another sign is that which is derived from *auscultation*. By the application of the ear, or a stethoscope, to the abdomen, at or about the fifth month of pregnancy (rarely earlier), the pulsations of the foetal heart may be recognized and counted. These pulsations are not synchronous with those in the arteries of the mother: they are much more rapid, and thus it is impossible to mistake them. Their frequency, according to Dr. Hope, is in an inverse ratio to the stage of gestation, being 170 at the fifth and 120 at the ninth month. Sometimes, however, the foetal pulse may descend to 80 or even 60 beats in a minute. This sign, when present (like the foetal movements), not only establishes the fact of pregnancy beyond all dispute, but shows that the child is living. The sound of the foetal heart is, however, not always perceptible; when the child is dead, of course it will not be met with; but its absence is no proof of the death of the child, because the hearing of the pulsations by an examiner will depend very much upon the position of the child's body, the quantity of liquor amnii, the presence of disease, and other circumstances. Thus, the sounds may be distinctly heard at one time and not at another; they may be absent for a week or fortnight, and then will reappear; so that, although their presence affords the strongest affirmative evidence, their absence furnishes uncertain negative evidence; and several examinations should be made, in the latter case, before an opinion is formed. The earliest time at which the pulsations may be heard, has been stated to be about the fourth month, but they will be best heard after the sixth month. The reason why the sounds

of the foetal heart are not always perceived, is owing not only to changes in the position of the child, but to the vibrations having to traverse the liquor amnii and the soft layers of the skin of the abdomen. The presence of much fat in these layers intercepts them. The point where the sounds can be most readily perceived is in the centre of a line drawn from the navel to the anterior inferior spinous process of the ilium on either side—perhaps most commonly on the right. When clearly detected, they furnish an unequivocal sign of the pregnant state. Besides the sounds of the foetal heart, there are other sounds to which the name of "placental murmur" or *uterine sounds* has been given. These are heard from an earlier date, *i. e.*, at any time after the third month. As they may occur in connection with fibroid tumors of the uterus, they do not necessarily indicate pregnancy. (See a paper on this subject by Dr. Druitt, "*Med. Times and Gaz.*," Jan. 21, 1860.)

In reference to these signs of the pregnant state it may be observed, that if the motions of the child or sounds of the heart be perceptible, no other evidence of pregnancy need be sought for. The mere suppression of the menses, prominence of the abdomen, and fulness of the breasts cannot alone establish the fact; but unless the morbid causes of these abnormal states of the system be clearly and satisfactorily obvious to the examiner, it is a fair presumption from these symptoms that the woman is pregnant. In any case in which a doubt exists we should require sufficient time to form a correct opinion.

Changes in the mouth and neck of the uterus.—The signs hitherto mentioned are chiefly relied on in medical practice; but it must be remembered that no case can occur in civil or criminal jurisprudence, in which it will not be in the power of a medical witness to make an examination of the woman. He may then form a safe judgment from the changes which take place in the neck of the uterus, and from the sensation imparted to the finger by the presence of a rounded body (like the foetus) floating in a liquid, when an impulse is given to the uterus from below. Up to the fifth or sixth month of pregnancy, the neck of the uterus may be commonly felt projecting into the vagina; it is of its usual length, hard and firm. After that period, the uterus rises into the pelvis, and the neck is spread out, and is shorter and softer, the aperture increasing in size and becoming rounder. Towards the end of gestation, the neck of the uterus appears to be lost, becoming like a thin membrane, and sometimes no aperture can be felt.

A well-marked test of pregnancy is the motion perceptible to the finger on giving a sudden impulse to the child through the neck of the uterus. Capuron calls this the touchstone in the distinction of the pregnant state: without it, he considers a medical jurist may be easily deceived. To this passive motion of a child, the name of *ballottement* is given. It cannot be easily determined before the fifth or sixth month; but after the latter period, especially as pregnancy becomes advanced, it is always available. In the French schools, the method of applying the *toucher* and *ballottement* to pregnant females is systematically taught, and by a little practice it may be easily acquired. This motion to the child can also be given through the abdomen, by external *ballottement*, in two ways: either by the patient lying on her side, the hand placed on the most depend-

ing part of the uterus, or by placing the patient on her elbows and knees : the uterus will then fall forwards, the child also will fall in contact with the front wall of the uterus, and its presence thus be made more perceptible. This latter mode is best adapted for the early stages of pregnancy.

If we find amenorrhœa or suppressed menses, and a tumor distended to a size consistent with the duration of the amenorrhœa—if the tumor be more or less central, alternately relaxing and contracting, containing an irregularly shaped body, which is freely moved within, and also self-moving, we have clear indications of a living foetus : and if we add to these the foetal heart-sounds, with the other minor symptoms, we have a condition which, if clearly made out, must be considered complete proof of pregnancy. Of course we may have certainty with the foetal heart-sounds and movements if well marked ; and a strong suspicion from the other symptoms.

As most of these signs refer to an advanced stage, a witness may be asked, what are the unequivocal indications of pregnancy *before the fifth and sixth month* ? The answer to this question is of little moment to a medical jurist, since he is rarely required to give an opinion under these circumstances. In all *legal* cases, when pregnancy is alleged or suspected, it is the practice for a judge or magistrate, on a representation being made by a medical witness, to postpone the decision one, two, or three months, according to the time required for obtaining *certain evidence*. This evidence will consist in plainly distinguishing : 1. A rounded body floating freely in a tumor, which alternately relaxes and contracts ; 2. The movements of a foetus ; and 3. The sounds of the foetal heart. The most experienced men agree, that before the *sixth month* the changes in the neck and mouth of the uterus are of themselves too uncertain to enable an examiner to form a safe opinion : and, *à fortiori*, it is impossible to trust to external signs alone. Mr. Whitehead dissents from this view, and considers that a specular examination of the mouth of the uterus is not only more satisfactory than any other mode of exploration, but that it will enable a person to determine with certainty, the existence of pregnancy during its earlier stages—from a few days after conception to the middle or end of the fourth month, when auscultation first becomes available. In the *fourth week* the lips of the mouth of the uterus at the centre of their margins are permanently separated to the extent of one or two lines ; and the os tincæ (the aperture) itself, which was before a mere chink with parallel boundaries, forms an elliptical or sometimes rounded aperture, which is occupied by a deposit of transparent gelatinous mucus. At *six or eight* weeks it is decidedly oval or irregularly circular, with a puckered or indented boundary having a relaxed and lobulated character. The whole circumference of the neck is enlarged, and the commissures or angles of the mouth are obliterated. The mouth continues of its irregular form throughout the whole period of gestation ; but from the time of quickening to the end of the seventh month, the progressive changes are not so marked as to form a guide for determining the period of pregnancy. (“ On Abortion,” p. 204.) This condition of the mouth of the uterus must not be confounded with its

menstrual state in the early stages, nor with a diseased state in the latter stage of gestation.

[A bluish or dusky color of the vagina, produced by venous congestion, was originally declared by Jacquemin to be an almost certain sign of pregnancy in females who are not subject to hæmorrhoids. This statement has been confirmed by Kluge, Parent-Duchâtelet, Kilian, Wistrand, and Montgomery, the last of whom says, "In every instance, without a single exception, in which I have found this appearance distinctly marked, pregnancy coexisted." ("Sig. and Symp. of Preg.," 2d ed., p. 245.) It should, however, be remembered that pregnancy may exist, although this sign may not be visible. (Wharton & Stillé, "Med. Jurisp.," 1873, ii. p. 15.) The presence of *kietrin* in the urine is no longer regarded as affording *positive* proof of pregnancy.—R.]

Feigned pregnancy.—Pregnancy has been sometimes feigned or simulated for the purpose of extorting charity, of obtaining a settlement in a parish, or of compelling marriage; but it is scarcely necessary to observe that an impostor may be easily detected by a well-informed practitioner, since a woman always feigns an advanced stage of pregnancy. It is more easy to prove in most cases that a woman is not pregnant than that she is. ("Ann. d'Hyg.," 1873, 2, p. 145.) Although she may state that she has some of the symptoms depending upon pregnancy (and, unless she has already borne children, she will not be able to sustain a cross-examination even respecting these), yet it is not possible for her to simulate without detection, a distension of the abdomen or the state of the breasts. If she submits to an examination, the imposition must be detected; if she refuses, the inference will be that she is an impostor. Women have been known to possess the power of giving apparent prominence to the abdomen, and even of simulating the movements of a child by the aid of the abdominal muscles. By placing them under the influence of chloroform, the abdomen at once collapses, and the imposture is detected. These cases of spurious or feigned pregnancy are sometimes met with in hysteric females. (See case by Dr. Simpson, "Edin. Month. Journ.," 1854, 9, 473. See also "Lancet," April 14, 1855, p. 381; April 28, 1855, p. 429; and May 26, 1855, p. 533.) Pregnancy may be feigned by a woman in order to avoid being sent on a magistrate's order to a distant parish, or to escape the punishment of hard labor, to which she may have been sentenced. If in the latter case the slightest doubt should exist whether the woman is really pregnant or not, an affirmative opinion should be given, at least for a time, since great and even irreparable mischief might result by taking an opposite course.

In civil cases of feigned pregnancy, an examination should always be made before giving an opinion, or the reputation of a medical man may suffer by his forming a hasty conclusion on the subject from insufficient data. In this respect the case of *Devonald v. Hope* (Q. B., December, 1838) is of some interest. A medical man having given an opinion that a female patient was pregnant, subsequently brought an action against her for medical attendance. It turned out, however, that she was not pregnant, and that there were no satisfactory medical grounds upon which his opinion was based. The plaintiff complained of having been deceived by the defendant as to her condition; but it is obviously

in the power of any medical man to prevent such a deception being practised on him. An external examination only will not suffice either to affirm or negative the allegation of pregnancy, except when it is stated to be far advanced. For a singular case in which, on a charge of assault, evidence of this kind was tendered, see "Med. Gaz.," vol. 36, pp. 1083, 1169. (On the fallacy of the signs of pregnancy, and the simulation of this state, see a paper by M. Tardieu, "Ann. d'Hyg.," 1845, 2, 429; also, 1846, 1, 83; also, the same journal 1873, 2, p. 145.)

Concealed pregnancy.—By the law of Scotland, if a woman conceals her pregnancy during the whole period thereof, and if the child of which she was pregnant be found dead, or is amissing, she is guilty of an offence, and is liable to prosecution. Evidence is sometimes given as to outward appearances indicative of pregnancy; but the main proof of a woman having been pregnant, and that which is relied on for conviction, is clear and distinct evidence of the actual delivery of a child. This is generally furnished by medical witnesses. The Scotch law, by making the concealment of pregnancy under the circumstances above mentioned, an offence, proceeds on the principle that every pregnant woman is bound to make preparations for the safe delivery of a child; and it is, therefore, assumed that if a child be born clandestinely without preparation, and is found dead or is amissing, its death is owing to the want of such preparation.

Impregnation in a state of unconsciousness.—It was formerly a question whether a woman could become *pregnant* without her knowledge. This may undoubtedly happen, when intercourse has taken place during profound sleep (lethargy), or when a woman has been thrown into this state by narcotic drugs or vapors. But it is difficult to admit that any woman should remain pregnant up to the time of her delivery, without being conscious of her condition, if the intercourse took place during the waking state. A woman endowed with ordinary intellect could not avoid *suspecting* her condition after the fourth or fifth month; and this alone would be sufficient to induce her to seek advice whereby the fact would become known to her. When a woman is impregnated in a lethargic state, it is unlikely that she should go beyond the sixth month without being fully aware of her pregnancy; and if her motives were innocent, she would undoubtedly make some communication to her friends. Capuron mentions a case of this kind, in which the fact of pregnancy was first ascertained at the end of the fourth month, by the woman having complained to one of her sisters of a strange sensation which she experienced in the lower part of her abdomen. ("Méd. Lég. des Accouchemens," p. 86.) In a case related by the late Mr. Skey, a young woman who had had intercourse knowingly, was supposed not to have been aware of her pregnancy until the seventh month; but there is reason to believe that this woman was guilty of deception. ("Med. Gaz.," vol. 39, p. 212.) There are generally, in these cases, strong motives for falsehood; hence such stories require close investigation before they are allowed to influence the opinion of a practitioner. A case occurred in September, 1857, in which a woman, æt. 22, described as modest and decorous in her behavior, then advanced to the sixth month of pregnancy, asserted that she had not consciously had connection with any one, although she

specified a date at which she remembered she had lost her consciousness—at which date intercourse might have been had! On being questioned, she denied that she had had at any time any soreness or pain in her private parts. Although there may be unconscious intercourse followed by pregnancy, it is not probable that in the case of a virgin there should be such intercourse without the production of pain, soreness, or laceration; and these symptoms, if not perceived at the time, should be felt subsequently and create a suspicion, if not an actual knowledge, of what had happened. This rendered the account which the woman gave wholly improbable. The fact that she was able to fix a date for her unconsciousness, with an accuracy in accordance with her condition, was also a suspicious circumstance.

Unconscious pregnancy.—It is quite possible that women who are living in connubial intercourse may become pregnant without being conscious of it. Dr. Rüttel mentions the case of a woman, æt. 41, who had been married upwards of sixteen years, and who, while returning from a neighboring village, was suddenly delivered of her first child, when only a few days before she had been complaining that she was not likely to have any children. The child was born living and mature. (Henke, "Zeitschrift der S. A.," 1844, p. 264.) Mr. Long met with a case in which a married woman, æt. 24, subject to irregular menstruation, consulted him for an attack of spasms. On his arrival, he found that she had suddenly given birth to a seven months' child. Neither her husband nor herself had the slightest idea that she was pregnant. She had noticed that she had become somewhat stout, and that her breasts were more full than natural. She attributed her condition to improved health, and the cessation of the menstrual discharge was set down to some accidental cause. ("Med. Times and Gazette," June 13, 1857, p. 592. See, also, a case at full term by Dr. Tanner, "Obstet. Trans.," vol. 4, p. 113.) I am indebted to a late distinguished judge for the following fact in reference to unconscious pregnancy: A married lady, who had not had a child for a period of nineteen years, found herself, as she thought, getting unusually stout. She was moving about with her family to different places. At last her size alarmed her, and she thought she was suffering from dropsy; she consulted a physician, who informed her that she was in an advanced state of pregnancy. She treated this opinion with great contempt. In travelling with her daughter, they arrived at a miserable inn; on the night of their arrival, this lady was seized with the pains of labor, and was delivered of a child. She had made no preparation for the birth, and, up to the moment when she was seized with labor-pains, she had not, with all her former experience, the slightest idea that she was pregnant. (For other cases in which married women have had no consciousness of pregnancy, see "Lancet," June 16, 1860, p. 609, and June 30, 1860, p. 643.) Instances of this kind are important in reference to alleged unconscious delivery in women charged with infanticide. At the same time all cases in which there are motives for pleading unconscious intercourse or pregnancy require close examination; they will frequently be found to be quite unworthy of belief. This remark especially applies to unmarried women, who often consult a medical man on their condition with a full knowledge that they have

exposed themselves to the chances of pregnancy. Up to the time at which the foetal movements are perceptible, a woman may honestly attribute her condition to other causes. Dating from the middle period of pregnancy, however, she must be aware of her state, but she endeavors to dissemble this even to herself. ("Ann. d'Hyg.," 1873, 2, p. 148.)

Pregnancy in the dead.—There is no special case in law wherein the *fact of pregnancy* requires to be verified after the death of a woman: but an examination may be necessary in order to determine the identity of a body, or to rescue the reputation of the deceased from a charge of unchastity. The discovery of an embryo or foetus with its membranes in the uterus, would of course at once solve the question when the necessity for an examination occurred; and the practitioner will remember that, even supposing many years to have elapsed since interment, and the body to have been reduced to a skeleton, still if the foetus had reached the period at which ossification takes place, traces of its bones will be found amidst the bones of the woman. In examining the body of a woman long after death, for the purpose of determining whether she was or was not pregnant at the time of death, it may be proper to bear in mind that the unimpregnated uterus undergoes decomposition much more slowly than other soft organs. In the case of a woman who had been missing for a period of nine months—whose body was found in the soil of a privy, so decomposed that the bones separated from the soft parts—the uterus was of a reddish color, hard when felt, and its substance was firm when cut. The fact was of importance. It was alleged that the deceased was pregnant by a young man, and that in order to conceal her condition he had murdered her. From the state of the uterus, Casper was able to affirm that this organ was in its virgin condition, and that the deceased was not pregnant at the time of her death. On this representation the accused was liberated. ("Ger. Leich.-Oeffn.," vol. 1, p. 93.) In examining bodies many months after interment, and in one case upwards of a year, I have been surprised to find, that while other soft organs were decomposed, the uterus had scarcely undergone any change: its substance was still firm and hard.

It may happen that the appearances in the uterus are sufficient to create a strong suspicion that a woman has been pregnant, but the ovum, embryo, or foetus may have been expelled: in this case several medico-legal questions will arise in reference to delivery.

Legal relations.—There are two cases in English jurisprudence in which proof of the pregnancy of a woman may be required. It is impossible that a medical opinion can be given in either case until the woman has undergone examination. If she is acting *bonâ fide*, it is to her interest to submit to this, and the medical man incurs no responsibility. Assuming that an opinion is required on the pregnancy of a woman who refuses to be examined, a medical man would be acting illegally in compelling her to undergo an examination, and he might bring on himself a charge of indecent assault. It is only by the free consent of the woman that such an examination can be at any time made. (See "Infanticide.")

In the two cases in which opinions are usually required, a woman alleges that she is pregnant, but she would not be benefited by the alle-

gation until she had undergone an examination. One of them relates to the civil, and the other to the criminal law. 1. Under a writ *de ventre inspiciendo*. When a woman asserts that she is pregnant and is likely to give birth to a posthumous child, the heir-at-law to the estate may claim a right to have her statement verified and proof given that she is really pregnant. The object of this proceeding is to prevent the possibility of the heir being defeated of his rights, by the fraudulent substitution of the child of another person. Formerly, the proof of pregnancy in such cases was intrusted to matrons nominated by the sheriff, but now the matter is more considerably left to skilled medical practitioners. There will be no difficulty in such a case, provided the pregnancy is at all advanced. Examinations may be made at intervals, until the motions of a foetus are clearly perceived, with the other concomitant signs above described. An examination of this kind should be made completely. No woman should be able so to feign pregnancy as to deceive a skilled medical man. 2. The other case, referring to criminal law, is where a woman, after a capital conviction, pleads her pregnancy in bar of execution. If she is pregnant, the execution of the sentence is postponed until after her delivery. The strict letter of the law requires that married women taken from any who may be in court, should be impanelled to examine the convict and report on her condition. They are required to decide whether she has or has not passed the stage of quickening. It is however the practice with some learned judges to direct the examination to be made by a medical man, for the purpose of avoiding those mistakes into which a jury of ignorant matrons has frequently fallen.

In a recent case of conviction for murder (*Reg. v. Burns and Tracey*, Liverpool Winter Ass., 1880), the prisoner Tracey pleaded that she was quick with child. Chief Justice Coleridge accepted the plea without the jury of matrons, but, on the following day, he found himself compelled to resort to the ancient practice. A medical man was appointed to instruct the matrons, and, in fact, to advise them as to their verdict. The prisoner's statement was found to be correct, and she was respited.

These are, I believe, the only cases in which pregnancy has any direct relation to medical jurisprudence; and it is remarkable that, with respect to them, the law of England has expressly provided that they should be left to the decision of non-medical persons! The following conclusions may therefore be drawn: 1. That the cases in which the signs of pregnancy become a subject of *legal* inquiry in England are rare. 2. That there is no case, in English law, in which a medical man will not have an opportunity of performing an examination *per vaginam*: but this can only be made with the consent of the woman. 3. That a medical opinion is never required by English law-authorities, until the pregnancy is so far advanced as to render its detection *certain*. Hence, discussions concerning areolæ, the condition of the breasts, the presence of kiæstein in the urine, etc., are, in a practical point of view, unnecessary to a medical jurist. By these remarks I do not intend to undervalue the importance of an accurate knowledge of the signs of pregnancy to a medical practitioner. Cases which may never come before a court of law will be referred to him, and the serious moral injury which he may inflict on an

innocent woman by inaccuracy, should make him cautious in conducting an examination and in expressing his opinion. The medico-legal questions connected with the pregnant state have been comprehensively examined by M. Stolz. (See "Ann. d'Hyg.," 1873, 2, p. 137.)

DELIVERY.

CHAPTER XLV.

DELIVERY IN THE LIVING.—CONCEALED DELIVERY.—SIGNS OF ABORTION IN THE EARLY STAGES OF PREGNANCY.—SIGNS OF RECENT AND REMOTE DELIVERY.—FEIGNED DELIVERY.—DELIVERY IN A STATE OF UNCONSCIOUSNESS.—SIGNS OF DELIVERY IN THE DEAD.—TRUE AND FALSE CORPORA LUTEA.—CHARACTERS OF THE OVUM OR EMBRYO.—MOLES.—CONCEALMENT OF BIRTH.

DELIVERY is a subject which much more frequently requires medico-legal intervention than pregnancy. It will be sufficient to state that the concealment of birth, the crimes of abortion and infanticide, with questions relative to supposititious children, are closely dependent on the proof of parturition. This subject will admit of being considered under two heads: 1. As it relates to delivery in the *living*. 2. As it relates to delivery in the *dead*. In undertaking the investigation, we ought, if possible, to ascertain, either from the female herself or from those around her, whether there was reason to suspect that she was pregnant. If we can acquire any knowledge on this point it will materially facilitate our inquiry; but this is not always possible. It has generally happened, that previous pregnancy has been so concealed that few who saw the woman suspected her condition; then again, as the admission of her delivery may be the strongest proof of her criminality, she will perhaps resolutely deny it; and a medical practitioner has no right to extort this admission from her. From this it will be seen that a medical witness must often be prepared to prove the fact of delivery against the woman who is criminally charged.

Delivery in the living. Concealed delivery.—The signs of delivery in a *living* woman vary materially, according to the time at which this event has taken place. In common language, if the contents of the uterus are expelled before the sixth month, the woman is said to miscarry, or to have an abortion; if after the sixth month, she is said to have a premature labor. The law does not admit any such distinction; the expulsion of the ovum, foetus, or child by criminal violence, at any period of utero-gestation, is regarded as a miscarriage or abortion. It has been well observed that the signs of delivery are indistinct in proportion to

the immaturity of the ovum. Thus, when it takes place at the second or third month, there are scarcely proofs which can be derived from an examination of the woman. All the ordinary signs of delivery at the full period will be absent,—the development of the embryo not having been sufficient to cause any prominence in the abdomen, or to give rise to those changes in the system which take place previously to the birth of a mature child: *e. g.*, enlargement of the breasts and dilatation of the mouth of the uterus. Abortion at this period (the second or third month) is generally accompanied by loss of blood, which may manifest itself by its effects on the body. This, however, can only give rise to a suspicion. At a later period of gestation there may be a discharge resembling the lochia, and the mouth of the uterus may be found enlarged and soft; but from the small size of the fœtus, the outlet may present no positive evidence of delivery. The quantity of blood lost may be greater, and may have a more decided effect on the system. Of course, if the ovum, fœtus, or any of its membranes be found, then the presumption of abortion will be strongly supported: but women who designedly conceal their condition, will commonly take effectual means to prevent the examiner from obtaining evidence of this kind.

Signs of recent delivery in the living.—The woman is weak, the countenance pale, the eyes are surrounded by livid areolæ, and there is an appearance of general indisposition. Any severe illness may, however, give rise to similar symptoms. Their sudden occurrence from a state of previous good health, especially when pregnancy is known or suspected, will create a strong suspicion. The *breasts* are large and full, especially about the third or fourth day after delivery; the nipples are enlarged, and the areolæ around them present all the characters of advanced pregnancy. If the appearances described are not well marked at the first examination, they may be seen at a later period; and in a doubtful case, when the embryo or fœtus is not forthcoming, a second examination should be made before a final opinion is given.

1. The *skin* of the abdomen is relaxed, sometimes thrown into folds; the cuticle interrupted by light-colored broken streaks, passing especially from the groins and pubes towards the navel, which is more or less stretched and altered in appearance. Any disease which has caused enlargement of the abdomen may give rise to a similar appearance in the skin, so that when taken alone, much confidence cannot be placed in these lines or streaks as proofs of delivery. The round form of the enlarged and semi-contracted uterus may be felt at the lower part of the abdomen, generally lying towards one or the other side. The apparent size of this organ will depend upon the degree to which it has contracted, and therefore greatly upon the time at which an examination is made. Dr. Montgomery has pointed out the existence of a dark line extending from the pubes to the navel, with a dark areola around the latter, in cases of recent delivery; but he has found this line to exist independently of pregnancy and delivery—in one case in a girl aged 10, and in another instance in a lady laboring under an ovarian tumor.

2. The *organs of generation* will be found externally swollen, contused, or even lacerated, with clots of blood about them. The outlet is much dilated, the vagina relaxed, the mouth of the uterus considerably open,

and its margin completely relaxed. The neck of the uterus is shortened, and scarcely perceptible; and the body of this organ is from two to four times the size which it has in the unimpregnated state. It occasionally happens that the neck of the uterus is lacerated on one side during the passage of the head in primiparæ; should a laceration or a cicatrix be found, it will much assist in proving delivery.

3. *The presence of the lochia* (from *λοχος*, child-birth).—This is a discharge, at first of a sero-sanguineous liquid, but which afterwards appears as a brown or green-colored serum. It commences soon after delivery, and continues from a week to a fortnight, or even longer; it may be absent after the third day. The discharge has so peculiar an *odor*, that some have regarded this alone as furnishing strong evidence of recent delivery.

The signs which have been here enumerated are found only when no delay has taken place in making the examination, and the woman has been *recently* delivered. In some strong and vigorous women the body resumes its natural state within a few days, and the traces of parturition may have wholly disappeared, or have become so ambiguous as to furnish no satisfactory evidence. In others again, proofs of delivery will be obtainable for a fortnight or three weeks afterwards. In most cases, however, it is difficult, if not impossible, to say, after the lapse of *eight or ten days*, that delivery has certainly taken place, the signs having commonly by that time disappeared. In all cases the earlier the period at which an examination is made, the more satisfactory will be the evidence obtained. Dr. Montgomery once examined a woman *five days* after her delivery at the full time, and he was particularly struck with the degree to which the parts had become restored to their ordinary condition, especially the mouth and neck of the uterus, which hardly differed from their natural and unimpregnated form. (“Cyc. Pr. Med.,” loc. cit.) This inquiry becomes of considerable importance in a case of alleged child-murder. When the body of a child is not found until after two or three weeks from the time of its birth, and the suspected woman denies that she has been delivered of a child, she will probably not deny her pregnancy, but may assert that she has had an abortion at an early period. (See a case by Dr. Walther, of Labiau, in Casper’s “Vierteljahrsschrift,” Oct. 1863, p. 275.) In cases of abortion at an early period, the placenta is not always discharged at the time at which the embryo or fœtus is expelled from the uterus. (“Med. Times and Gaz.,” March 12, 1859.) A microscopical examination of the discharges might reveal placental or chorionic structures. In a case which occurred to Dr. Paxton, of Kilmarnock, all the usual signs of delivery were present in a woman æt. 20: she had evidently lost much blood, and was much reduced. From the state of the organs, Dr. Paxton considered that she had been delivered of a child within three days. There was no lochial discharge at the date of examination. The woman had previously denied her pregnancy when charged with concealment of it, but after the medical examination she altered her statement, and said that she had not only been pregnant, but was so at that time. On a farther examination, the uterus was found to contain a fœtus advanced to about the sixth month, and in three months more she was delivered of a child. What caused the appearances

of delivery, the condition of the breasts, &c.? Either she had shortly before been delivered of a child, or of a blighted ovum or foetus. Neither foetus nor placenta was ever seen or could be found, but the woman had had ample opportunity to dispose of them. This may have been a case of twin conception, or of superfœtation. It shows that in charges of concealment of pregnancy or delivery, it must not be inferred when the appearances of delivery clearly exist, that the uterus is empty. The organ should always be examined in order to determine whether it does not contain another foetus.

Signs of delivery at a remote period.—A question may arise whether it is in the power of a medical practitioner to determine the period at which delivery took place, i. e., how long a time has elapsed. This becomes necessary, when, in cases of concealed birth, abortion, or infanticide (some time after suspected parturition), a child is found, and it is required to determine whether the time which has elapsed since the birth of the child, either dead or living, corresponds with the supposed delivery of a suspected woman. An opinion may be given within eight or ten days after delivery, from the state of the breasts—of the discharges (lochia), and of the mouth of the uterus; but it becomes difficult after the sixth day; and when the tenth or twelfth day has passed it is still more difficult. After two or three months it may be regarded as impossible to assign the date of delivery with any degree of precision. (See Devergie, "*Méd. Lég.*," vol. 1, p. 446.)

In a case of pretended delivery, contested legitimacy, or disputed chastity, a medical jurist may be required to say whether a woman has, at any antecedent period of her life, been delivered of a child. This question, it must be remarked, can be raised only in respect to delivery at the full period, since there is no doubt that abortion in the early stages of pregnancy may take place, and leave no traces of such an event discoverable in after-life. Indeed, a few days or weeks are sometimes sufficient to obliterate all evidence of the fact. With respect to delivery at the full term, certain signs have been mentioned, which by some are considered indelible. These are: shining streaks on the skin of the abdomen, a brown mark reaching from the navel to the pubes, and the state of the mouth of the uterus, which is said never to close so effectually as in the virgin. In regard to the appearance of the skin of the abdomen, it may be remarked, that any morbid causes giving rise to a distension of the cavity—as ovarian enlargement or dropsy—will produce the same effect: so, also, to a certain extent, extreme emaciation from a state of obesity. (See "*Med. Times and Gaz.*," April 17, 1861, p. 450, on False Cencières.) Then, again, these marks on the skin are not always persistent throughout life. Besides, a woman, according to the statements of good observers, may be not only once, but repeatedly delivered, without having these marks produced. ("*Med. Times and Gaz.*," June 9, 1860, p. 583; also "*Ann. d'Hyg.*," 1873, 2, p. 139.)

With regard to the state of the mouth of the uterus it is liable to vary in different women, and to be affected by disease—so that a certain judgment cannot always be formed from its condition. In a woman who has not borne children the mouth of the uterus is in the form of a slit, the angles being bent down, and giving to it the appearance of the *os tinctæ*

(trench's mouth.) Mr. Whitehead has observed that, in a woman who has borne children, the mouth becomes elongated, and loses the slight bend at each of its extremities; the labia are thickened, and more nearly of equal size; the commissures are less clearly defined, and the whole of the neck is enlarged, and not so compact in texture. ("On Abortion," p. 195.) It must be remembered, however, that the condition of the mouth of the uterus, even in the virgin, varies at each menstrual period. Should there be congenital occlusion of the vagina, or the hymen be found imperforate, this will at once negative a previous delivery; but the latter condition will not negative a previous pregnancy, since a woman may have been impregnated, and have had an abortion at an early stage of pregnancy, without a necessary destruction of the hymen. This sort of negative evidence may, however, be sometimes of great value. There is a total want of good affirmative evidence of delivery at a remote period in the living, if we except that which is furnished by the presence of cicatrices in the vagina or of a cicatrix as a result of a lacerated perineum. It is rare, however, that any decision on this subject is required in medical jurisprudence. It might be demanded, either in a case of infanticide, when a woman was accused of having destroyed her alleged offspring some months or years before; or in a case of contested legitimacy, when a female is accused of having substituted a child of which she pretends she had been delivered at some remote period of time.

Feigned delivery.—Delivery has often been feigned by women for the purpose of extorting charity, compelling marriage, or disinheriting parties who have claims to an estate, and in other cases without any assignable motive. Of course, an imposition of this kind could not be sustained before a medical practitioner: and detection is rendered easy, because it is *recent*, and not *remote* delivery which is assumed. The latter would, if pretended, be generally cleared up by an examination, as well as by circumstantial evidence. (See case, "Med. Gaz.," vol. 19, p. 231; also another by Capuron, "Mél. Lég. des Accouchemens," p. 110.) [The case of Mrs. Cunningham, in New York, will suggest itself to the mind of the American reader.—P.]

Can a woman be delivered unconsciously?—Another important question relative to delivery in the living, is whether a woman can be delivered without being *conscious* of it. The signs of delivery may be discovered by a practitioner; the offspring may also be found. The woman may admit the fact of her delivery, but allege that she was totally unconscious of it. The only medico-legal case in which this plea is occasionally raised is in infanticide; and as the possibility of the occurrence may be questioned, the practitioner must be provided with a knowledge of those facts which medico-legal writers have accumulated respecting it. There is no doubt that a woman may be delivered unconsciously during profound sleep—while laboring under coma, apoplexy, asphyxia, syncope, or when suffering from the effects of narcotic poisoning—*e. g.*, the vapors of chloroform and ether, or intoxicating liquors. It is said, also, that delivery has taken place spontaneously while a woman was in the act of dying. This, however, has no bearing on the present question. It is in those cases where, after her recovery, a woman pleads unconsciousness of delivery that medical practitioners are chiefly consulted.

Besides the cases enumerated, hysteria when accompanied by loss of sense and motion, has been mentioned as a state in which parturition is liable to occur unconsciously. We need not be surprised at delivery taking place under these circumstances, when we consider that the contractile power of the uterus is altogether independent of volition: but, unless the morbid states already mentioned are accompanied by the most profound lethargy and entire loss of sensation, it can rarely happen that the contractions of this organ in its efforts to expel the child, should not at once rouse a woman into consciousness. We ought particularly to expect this in primiparæ, *i. e.*, in those who have never before borne children. At the same time it must be remembered that parturition in some women, especially when the pelvis is wide and the child small, may take place with such rapidity and ease as scarcely to be accompanied with pain.

It has been observed that, when a woman has frequently borne children, delivery sometimes takes place without effort, and without any consciousness on her part. On other occasions a woman may be in a kind of torpor or stupor, or suffer from eclampsia (puerperal convulsions), and have no recollection of her delivery. The following case is possible: A woman may be delivered while under the influence of eclampsia, which might have attacked her before labor set in; and after delivery, but before complete recovery, she might become maniacal—a not unfrequent condition—during which interval she may have killed or injured her child; or the child may have been born dead, or suffering from some accidental injury. She would with truth assert her entire ignorance of it. Her statement would be verified by a bitten tongue, a congested conjunctiva or face. Should albumen be found in the urine this fact would be still more confirmative. Of course, eclampsia might occur without these results. The statement might be disproved by finding that her actions had shown care and design in other circumstances at the time she said she was unconscious. Mr. King has described the case of a woman, aged 36, the mother of nine children. She received his assistance in her tenth labor; when summoned, she was lying calmly and placidly in bed, and was perfectly insensible. He found that the child had been expelled with the placenta. The woman did not recover her sensibility for ten or twelve hours, and then stated that she had no recollection either of the birth of the child, or of any circumstances connected with this event; she suffered no pain or uneasiness. Another case is mentioned by this gentleman, in which sensation appeared to be entirely paralyzed during labor. (*"Med. Times,"* May 15, 1847, p. 284.) It is beyond doubt that profound lethargy occasionally makes its appearance about the time of delivery. Dr. Schulze met with a case in which a woman remained in a state of sleep for three days, and was delivered while in this unconscious condition; on awaking, she had no recollection of having suffered any pain during delivery. (*"Ann. d'Hyg.,"* 1845, vol. 1, p. 216; *"Med. Gaz.,"* vol. 36, p. 40.) Dr. Montgomery relates the case of a lady, the mother of several children, who, on one occasion, was unconsciously delivered during sleep. (*"Uyc. Pr. Med.,"*; see also case in *"Brit. and For. Med. Rev.,"* No. 9, 256.) Dr. Palfrey describes a case in which labor commenced and progressed

in a woman to the second stage during sleep. ("Lancet," 1864, vol. 1, p. 36.)

The results obtained by the use of the vapors of chloroform and ether show that the expulsive efforts of the uterus are often as energetic in the unconscious as in the conscious state. It may appear extraordinary, however, that a primiparous woman, unless rendered unconscious by narcotic substances, should be delivered without suffering pain; nevertheless, a case of this kind is recorded by Dr. Wharrie. The woman's age was 21; she had been in labor about six hours; she complained of no pain, and the child was born without effort or consciousness. The child was healthy but small, weighing rather more than four pounds. ("Cormack's Journal," January, 1846, p. 12.) Notwithstanding this case, it is in the highest degree improbable that any primiparous female should be delivered during *ordinary sleep*, without being roused and brought to a sense of her condition.

There is another condition in which a woman may state that her delivery took place unconsciously; and this, from its being one of the most common species of defence set up by a female charged with child-murder, must here claim our attention. Thus, she will allege that, while suffering from pain, she felt a strong desire to relieve her bowels; that she went to the closet for that purpose, and was there delivered without knowing anything of the occurrence, until it was too late to save the child. This kind of desire is a very common symptom of the parturient state; and in private practice it is often difficult to restrain a woman from yielding to the feeling, when it certainly would be attended with hazard to the child. ("Med. Times and Gaz.," April 4, 1857, p. 347.) We must therefore admit that an accident of this kind can occur; although here, as in every other instance in which unconscious delivery is pleaded, a medical witness ought to inform himself, or be informed, of all the particulars which are stated to have attended delivery, before he gives an answer applicable to the case. As a general rule, it cannot be denied that delivery may take place under these circumstances, and a woman not be conscious of it; but before we make this admission in regard to any particular instance, we ought to have a statement of all the facts from the female herself. It is thus that we shall avoid the risk of seeing a premature medical opinion set aside by the subsequent production of circumstantial evidence. Besides, it has been properly observed, that *after* an accident of this kind, a woman cannot be ignorant of her having been delivered. Women who have raised this plea in cases of child-murder, have often been known to maintain that they were unconscious of their pregnancy, and thus have attempted to excuse themselves for not having prepared the articles necessary for child-birth. It is possible that a woman, especially one who is pregnant for the first time, may not be aware of her pregnancy in the earlier stage; but it is rare for one to advance to the full term without being conscious of it. Women who have borne children have not unfrequently consulted medical men; and although nearly at full term, they have been unconscious of their state. In the majority of instances, it may be presumed that a woman thus situated must have some reason to *suspect* her condition; and if only a suspicion existed in the mind of one who did not contem-

plate the destruction of her offspring, there would assuredly be many circumstances forthcoming which would at once establish her innocence. If this remark applies to married women, it applies with still greater force to those who are unmarried, since the fact of illicit connection, and the fear of its consequences, must render them peculiarly alive to all those changes which, by common repute, take place in the female system during pregnancy.

Post mortem parturition.—Several instances of this kind have been recorded ("Med. Press," Oct. 9, 1872), and they have all arisen from the same cause—the extrusion of the foetus from the relaxed uterus, as a result of the accumulation of the gases of putrefaction. Post-mortem parturition formerly gave rise to many superstitious notions, but the facts connected with this condition are now fully understood. (See "Lancet," 1872, 1, 596.) If the body is not in a decomposed state, it is unusual to find the uterus retaining the power of expelling the foetus by its own muscular contractions after the death of the woman. It is obvious that in certain cases this condition might be used to cover and conceal a case of criminal abortion. This subject has been lately brought before the Medico-Legal Society of Paris by my friend Dr. Louis Pénard. ("Ann. d'Hyg.," 1873, 1, 213.) He was required to report on an alleged case of delivery thirty-six hours after the death of the woman, in which the question of expulsion by gaseous putrefaction could not arise. In July, 1872, a young woman died under suspicious circumstances, after eight days' illness. It was only just before her death that the medical man in attendance discovered that she was pregnant, and had probably reached the fifth month. He made no examination after death, and when the body was laid out there was no unusual appearance. When raised to be placed in a coffin, thirty-six hours after death, a foetus fell from between the legs of the woman. On examining the body the uterus was found with the placenta attached, inverted and extruded from the outlet. Dr. Pénard, after fully considering the case as submitted to him, came to the conclusion that after the death of the woman, the uterus would not retain the power of expelling the foetus, and inverting itself by spontaneous muscular contraction. No doubt there are great difficulties in admitting that a spontaneous action of the uterus after the death of the woman should be so powerful as not merely to expel the foetus and placenta, but actually to invert or cause prolapsus of the organ; still the occurrence of such cases rests upon good authority. (See "Obstetric Transactions," 1873, p. 255.) In these rare instances, it is probable that the woman had reached the full term, and parturition might have commenced before death. In the case related by Dr. Pénard, the woman had only reached the fifth month, and at this stage of pregnancy it is improbable that the post-mortem contractions of the uterus, without any assignable cause, would have operated to expel the child and invert the organ. It is more reasonable to suppose that in this case there had been criminal interference. ("Lancet," 1872, 1, 517, 596, and 2, 119.) The subject of post-mortem parturition has been lately brought before the Obstetric Society by Dr. Aveling ("Obstet. Transactions," 1873, 14, 240), and he has here reported thirty cases of this kind. The principal conclusions at which he has arrived are that the

uterus may expel its contents after death, save in cases in which no symptoms of natural parturition can be discovered before death. He also considers that expulsion of the placenta, spontaneous evolution of the foetus, and prolapsus, inversion and rupture of the uterus, may equally take place post-mortem. He refers these effects either to a contracting power remaining in the uterus after the death of the rest of the body, or to the pressure exerted on the uterus by the gases of putrefaction, the latter being the more frequent cause. His cases have also led him to a conclusion having an important bearing on the medico-legal relations of this subject—that after the death of the woman, a child may continue to live in the uterus for many hours; but when a woman dies undelivered, no time should be lost in removing the foetus. (Op. cit., p. 255.)

Signs of delivery in the dead.—It will now be proper to examine the signs of delivery which are derivable from an examination of the body of a woman after death. Occasionally we may obtain some history of the case during life, by which our labor will be much facilitated; but, on the other hand, every fact may be studiously concealed from us, and then we may be required to prove not only the delivery, but the previous pregnancy. These investigations relative to pregnancy and delivery in the dead body, are almost exclusively confined to cases of criminal abortion, where the contents of the uterus have been expelled at the sacrifice of the life of the woman. Death commonly ensues in these cases within two or three days after delivery, and then satisfactory proofs are obtainable by a post-mortem examination; but if the woman has survived three or four weeks, it will be as difficult to determine delivery in the dead as in the living subject. This remark applies to the delivery at the full period; for if the uterus have expelled its contents in the first months of pregnancy, the traces of this expulsion will have generally disappeared in the course of a few days.

The following may be taken as the chief appearances when the body of a woman is examined soon after delivery at the *full* period: The uterus is like a large flattened pouch, from nine to twelve inches long, its mouth being wide open. The cavity contains coagula of blood or a sanguineous fluid, and its surface is covered with the remains of a decidua—the outermost membrane of the embryo or foetus. In the part to which the placenta has been attached the substance of the organ appears exposed, presenting several large semilunar or valvular openings. This portion of the uterus has been found of a very dark color, which has given rise to a suspicion that the organ was gangrenous. The vessels are extremely large and numerous. The Fallopian tubes, round ligaments, and ovaria are so vascular (full of blood) that they have a purple color. The spot whence the ovum has escaped is more congested than the rest of the ovarian surface. Obstetric writers differ greatly in their statements respecting the size of the uterus at different periods after parturition; and these differences may be explained, partly by the fact that the uterus contracts more rapidly in some women than in others, and partly perhaps by the circumstance of the birth having been, in some instances, premature. M. Toulmouche has reported some instructive

cases of delivery at different periods, showing the influence of time on the appearances. ("Ann. d'Hyg.," 1864, 2, p. 349.)

Dr. Montgomery states that after delivery at the full period, and under perfect contraction of the uterus, if the body be examined within a day or two, the uterus will be found seven inches long and four broad. Its substance, on making a section, will be from an inch to an inch and a half in thickness, and will present the orifices of a great number of large vessels. At the end of a week the uterus is between five and six inches, and at the end of a fortnight about five inches in length; the density of its structure has during this period increased, but its substance has considerably diminished. The inner surface is still bloody, and covered partially with a pulpy membrane resembling the decidua. The orbicular direction of the fibres around the internal orifices of the Fallopian tubes is at this time very distinct. In about a month the uterus will have become fully contracted; but the mouth rarely, if ever, closes so completely as in the virgin state. In a case examined by Dr. Barnes, in which a primiparous woman, aged 26, died from puerperal fever on the *sixth day* after delivery, the following appearances were met with in the uterus: The internal surface was blackened and congested, especially in those parts to which the placenta had been attached. There was the appearance of suppurative action in this part. The substance of the uterus was healthy; there was no pus in the sinuses. The os uteri showed considerable ecchymosis. The vagina was healthy; the iliac veins contained nothing but loosely coagulated blood. There was in the left ovary a small well-marked corpus luteum, having a central cavity. ("Med. Gaz.," vol. 41, p. 294.) This condition of the uterus must not be confounded with the appearances which are observed when death takes place during *menstruation*. Dr. Judee found in the bodies of three women who died during menstruation that the uterus was somewhat enlarged—its walls being thickened and its interior lined by a reddish gelatinous layer about 1-12th of an inch thick consisting of a capillary network of vessels, inclosed in a mucous-like membrane. When this was removed the uterus below was found to be white and firm. The interior of the neck was of a grayish color; the lips were swollen, of a dull-red, bluish, or even black color. On compressing this part small drops of blood issued. This was not observed either in the neck or body of the vagina. A section of the uterus presented only the normal fibrous tissue; but at the level of the mouth (os uteri) there was a mass of tissue resembling a portion of an apoplectic lung. The blood during menstruation, according to this gentleman, issues entirely from the highly congested mouth of the uterus. ("Gaz. des Hôpitaux," No. 39; and "Med. Times and Gaz.," June 23, 1855.) An ecchymosed condition of the neck of the uterus is very commonly found as the result of even an easy labor, and therefore forms a good guide where present. This point must be borne in mind in reference to criminal abortion, inasmuch as the neck may present an appearance as if violence had been employed.

From the statement of appearances given above, it will be seen that there must be considerable difficulty in determining the period prior to death at which delivery took place. The difficulty is increased when a

woman has been prematurely delivered, or when death has not taken place until some time after delivery. A medical opinion may be then in some degree strengthened by searching for those signs which have been described as characteristic of delivery in the living. These, if present, will always furnish strong corroborative evidence, not only of the fact of delivery, but of the period at which it had probably occurred.

Parity and nulliparity.—The medical question whether a woman has ever borne a child or not may be material in reference to proof of identity. In *Reg. v. Wainwright* (C. C. C. Dec. 1875), the charge against the prisoner was that he had murdered Harriet Lane, a woman with whom he had cohabited. She had been missing a whole year, and the remains of a woman were found buried in premises belonging to the prisoner; they had been cut up into various portions, and were so mangled and decomposed that it was necessary to establish the identity of the body as that of the missing woman. One of the medical points raised referred to the condition of the uterus—*i. e.*, whether the appearances which this organ presented were such as to indicate conclusively that the deceased had borne children. The missing Harriet Lane had had two children by the prisoner, the last having been born some time before Christmas, 1873; therefore, about nine months previous to her disappearance. From their examination of the uterus, Mr. Larkin and Mr. Bond came to the conclusion that this woman had borne a child. On the other hand, Dr. Alfred Meadows, who appeared as an obstetric expert for the defence, stated that, in his opinion, the woman of these remains had never borne a child. He qualified this opinion, however, by stating that he believed it to be impossible to decide this question in any case with absolute certainty. If this witness had been able to swear positively that the indicia of childbearing were absolutely certain, and could never be mistaken for a virgin or unimpregnated state of the uterus, his evidence would have gone far to show that this could not have been the body of Harriet Lane. He felt, however, he could not carry his evidence to such an extent, and the effect of it simply amounted to a difference of opinion on the answer to this question. (“*Brit. Med. Journ.*,” Dec. 11, 1875.) Dr. Lutand has recently brought this subject before the Medico-Legal Society of Paris, but without eliciting any conclusive facts to aid the obstetric expert in forming an opinion in any future cases. (“*Ann. d’Hyg.*,” Jan. 1880, p. 57.)

The condition of the uterus, according to the evidence for the prosecution, was inconsistent with virginity. This organ was in every way enlarged. It was flaccid, and the walls were unusually thin. There were one or two white lines (*lineæ albicantes*) in the skin of the lower part of the abdomen, and other marks of a darker color in the inguinal region. The obstetric expert for the defence considered that the shape of the uterus and thinness of its walls, indicated that the deceased was nulliparous, *i. e.*, that she had never borne a child. The evidence of the medical witnesses for the prosecution was strongly corroborated by a number of facts tending to prove that this was the body of Harriet Lane, and the prisoner was convicted and executed. It would appear from the discussions on this case which took place at the meeting of the Obstetric Society, that medical science alone cannot at present furnish a certain

answer to this question. ("Trans. Obstet. Soc.," 1876, vol. 17, p. 355, and vol. 18, p. 69; also, 1879, vol. 20, p. 172.) The characters usually assigned—thickness of the uterine walls, arching of the fundus, the altered form of the recti and of the uterus, and the shape of the os tincæ may arise from other causes than pregnancy. Dr. Williams believes that the increased size and number of the uterine arteries affords presumptive, but not absolute, evidence of a woman having borne a child. In April, 1879, a woman was convicted of a fraudulent attempt to extort money from a gentleman under the pretence that she had been recently delivered of a child, which she threatened to have affiliated on him. On examination, it turned out that she had not been delivered of a child.

Corpora lutea.—The condition of the ovaries has been considered to furnish strong evidence, not so much of delivery as of previous pregnancy. These organs, as it has been already stated, when examined soon after delivery, are found of a deep purple color, owing to their extreme vascularity. If the woman has really been pregnant, we may expect to find, on one of the ovaries, the appearance which is denominated a *corpus luteum*. The accounts given by obstetric writers of the characters of corpora lutea, and the evidence which they are capable of furnishing in legal medicine, are very conflicting. According to Dr. Montgomery, in a *true corpus luteum* (*i. e.*, of pregnancy) the ovary presents a protuberance with a distinct cicatrix on the part whence the ovum has escaped. The protuberant portion will be found on section to have an oval form and to be of a dull yellow color—hence the name *corpus luteum*. It is full of blood, and in texture resembles the section of a kidney. It is of its greatest size in the early stage of pregnancy, and gradually diminishes as gestation advances. In the centre of this section there may be either a *cavity* or a radiated white *cicatrix* (scar), according to the period at which the examination is made. The cavity remains for about three or four months after conception, and is surrounded by a strong white cyst; as gestation advances, the opposite sides approximate, and a radiated white cicatrix results. The size and vascularity of the corpus luteum are considerably diminished by the time gestation is completed, and in about five or six months afterwards—*i. e.*, fourteen months after its first formation—it disappears altogether from the ovary; so that the corpus luteum of one conception is not found with that of another, unless a premature expulsion of the contents of the uterus has taken place. ("Cyc. Pr. Med.," Pregnancy, p. 496; see, also, "Edinburgh Monthly Journal," Jan. 1845, p. 58.) The presence of a corpus luteum, as it is here described, does not prove that a woman has borne a child. In the opinion of some obstetric authorities, it establishes that conception had taken place; but the embryo may have been converted into a mole or a blighted foetus, and expelled at an early period.

The late Drs. Baly and Kirkes, who investigated the subject of true and false corpora lutea, concluded from their researches, that cases seldom occur in which the mere presence of a corpus luteum can be taken as a proof of previous impregnation; and they consider the following rules to be deducible from the facts which they have collected: 1. A corpus luteum in its early stage (that is, a large vesicle filled with coagulated blood, having a ruptured orifice, and a thin layer of yellow matter

within its walls) affords no proof of impregnation having taken place. 2. From the presence of a corpus luteum, the opening of which is closed, and the cavity reduced or obliterated (only a stellate cicatrix remaining), no conclusion as to pregnancy having existed can be drawn, if the *corpus luteum* be of small size, and does not contain so much yellow substance as would form a mass the size of a small pea. 3. A similar corpus luteum of larger size than a common pea would furnish strong *presumptive* evidence, not only of impregnation having taken place, but of pregnancy having existed during several weeks at least; and the evidence would approximate more and more to complete proof, in proportion as the size of the corpus luteum was greater. (Op. cit., p. 57.)

From these considerations, therefore, it appears to me that the only conclusion which we can draw is, that medical evidence respecting the nature of a corpus luteum in an unknown case, if received by a court of law at all, should be received with the greatest caution, and only from a witness of great experience. The old doctrine on this subject, that the presence of such a body on the ovary affords *certain* and undeniable evidence of impregnation, may be regarded as completely subverted.

Characters of the ovum or embryo to the sixth month.—Hitherto the examination has been confined to the woman, but it is now necessary to describe the characters of the ovum or embryo and its enveloping membranes at the early stages of pregnancy, since when this can be procured it may furnish good medical evidence. The “ovum” signifies the embryo and its membranous coverings; the “embryo” is the body which is afterwards converted into the foetus; the term “foetus” is applied to the embryo after the third or fourth month of gestation. If the ovum be expelled within a *month* after conception, it is scarcely possible to detect it, owing to its small size and its being enveloped in coagula of blood. Burns examined three uteri within the first month, where no expulsion had taken place, but even under these favorable circumstances he failed to discover the ovum. At first the ovum contains no visible embryo, but it appears merely to consist of vesicular membranous coverings. According to this authority, when first distinctly seen through its membranes, it is of an oblong form and about a line (the twelfth of an inch) in length. At the *sixth week* it was slightly curved, resembling, as it floats, a split pea. In the *seventh week* it is equal in size to a small bee; and by the end of the *second month* it is bent, and is as long as a kidney-bean. After the second month development goes on rapidly; the features are in part well-marked, and the limbs are gradually formed. At the *third month* the foetus weighs from one to two ounces; when stretched out it measures about three inches, and the genital organs, although the sex is not then distinguishable, are large in proportion to the rest of the body. The membranes are larger than a goose’s egg. At the *fourth month* the foetus is from five to six inches long, and weighs from two to three ounces; at the *fifth month* it measures from six to seven inches, and weighs from five to seven ounces; and at the *sixth month* its length is from eight to ten inches, and its weight about a pound. (For the characters of the child beyond this period, see “INFANTICIDE.”) The great difficulty will consist in determining the nature

of the supposed ovum or embryo between the second and third months. In making the examination, the ovum should be placed in water, and all coagula gently washed away from the membranous coverings or removed by some blunt instrument. Alcohol may be used as a substitute for water, after the blood has been removed. If the embryo cannot be found, the decidua and chorion, or portions of them, may be recognized:—the former by its forming the outer investment with its smooth internal, and rough external or uterine surface; the latter by the villous or shaggy appearance of that portion of it which would have become the placenta. Between the third and fourth month the foetus may be commonly identified without much difficulty. The ovum in many instances escapes first, leaving the decidua behind. This comes away after a time, but it is important to remember that in some states of the virgin decidua-like structures are thrown off from the uterine mucous membrane, which, when examined by the microscope, resemble the true decidua. Both are constituted of the innermost portion of the uterine mucous membrane, and contain all its elements. Dr. Keiller ("Ed. Med. Jour.," July, 1865, p. 82) and Dr. C. Bell, in the same journal (Aug. 1865, p. 120), have called attention to the fact that an erroneous medical opinion on the date of pregnancy may be formed by trusting too much to the appearance of the ovular membranes. The ovum or foetus may die, and the membranes afterwards continue to grow, thus giving the appearance of a longer date to pregnancy. An examination of the embryo alone can give any satisfactory results on this point. The membranes may be also enlarged as the result of dropsical accumulation, and this may be set down to pregnancy of some duration, when it may not actually have extended beyond the second or third month.

Moles.—The true mole is the result of conception, the foetus of which has died in consequence of the effusion of blood into the decidua and the various membranes, and (should a placenta exist) into its structure. The sac of the amnion has frequently burst, and the ovum has escaped; or it has died and been dissolved by the liquor amnii or serous liquid, which is found turbid. The remains of the umbilical cord are frequently found on the interior of the animal sac. Nodules are found projecting into the cavity, which are produced by the effusion of blood outside the sac. Sometimes the cavity is almost obliterated, the main bulk being made up of effused blood. In the varieties of moles it is not difficult to recognize all the membranes; the microscope will always enable the examiner to detect the chorion villi. Such a mole, of course, proves conception; but solid bodies are expelled from the uterus which have not this origin, and may occur in the virgin: these are called *false moles*. A clot of blood may become dense, and, losing some of its coloring matter, exhibit appearances which cannot be distinguished from the true mole except by the microscope. *Polypi* may also resemble a mole; but a careful examination would readily show the absence of ovular membranous structures. Sometimes a large exfoliation of the vaginal epithelium may take place, and before its expulsion become condensed, so as to cause suspicion. The microscope will, however, show that it consists of only tessellated epithelium. Moles may coexist with true pregnancy, in a case of

twins. The symptoms accompanying a mole resemble those of pregnancy; and the appearances produced by its expulsion are not to be distinguished from those attending the abortion of a foetus at an early period of gestation. The only means of distinction would be derived from an examination of the expelled matters. The local injury produced by the expulsion of these bodies on the organs of generation is by no means as great as that caused by delivery at the full period.

Vesicular mole (Hydatiniform degeneration of the chorion).—When by some accident the foetus dies at any time before the complete formation of the placenta, the villi of the chorion, instead of completely dying, retain a certain amount of vital force; the consequence of which is that in some parts growth goes on imperfectly, serous fluid is effused within, and the part is distended into a globular form. This, occurring frequently in the course of each villus, gives it a beaded appearance, and the whole mass appears something like a bunch of grapes. The size, however, of each vesicular body varies much in different specimens, and also in different portions of the same specimen, some being only detectable by the microscope, while others are as large as the largest grape. On the largest kinds are generally to be found small villi, undergoing more or less the same process of change.

Thus it will be observed that the vesicular growths are attached one to another by delicate threads—the unchanged stem of the villus. This will readily serve to distinguish them from true *hydatids* (Dr. Graily Hewitt, “Obstetric Transactions,” vol. 1, p. 249), concerning the distinction between which much confusion has existed, and questions have arisen as to whether the vesicular mole can exist, or be produced in the virgin. From what has just been shown, it will be perceived that this latter cannot arise except as a result of impregnation. It is exceedingly rare to find *true* hydatids in the uterus at all, still more so for them to be discharged through the cavity of the uterus. Dr. Hicks informs me that no authentic account of such a case is on record. But even if it were not so, the slightest examination by the unaided eye would show whether the vesicles were attached to each other as above mentioned, or whether the smaller were inclosed within the largest cyst, or floating without any attachment whatever. The use of the term “hydatid” does much to perpetuate the error. How long this vesicular mole may remain in utero is uncertain; accurate information is required on this point. Certainly it may remain more than a year, and possibly many years. The rapidity with which they grow is very great, but this is readily explained by the fact that it is a simultaneous enlargement of myriads of parts. A woman at the third month of pregnancy may be as large as at the seventh month; she may ultimately attain a size exceeding that of the full term. Cases of twin-conception are not uncommon, in which one ovum becomes vesicular, the other going on towards maturity. (Dr. Hall Davis, “Obstetric Transactions,” vol. 3, p. 177.) Again, one ovum may become vesicular, while the other is converted into a fleshy mole. In some rare cases, a portion only of the chorion is changed into this form of mole, while the proper formation of the placenta may go on in the normal manner.

The question here arises—Can the mature placenta be so converted?

Should a portion be left behind in a healthy state, can it assume the vesicular degeneration? From all that is at present known, this is exceedingly improbable; from observations made of late years, it appears that the change only takes place in the *chorion* villi before the formation of a placenta. It is much more probable that, should a woman have no intercourse after labor, but yet expel a true vesicular mole, that it was a twin ovum which was not expelled during labor. In an early stage of pregnancy, a decidual covering will always be found, more or less complete, around the mole; but if the size of the mass is great, then, although present, it will be less observable, being spread over a larger surface. A *corpus luteum* will also be found, but not so perfectly formed as in normal pregnancy.

The ordinary symptoms of pregnancy accompany this state, although in all forms of mole-pregnancy it is imperfectly marked, or only proceeds to a certain point. (See case "Obstetric Record," vol. 1, p. 21.) It is also to be remembered that the effects of the expulsion of a mole are very similar to those of abortion. These facts may have an important bearing on medico-legal practice, and in this respect the following case, reported by the late Dr. Chowne to the Westminster Medical Society, November, 1844, will be found of interest: A woman was seized with pains resembling those of labor, and a mass of uterine hydatids was expelled, which was supposed to have been in the uterus about five months. When the woman was examined about thirty-six hours afterwards, there were all the signs of recent delivery about her. The parts of generation presented the usual appearances met with in the expulsion of a foetus: the breasts were enlarged, the areolæ elevated, of a brown color, the follicles prominent, and the organs evidently containing milk. The occurrence of this case led Dr. Chowne to think that, had the body of an infant been found with marks of violence upon it, concealed in the house where this woman had lived, it would probably have been pronounced to have been her child. A medical man might have strengthened the suspicion of criminality by declaring that there were all the signs of recent delivery about her. It may be observed, however, that in such a case the woman would probably have stated that no child, but some tumor, had come away from her; and a medical man would not be justified in swearing that appearances of delivery absolutely indicated, under all circumstances, that a woman must have been delivered of a *child*. On the contrary, it is a well known medical fact, that similar appearances may arise from the expulsion of the various forms of mole. (See a case of Mr. Pearson's, "Medical Times," Dec. 30, 1848.) Circumstantial evidence would be against her only on the assumption that some person had wilfully concealed or made away with substantial proofs of her innocence, *i. e.*, the mass which had been expelled. Dr. Fischer met with a case in which a woman gave birth secretly to a child, whose death led to a charge of child-murder against her, and two months afterwards she passed a mole or blighted foetus, in reference to which a question of superfoetation was raised. (Horn's "Vierteljahrsschrift," 1866, 2, 22.)

Sometimes in cases of abortion, portions only of the placenta can be obtained. A question will here arise as to the date of pregnancy indicated by the size and condition of the placenta. Dr. Maurice Longuel

describes a case of this kind, and he was enabled from an examination of the placenta to state that the pregnancy dated from the second to the fifth month. ("Ann. d'Hyg.," 1879, 1, 365.)

Concealment of birth.—Medical evidence respecting delivery is required in two cases: 1st, when the birth of a child is wilfully concealed; and 2dly, when the contents of the uterus have been prematurely expelled by criminal means. The concealment of pregnancy is no offence in the English law; but the concealment of *delivery* or of *the birth* of a child is a misdemeanor by the 24 & 25 Vict., c. 100, sec. 60, the words of which are to the following effect:—"If any woman shall be delivered of a child, *every person* who shall by *any secret disposition* of the dead body of the said child, whether such child died before, at, or after its birth, endeavor to conceal the birth thereof, shall be guilty of a misdemeanor." The late Mr. Justice Willes remarks upon the statute that women tried on this charge are punished, not for concealment of birth, but for concealment of the body; a distinction which not only increases the difficulty of obtaining evidence, but excites hopes in the criminal that, if she can finally do away with the body, she may be free of the law. Various interpretations have been put upon the terms "concealment" or "secret disposition" of the body. This part of the evidence does not affect a medical witness, unless he himself has found the dead body, or was present when it was found. It will rest with the judge to determine whether the body was so disposed of as to constitute legally a misdemeanor. (*Reg. v. Clarke*, Chelmsford Summer Assizes, 1864.) Under the new criminal code it is proposed to enact, in reference to concealment of birth, that the crime is complete in disposing of the dead body of a child in any manner, with intent to conceal the fact that its mother was delivered of it.

Medical men must be cautioned here, as in some other crimes committed by women, that they have no legal right, except by the consent of the woman, to examine her person in order to ascertain whether she has been recently delivered or not. According to English law, no person is bound to furnish evidence against himself. A medical man who neglects this rule may find himself charged with an indecent assault, and be sued for damages.

In *Agnew v. Jobson* and others (Newcastle Lent Assizes, 1877), plaintiff was suspected of concealing the birth of her illegitimate child, of which she was afterwards convicted. An inspector of police, wishing to have evidence of her physical condition, gave to Dr. Mackay authority to examine the plaintiff's person. Having some doubt about the legality of the proceeding, he applied to the defendant, Jobson, a magistrate, who gave him a written order for the purpose. Mr. Jobson, Dr. Mackay, and another were sued for damages for an indecent assault. The evidence made it clear that the girl did not give her consent, but her alarm prevented her from resisting. The judge summed up, and the jury returned a verdict for plaintiff of 50*l.* damages. ("Brit. Med. Jour.," March 17, 1877.) A medical man may, however, examine the clothes of the accused, as well as the body of the child, if they are handed to him by the police for this purpose.

This is an offence of which women charged with child-murder are

commonly convicted in England: while the Scotch law punishes women for the concealment of pregnancy, if the child be dead or amissing. (Alison's "Criminal Law," p. 153.) The medical evidence on trials for this misdemeanor is exclusively derived from an examination of the mother; and thus, much will depend upon the time at which this is made. With respect to the child, its body need not even be produced, provided there be satisfactory evidence of its death; the body may have been secretly buried or burnt, and in the latter case it may be necessary to examine the bones or ashes.

According to the statute the child must be *dead*—the concealment of the birth of a living child not being any offence, unless it should happen to die before its birth was made known. In the case of the *Queen v. Woodman* (Kingston Lent. Ass., 1845), the woman was acquitted because the child was living when concealed. Mr. Chitty says that, in order to constitute the offence, the child must have advanced to the end of the seventh month ("Med. Jur.," p. 412); but it is to be presumed that the concealment of the birth of a dead child at the sixth, or under the seventh month, would be as much an infringement of the statute as if it were more advanced. The concealment of the aborted but undeveloped ovum or embryo—of a monster, *i. e.*, a child without human shape, a mole, or other morbid growth—would not probably be considered a contravention of the statute. I am not aware that there has been any judicial decision on this point. Mr. Lane communicated to the "Medical Times" (August, 1845) a case in which a charge of concealed birth was dismissed by the magistrates of Surrey, because the concealment referred to a child born at the eighth month *in its membranes*. The woman stated that she did not consider it to be a child! If this decision is correct, the main object of the statute (*i. e.*, to prevent secret delivery, so often leading to murder) may be effectually evaded. The case, being entirely new, should have been sent for trial, and the decision left to the proper interpreters of the law; a magisterial decision can furnish no precedent on a question of this kind. This woman must have been delivered of a child, foetus, or embryo, or of course there would have been no pretence for the charge. That a child may be thus born, and removed from the membranes alive, is a fact established by experience. Dr. Brunton reported to the Obstetrical Society a case in which the entire ovum was expelled at the seventh month of gestation, and the child was rescued alive, although born fifteen minutes before being taken out of the membranes. ("Med. Times and Gaz.," 1871, 1, 412.) In another case of sudden delivery, the child in its membranes, with the placenta, was discharged into a bucket. It was not rescued in time to save life. ("Amer. Jour. Med. Sci.," April, 1870, p. 430.)

From some observations made by the Recorder of London at the Central Criminal Court, October, 1865, there appears to be some uncertainty on this point. Thus, it is difficult to suggest a proper legal definition of a "child." In reference to the case of *Reg. v. Knight*, a woman charged with concealment of birth, the prisoner admitted to a policeman that she had been delivered of a "something" (not forthcoming). "Now, was she delivered of a child, and had she disposed of the body in such a way as to conceal the fact of her having been so delivered? Then, what was

'a child'?—for those were the words used in the Act of Parliament. He felt himself a little debarred from expressing his own opinion in reply to this question, because two of the learned judges had given decisions directly contrary the one to the other upon this subject. One of them said it was not a child unless it had attained that state in which it could live, supposing it had been born alive. If it had attained that state, then he was of opinion that it was a child. The other judge said that this was not his idea of a child; but that if it had the outward form of a child, it was a child according to the Act of Parliament. The one contended that it ought to have attained to a state in which it had a capability of living (*viability*); and the other that at any rate it should have the outward form of a child. Was there any proof of this kind here? The prisoner herself said she did not know whether she had been in the family way for three months. Taking the widest view of the learned judges,—Had what was born in this case the outward form of a child?—If it had not, then the prisoner was not guilty of the offence charged against her."

The proposed new Criminal code contains this provision (section 146):—No foetus shall be deemed to be a child within the meaning of this section which had not, when born, reached the period at which it might have been born alive. This, as it will be seen under INFANTICIDE, is not a fixed period, but no doubt the earliest period at which a child has been known to come into the world living, will be taken as the limit.

It will be perceived that it is not material here, as in a case of alleged infanticide, to prove *when* the child died—whether before, during, or after its birth; and thus those subtleties and technicalities which are met with in cases of child-murder are avoided. In regard to proof of concealment, and what constitutes it, these are essentially legal points; but a medical practitioner may sometimes benefit an accused person, if he can prove that the woman had made application to him on the subject of her pregnancy and delivery. The law is especially lenient under such circumstances. A very strict interpretation appears to be put upon this term *concealment*. There must at present be a "secret disposition" of the dead body. Under the new Criminal code, section 146 punishes the disposing of the dead body of a child in any manner to conceal the fact that its mother was delivered of it. This provision does away with the technical difficulties which have hitherto attended the proof of concealment. But the medical witness may have to deal not with the body, but with the remains in a mutilated state, or burnt. He must be able to prove that they really are *human* remains. In a case tried at the Cornwall Summer Assizes, 1871, the prisoner, a married woman, was charged with the murder of her illegitimate child. The body was found mutilated, and partly burnt. The woman had concealed the mutilated body of the child, and had tried to get rid of it by burning. She said the burnt bones found, and some blood on a rug, were those of a fowl. Mr. Hudson (of Redruth), however, proved that they were the bones of a child, and that the blood was not that of a fowl.

Questions connected with concealment of birth do not fall under the jurisdiction of a coroner:—the medical evidence is therefore required by

a magistrate. Medical witnesses were formerly exposed to much trouble and inconvenience in giving their evidence on these occasions (see "Med. Gaz.," 19, 287); but the defect has been remedied by statute (1 Vict., c. 44).

CRIMINAL ABORTION.

CHAPTER XLVI.

ABORTION FROM NATURAL CAUSES.—CRIMINAL CAUSES.—MECHANICAL MEANS.—MEDICINAL SUBSTANCES.—SIGNS OF ABORTION.—SPECIFIC ABORTIVES.—LOCAL APPLICATIONS.—FEIGNED ABORTION.—MEANING OF THE WORD NOXIOUS AS APPLIED TO DRUGS.—ON INDUCING PREMATURE LABOR.—PROOF OF PREGNANCY NOT NECESSARY.—ABORTION OF MONSTERS.—MOLES AND HYDATIDS.

By abortion is commonly understood, in medicine, the expulsion of the contents of the uterus *before the sixth month of gestation*. If the expulsion take place between the sixth and ninth month, the woman is said to have a premature labor. The law makes no distinction of this kind, but the term abortion is applied to the expulsion of the foetus at *any period of pregnancy* before the term of gestation is completed; and in this sense it is synonymous with the popular term *miscarriage*. Criminal abortion is rarely attempted before the third month:—it is perhaps most common between the fourth and fifth month, because then a woman begins for the first time to acquire a certainty of her pregnancy. The causes of abortion may be either *natural* or *violent*. The latter only fall under the cognizance of the law:—but a medical witness should be well acquainted with the causes which are called natural, in contradistinction to others which depend on the application of violence. These *natural* causes are sometimes very obscure, and the real cause is thus often overlooked. They are so frequent that—according to Mr. Whitehead's observation,—of 2000 pregnancies, one in seven terminated in abortion. These causes are commonly ascribable to peculiarities in the female system,—to the presence of uterine or other diseases, or to some moral shock sustained by a woman during pregnancy. Any diseases which strongly affect the uterus or general system of a woman may give rise to abortion. An attack of smallpox has been known to produce it; and it has been suggested by the late Mr. Acton that the presence of constitutional syphilis in the father is not only a cause of infection in the offspring, but of repeated abortion in the woman. ("Med. Gaz.," vol. 36, p. 164; Ramsbotham's "Obstetric Medicine," p. 655.) These facts deserve attention, when it is proved that the woman has really aborted, and an attempt is unjustly made to fix an alleged act of criminality on

another. For further information on the numerous natural and accidental causes which may give rise to abortion, the reader may consult the work of Mr. Whitehead ("On Abortion and Sterility," p. 252); and for the effects of undue lactation and diseases of the placenta in causing abortion, the "Med. Times and Gaz.," Dec. 4, 1852, p. 580, and March 19, 1853, p. 302. In considering the operation of these causes, it is proper to bear in mind that during pregnancy the uterus is subject to a natural periodical excitement corresponding to what would have been the menstrual periods, dating from the last cessation. Hence, comparatively trivial causes operating at these periods may lead to an expulsion of the foetus. Dr. Salomon has reported two cases in which premature delivery followed the mercurialization of the system. ("Med. Gaz.," vol. 36, p. 658.) See case by M. Canchois ("Ann. d'Hyg.," Sept. 1879, p. 258), in which a strong decoction of coffee operated as a cause.

The *violent* causes of abortion may be of an accidental, or criminal nature. In general the distinction will not be difficult: the kind of violence, and the adequacy of the alleged cause to produce abortion will be apparent from the evidence. In reference to criminal cases, the causes may be referred either, 1st, to the use of *mechanical* means; or 2dly, of irritating *medicinal* substances acting upon the uterus or bowels. They operate with greater certainty just in proportion as the pregnancy is advanced.

Mechanical means.—Among the mechanical causes may be mentioned—severe exercise, the violent agitation of the body, as by riding or driving over a rough pavement, in which case no marks of violence would be apparent. Any physical shock, sustained by the body, may operate indirectly on the uterus. Violent pressure or blows on the abdomen are sometimes resorted to; but in these cases the marks of violence will be commonly perceptible. Instruments have been devised for the purpose of piercing the membranes, destroying the child, and thereby leading to its expulsion. Devergie speaks of such instruments being well known in England, and of English midwives deriving a living from the practice of this crime. (Op. cit., vol. 1, p. 285.) Although this must be regarded as an exaggerated statement, it cannot be denied that cases have occurred which show that the crime is frequently perpetrated by persons who basely derive a profit from the practice: and for one case that comes to light, probably a dozen are effectually concealed. In the evidence given on four trials within a recent period, the cases presented no feature of novelty or interest. Instruments were employed, and drugs in large doses were proved to have been administered.

Mechanical means are undoubtedly more effectual in producing abortion than medicinal substances; yet, from the fact of such attempts being made by ignorant persons, the woman generally dies from inflammation of the womb or peritoneum, or other serious after-consequences. A case was tried some years since, in which the evidence showed that the prisoner had attempted to produce abortion in the deceased, by thrusting wooden skewers into the substance of the uterus. Inflammation and gangrene took place, and the woman died. The prisoner was convicted, and executed for murder. (For a similar case by Mr. M'Pher-

son, see "Med. Gaz.," vol. 36, p. 102; also another case in the same journal, vol. 45, p. 693.) This kind of injury to the uterus always implies the interference of some other person in the perpetration of the crime. Mechanical means can seldom be applied to the uterus without leaving marks of violence on this organ, as well as on the body of the child. If the mother should die, a result which generally takes place, an inspection will at once settle the point. ("Ann. d'Hyg.," 1834, 191; 1838, vol. 1, p. 425; 1839, vol. 2, p. 109.) An important case of this kind was the subject of a criminal trial in Scotland, in 1858 (case of *Reid*, "Medical Gazette," December 11, 1858). The uterus near its mouth presented two openings in its substance, described as punctured wounds by the medical witnesses for the prosecution who made the examination,—and as the openings of torn bloodvessels by others who were called for the defence. There was also a rupture of one ovary. The prisoner was convicted; but the medical man who was supposed to have been the principal agent in the crime committed suicide. The case is chiefly important in showing that any apparent mechanical injury to the uterus, should be minutely examined at the time of the inspection, so that no doubt of the cause may afterwards be entertained by any present. If, in a case of this kind, the mother should survive and the child be expelled, then marks of violence may be found on its body. These marks may not be sufficient to account for its death; but this is not here the question. If it can be proved that they have not resulted from accidental causes during gestation or subsequently to delivery, then their presence may furnish strong corroborative evidence of the actual means by which abortion was attempted. It is said that abortion has been in some instances accomplished by frequent bleeding from the arm. This effect may follow as a result of shock produced by the sudden loss of a large quantity of blood. An examination of the veins of the arms would show whether any such attempt had been made.

There can be no doubt that of all the exciting cases of abortion, the most effectual, and that which most certainly brings on the expulsive action of the uterus, is the destruction of the ovum or embryo. If by accident or design the ovular membranes should become ruptured, gestation is arrested, and abortion necessarily ensues. At any period of pregnancy, therefore, a puncture through the membranes will sooner or later occasion the evacuation of the uterus. (Ramsbotham's "Obstetric Medicine," p. 655.) This author remarks that the performance of the operation demands a most accurate knowledge of the anatomy of the ovum and the maternal structures, as well as of the state of development which the neck of the uterus assumes at different periods of pregnancy. In medical practice, for the induction of premature labor, the membranes are ruptured either by the use of a female catheter, or by an instrument of this shape, but including a blade like a tonsil-lancet. Unless the inner membrane or amnion be opened, gestation may still proceed, and abortion will not take place. When all the membranes are completely penetrated and the waters are discharged, uterine action is invariably induced, but the time which elapses from the performance of the operation to the commencement of labor is subject to great variation. Dr. Ramsbotham states that he has known the uterus begin to act in *ten*

hours after the rupture, but in another case a week elapsed before its action commenced. As a rule, uterine action is in general fully established in fifty to sixty hours. In *Reg. v. Sharpe* (Notts Lent Assizes, 1873), the prisoner, who was a charwoman, but said by profession to be an abortion-monger, was convicted of this crime. It was proved by the evidence of the prosecutrix and others that she ruptured the membranes with an ivory crochet-needle on the 8th November, and on the 11th, three days afterwards, the prosecutrix was delivered of a still-born child. Another woman, proved to be an accessory to the act, was sentenced to fifteen months' imprisonment. ("Lancet," March 22, 1873, p. 422.)

It must not be supposed, however, that where a criminal intention exists, a long period is required for removing the contents of the uterus. The cases above referred to, were cases of obstetric practice in which there was no desire to expose the woman to the slightest risk, and premature labor was openly induced. In a criminal attempt by a medical practitioner, in which the woman would be a consenting party to the act, the removal of the embryo or foetus might be effected in a much shorter period of time. At any rate, the time for the completion of abortion could not be measured by cases in which the uterus has been left to undergo spontaneous contraction after the membranes had been punctured, and the waters had escaped. There would, however, be great danger to a woman in the necessary manipulations required. The reader will find reports by M. Tardieu, of numerous cases of abortion as a result of mechanical means applied to the uterus, in the "*Annales d'Hygiène*," 1855, vol. 1, p. 406; and some good practical remarks by the same writer, on the mode in which these inquiries should be conducted, in the "*Annales d'Hygiène*," 1856, vol. 1, p. 141. On the mechanical means for procuring abortion and the results, see a paper by Dr. Lex (Horn's "*Vierteljahrs.*," 1866, 1, p. 253.)

It is obvious that this mode of perpetrating abortion is only likely to succeed in the hands of persons who have a complete anatomical knowledge of the parts. The certain death of the woman will convert the crime into murder, if instruments are introduced into her body by persons who are ignorant of anatomy. In *Reg. v. Heap* (Liverpool Lent Assizes, 1875), it was proved that prisoner had caused abortion by the use of instruments, and this had led to the death of the woman. On an inspection, two sharply punctured wounds were found in the uterus, and to these death was attributed. The prisoner, although not intending to destroy life, was convicted of murder. A midwife was convicted of a similar crime, at the Manchester Winter Assizes, 1877 (*Reg. v. Cartledge*). The evidence showed that prisoner had introduced an instrument for the purpose of procuring abortion. Inflammation followed, and the woman died in three days from peritonitis and gangrene.

It is to be regretted that members of the medical profession have on several occasions misused their professional knowledge, and have exposed themselves to prosecution for this crime. Sometimes it is probable the charge has been raised falsely, or through misapprehension on the part of the woman; at others, the evidence has left it very clear that the charge was well founded. Of late years medical men have rather freely

used the speculum. When this instrument has been improperly or unnecessarily used on a pregnant woman, a charge of attempted abortion by instruments, may be easily raised against a medical practitioner. A trial took place at the Exeter Lent Assizes, 1854 (*Reg. v. Griffin and Venn*), in which it was charged that the accused, Venn (a surgeon), had feloniously used an instrument with the intent to procure the miscarriage of the prosecutrix. According to the evidence, Venn had on several occasions passed a round polished instrument into the body of the woman, once in a coppice and at another time in a field! The defence was, that the surgeon had merely used a speculum to ascertain whether the girl was pregnant, in order to know how to prescribe for her; and that it was absurd to suppose that he had ever intended to procure abortion, for this had not followed, and it might have been easily produced by him at any period of pregnancy, if the medical man had wished it. The prisoners were acquitted. Admitting the statements of the prosecutrix and the prisoner to be correct, it may be remarked that medical practitioners, in the lawful exercise of their profession, do not commonly use a speculum in open fields or coppices to determine whether a woman is pregnant or not; and it is a well-known fact that a speculum is not necessarily required for determining the question of pregnancy. This case conveys a serious caution to members of the medical profession.

Medicinal substances. Emmenagogues. Ecbolics.—These are more frequently resorted to for inducing criminal abortion than other means; but they rarely answer the intended purpose; and when abortion follows, it is generally at the expense of the life of the woman. Mineral poisons have been ignorantly employed for this nefarious object, and often with a fatal result. Among these substances may be mentioned arsenic, corrosive sublimate, the acid chromate of potash (Horn's "Vierteljahrschrift," 1866, 2, 113), sulphate of copper, copperas or sulphate of iron, the muriated tincture of iron, and other irritants. Metallic *mercury*, which is generally reputed to be innocent, has been given for the purpose of procuring abortion. In a case, recorded by Sir D. Gibb ("Lancet," March 8, 1873, p. 339), it produced no effect on the uterus, but caused some severe nervous symptoms, which would justify the application of the term "noxious" to this substance.

The muriated tincture of iron has frequently caused severe symptoms, and seriously injured health, without producing abortion. In a case in which my evidence was required at the Lincoln Summer Assizes, 1863 (*Reg. v. Rumble*), it was proved that this compound of iron had been given in large doses daily to a pregnant woman, for the purpose of exciting abortion. It had not had this effect, but it had seriously injured the health of the woman. The prisoner also gave to her cantharides in pills. The defence was, that these were proper medicines for the treatment of amenorrhœa, under which it was alleged she was laboring. The large doses administered, and the secrecy with which the medicines were supplied, proved that they had been given unlawfully, and with criminal intent; and the druggist who supplied them, knowing the purpose for which they were required, was convicted.

Arsenic, corrosive sublimate, and other mercurial compounds may cause death, without in any way exciting the uterus to expel its con-

tents. In July, 1845, a case was referred to me for examination in which a woman, who had passed the fifth month of her pregnancy, took a large dose of arsenic, as it was alleged, for the purpose of abortion. She died in less than seven hours, having suffered during that time from severe vomiting and purging; yet abortion did not take place. Such powerful poisons as strychnia have failed to effect it. A girl, æt. 17, who was pregnant, swallowed the contents of a packet of Battle's vermin-killer. The usual symptoms followed, with tetanic spasms and opisthotonos. Under the use of tincture of opium and chloric ether the symptoms were relieved. She recovered and went her full time, without aborting.

Drugs such as croton oil, elaterium, gamboge, and other drastic purgatives, have been used with criminal intent without causing abortion. Aloes and two of its compounds, *hiera picra*—a mixture of aloes and canella bark—and *Pilacotia* (*pilulæ coccia*) sometimes called "pill cochia"—a mixture of aloes and colocynth—are much used as purgatives among the poor. In large or repeated doses, they are supposed to have the power of exciting the uterus, and are secretly employed for the purpose of abortion. Although not poisons in the strict sense of the word, it may be observed of these drugs, and of all purgatives which cause much straining or specially affect the rectum, that they may readily bring on abortion in the advanced stages of pregnancy, while they fail in the earlier stages. The herbs which have acquired a popular repute as abortives, in the form of powdered leaves, infusion or decoction, are very numerous. Some are innocent, such as pennyroyal, broom, and fern; others are pernicious, such as white and black hellebore, yew, and laburnum. A decoction of broom simply acts as a diuretic.

The medicinal substances above described, if they have any effect, exert an indirect action on the uterus by producing a shock to the general system. But there is another class of bodies which are considered to act on the uterus directly. These are classed under the names of *emmenagogues* and *ecbolics*. As in certain trials for criminal abortion some confusion has arisen in the application of these terms (see *Reg. v. Wallis*, Winchester Summer Assizes, 1871), it will be necessary to state here what is understood by them. *Emmenagogues* (from *ἐμμήνια*, the menstrual discharge, and *ἀγωγός*, exciting) signify those medicines which excite or promote the menses. The late Dr. Pereira enumerates among these, savin, black hellebore, aloes, gamboge, rue, madder, stinking goose-foot (*Chenopodium olidum*), gin, and borax; and for the most part substances which when taken in large doses act as drastic purgatives or stimulating diuretics. When amenorrhœa coexists with anæmia the most effectual emmenagogues are chalybeates—the preparations of iron, including Griffith's mixture. ("Elements of Materia Medica," by Taylor and Rees, 4th edit., vol. 1, p. 270.) *Ecbolics* (from *ἐκβολή*, expulsion), substances which cause the expulsion of the foetus, imply medicines which operate directly as *abortives*. They excite uterine contractions, and thereby promote the expulsion of the contents of the uterus, such as the foetus, the placenta, hydatids, clots of blood, etc. The number of ecbolics known is very small. Indeed, the only known unequivocal agent of this kind is *ergot*. The ergot in ordinary use is that of rye: but the ergot

of wheat is said to be equally effectual, and the same perhaps may be stated of the ergots of all grasses.

In addition to these there are other substances derived from the vegetable, animal, and mineral kingdoms, which have been employed for procuring abortion, and on the specific effects of these agents when administered to pregnant women, medical opinions may be required. Such are yew leaves, grains of paradise, tansy, hellebore (white and black), squills, pennyroyal, cantharides, sulphate of potash, borax, Griffith's mixture, and iron filings. The English herbs on which medical opinions may be required, are chiefly rue, pennyroyal, savin, and tansy.

Rue (*Ruta graveolens*).—This common garden plant has been much used in the form of decoction. M. Tardieu has reported three cases in which a strong decoction of rue produced abortion at the fourth, fifth, and about the sixth month of pregnancy respectively, and the women recovered. ("Ann. d'Hyg.," 1855, 1, 408.)

Pennyroyal (*Mentha Pulegium*).—This is a variety of mint. The infusion, under the name of pennyroyal tea, or pennyroyal water, is used as a popular remedy for obstructed menstruation; and it has also been used for the purpose of abortion; but it has neither emmenagogue nor ecbotic properties, and it is not now employed for any purpose by medical practitioners. Any notice of this substance here would have been quite unnecessary, but for the fact that in a recent trial for criminal abortion (*Reg. v. Wallis*, 1871) strongly abortive properties were incorrectly assigned to it; and it was described as a highly noxious substance. Pennyroyal infusion or tea has no more effect on the uterus than peppermint, spearmint, or camphor water. A medical witness at the trial above referred to, stated that pennyroyal would produce abortion, but admitted in cross-examination that he had had no practical knowledge of its properties, and unless taken for some time and of considerable strength, it would have no effect at all.

Medical witnesses should be more cautious in giving evidence on these occasions in reference to the properties of drugs. They have to consider seriously, in all cases of alleged criminal abortion by drugs, whether the substance is noxious—whether it is an emmenagogue, or really an ecbotic. They should base their opinions either on actual personal experience, or on the authority of those who have practically studied the effects of the drugs; otherwise counsel may be greatly misled, as in the case of *Reg. v. Wallis*, in placing the facts before the court. Pennyroyal is not described by any authority as an emmenagogue or ecbotic, or as a substance having any abortive or noxious properties.

Savin (*Juniperus Sabina*), *Oil of Savin*.—The properties of this substance as a vegetable irritant poison have been elsewhere described (*ante*, p. 184). Writers on *Materia Medica* ascribe to it emmenagogue properties, *i. e.*, that it is an excitant to the bloodvessels of the uterus, and is useful in certain cases of disordered menstruation; but it does not excite uterine contractions like the ergot of rye, and it is not used for the purpose of aiding parturition. It should not be given to a woman in the pregnant state, for its operation as an irritant might affect the uterus directly and lead to abortion. It has been long known and employed as a popular abortive, the tops being used in the form of infusion or

decoction: Under these circumstances it commonly acts only as an irritant poison, causing severe pain, with vomiting and purging. One case of its fatal action when used for procuring abortion was referred to me in 1845 ("Med. Gaz.," 36, p. 646). A woman may die undelivered, or the fœtus may be expelled dead, and the woman afterwards die from the irritant effects produced on the stomach and bowels.

The powdered leaves of this plant are frequently employed as a popular abortive; they are readily obtainable in gardens. They may be given in the form of infusion or decoction. The former is the most powerful. Savin may also be given as a tincture, or as an essential oil. In any of these forms, when given in large or frequently repeated doses, it has an irritant action. The powdered leaves are not used in medical practice. The dose as an emmenagogue would be from five to fifteen grains; the medicinal dose of the oil is from two to six minims, and of the tincture (*Tinctura Sabinæ*, B. P.) from twenty minims to one fluidrachm. This holds the oil and resin dissolved. The leaves of savin may be identified by their peculiar odor when rubbed, and also their appearance under the microscope. (See *ante*, p. 184.)

Cases in which the oil of savin has been administered for the purpose of abortion are not very common. In *Reg. v. Pascoe* (Cornwall Lent Assizes, 1852) a medical man was convicted and sentenced to transportation for administering oil of savin to a woman with intent to procure miscarriage. The proof of intent rested partly on medical, and partly on moral circumstances. It appears that the prisoner had given fourteen drops of the oil, divided into three doses, daily—a quantity which according to the medical evidence at the trial, was greater than should have been prescribed for any lawful purpose. The medicinal dose, as an emmenagogue, on the authority of Christison, is from two to five *minims*; and according to Pereira from two to six *drops*. The quantity given by the prisoner, although a full dose, was not, therefore, greater than these authorities recommend; and his criminality appears to have rested not so much on the doses given, as on the question whether he knew or, as a medical man, had reason to *suspect* that the woman for whom he prescribed it, was pregnant. No medical authority would recommend oil of savin in full doses for *pregnant* women; and with regard to the existence or non-existence of pregnancy in a special case, medical men are reasonably presumed to have better means of satisfying themselves than non-professional persons. The prisoner's innocence, therefore, rested on the presumption that he implicitly believed what the prosecutrix told him regarding her condition,—that he had no reason to *suspect* her pregnancy, and therefore did not hesitate to select and prescribe a medicine which certainly has an evil reputation, and is rarely used by regular practitioners. According to the evidence of the prosecutrix, she informed the prisoner that she had disease of the heart and liver, and that nothing more was the matter with her. It is absurd to suppose that oil of savin would be prescribed by a medical man for such a disease as this. The prisoner, on the hypothesis of innocence, must have intended that the medicine should act on the uterus, and must have inferred the existence of an obstruction to menstruation from natural causes irrespective of pregnancy. The jury do not appear to have given him credit for such

ignorance of his profession, and this probably led to his conviction. There can, it appears to me, be no doubt that the oil was administered with a guilty intention. Every qualified practitioner, acting *bond fide*, would undoubtedly satisfy himself that a young woman whose menses were obstructed, was *not pregnant*, before he prescribed full doses of this oil three times a day, or he would fairly lay himself open to a suspicion of criminality. If pregnancy—a frequent cause of obstructed menstruation—were only *suspected*, this would be sufficient to deter a practitioner of common prudence from prescribing, in any dose, a drug which may exert a serious action on the uterine system. (A report of the case of Mr. Pascoe will be found in the “Med. Times and Gazette,” April, 17, 1852, p. 104.) On the Northern Circuit, December, 1853 (*Reg. v. Moore*), a man was tried and convicted of administering oil of savin to a pregnant woman. It made her very ill, but did not produce abortion.

The *oil of savin* is obtained by the distillation of the tops, in the proportion of about 3 per cent. by weight. It has a yellowish color, and the peculiar terebinthinate odor of the plant, by which alone it may be recognized. It may be separated from the contents of the stomach by agitating them in a bottle with their volume of ether, in which the oil is very soluble. The ether may be afterwards removed by distillation. The odor of the oil is stated to have been perceived after death in the blood and in the cavities of the body. This may be regarded as the best test of its presence. (See a paper by Dr. Lex in Horn’s “Vierteljahrsschrift,” 1866, vol. 1, p. 241.) The oil of savin forms a turbid mixture with alcohol (.826). When treated with its volume of sulphuric acid, it acquires a dark brown color, and when this mixture is added to distilled water, a dense white precipitate is separated.

Tansy. Oil of tansy.—Dr. Hartshorne, an American physician, states that in the United States the *oil of tansy* has acquired the character of a popular abortive, and has caused death in several instances. In England this oil and the herb have been chiefly employed for the purpose of expelling worms. It has not hitherto been used as an abortive.

Dr. Jewett, of Fitchburg, U. S., describes the oil as one of the most dangerous of vegetable poisons in the United States. (“Boston Med. and Surg. Jour.,” No. 10, Feb. 1880, p. 237.) The oil has a greenish-yellow color, is lighter than water, and when kept for some time it deposits a species of camphor. It has the aromatic and peculiar pungent odor of the plant, and this, indeed, is one of the best tests of its presence. It has not hitherto been ranked among poisons in England, chiefly because there has been but little experience of its properties. In September, 1879, Dr. Jewett saw a patient who had shortly before taken this oil. He found her in a semi-conscious state—face, neck, and chest livid, as well as the fingers and finger-nails; eyes partly open, pupils widely and symmetrically dilated; pulse 120; the surface moist and cool; and there was an odor of tansy in the breath. It was subsequently found that she had first taken fifteen drops, and three hours afterwards a teaspoonful of the oil. In fifteen minutes she became generally convulsed, respiration was apparently suspended, and this was

followed by a complete and general cyanosis. She recovered in a day. Seven other cases of poisoning by this oil are related by Dr. Jewett. The symptoms were similar, and in four of these cases death took place—in one instance in little more than an hour after a teaspoonful of the oil had been taken. These recorded facts respecting oil of tansy show that it is a noxious substance within the meaning of the statute on abortion. They leave no room for hair-splitting, as in reference to cantharides and oil of juniper, in which it has been held that “quantity” is a necessary ingredient in the legal definition of the word “noxious.”

The *oil of juniper* and other essential oils have been used for the purpose of procuring abortion. They are all more or less irritant according to the dose administered, and must be regarded, in a medical point of view, as noxious substances.

Saffron, in the form of a decoction of the dried stigmas of saffron (*Crocus sativus*), has been used as a popular abortive. Dr. Thomsen, of Schleswig, has reported a case in which abortion occurred in a woman who had taken repeated doses of a decoction of saffron with starch. There was reason to believe, however, that manipulations *per vaginam* had also been resorted to, and these may have had the principal share in bringing about the result. (Horn's “Vierteljahrsschrift,” October, 1864, p. 315.) According to Pereira, although saffron was formerly used as an emmenagogue, and to promote uterine contractions, it is not established by any trustworthy observations that it possesses any medicinal properties. (“Mat. Med.,” vol. 2, pt. 1, p. 219.) In modern medicine its chief use is to give color and flavor to liquids.

Podophyllin.—This is a resinous substance extracted from the rhizome of the plant. It has a powerful action on the bowels, and may thus operate indirectly to expel the contents of the uterus. It was prescribed for a lady far advanced in pregnancy by a druggist. It caused severe griping pains and much straining (tenesmus); these symptoms were followed by miscarriage in eight days. In another case, of a woman about the sixth month of pregnancy, similar results followed from the use of podophyllin pills prescribed by a druggist. In one instance three-quarters of a grain in three doses caused severe colicky pains and tenesmus. (“Brit. Med. Jour.,” May, 1879, p. 773.)

According to Pereira, spurge laurel (*Daphne laureola*) has been used for the purpose of abortion. A farrier gave a girl, æt. 17, three pills for this purpose. They caused violent convulsions, under which she aborted, followed by coma and paralysis. She slowly recovered. This plant is an irritant. It produces violent vomiting, followed by inflammation of the stomach and bowels. (“Mat. Med.,” vol. 1, pt. 2, p. 481.)

Specific abortives. Echolics. Ergot of rye. Spurred rye (Secale cornutum).—The substance called *Ergot* is a diseased growth on the grain or seed of rye, caused by a parasitic fungus. In powder, infusion, or tincture, it has been for some time used by medical practitioners to excite the action of the uterus and aid parturition. It is also used for a similar purpose on animals in veterinary practice. The properties of ergot as an abortive are but little known to the vulgar in this country, and this may account for the fact of our rarely hearing of cases in which it has been criminally administered by midwives to pregnant

women. In a recent case it was proved that it had been supplied in large quantities to a midwife, and further, that the death of a pregnant woman from hemorrhage had been accelerated by the use of large doses of this drug. ("Pharm. Jour.," Dec. 28, 1878, p. 541.) A trial which took place at the Central Criminal Court in July, 1871, shows, also, that "herbalists" and "spiritualists" are well acquainted with the properties of ergot as an abortive; and are ready to supply it in secrecy (*Reg. v. De Baddeley and wife*). The prisoners in this case were indicted for unlawfully supplying a certain noxious drug—namely, ergot of rye, knowing that it was intended to procure abortion. They lived at Kennington, and an advertisement was inserted in a certain spiritualistic journal, inviting people to consult at that house "Madame De Baddeley, the celebrated clairvoyante." From what was alleged to be transacted there, the police were induced to send a woman named Hansard to consult the prisoners, and to concoct a story which might elicit their "spiritual" mode of procedure. After being put into a state of so-called "clairvoyance," the female prisoner advised the applicant what to do in the case of a young woman whom she had mentioned, and gave her a quantity of ergot of rye to procure abortion. In all, £6 was paid to the prisoners. The drug was at once handed over to the police. They were found guilty, and sentenced to twelve months' imprisonment.

The ergot of rye has been found to bring on contractions of the uterus at an advanced stage of gestation, or when efforts at parturition had already commenced. There is, however, some difference of opinion respecting its specific ecbotic properties. According to Dr. Lee, it has no effect in the *early* stages of gestation, although given in large doses. ("Med. Gaz.," vol. 25, p. 10; see also "Edin. Med. and Surg. Jour.," vol. 53, p. 27.) Dr. Kluge, of Berlin, found that its properties varied according to whether it was gathered before or after harvest; in the former case it had an energetic action, while in the latter it was powerless. Dr. Beatty states that when used in obstetric practice it is liable, by absorption into the system of the mother, which may take place within two hours, to endanger the life of the child. ("Dub. Med. Jour.," May, 1844, p. 202.) This question was actually referred by the French Government to the Academy of Medicine in 1845, as there was reason to think that, under its employment in the practice of midwifery, children were frequently born dead. ("Ann. d'Hyg.," 1846, 1, 204; see also "Med. Gaz.," vol. 46, p. 680.) In confirmation of Dr. Beatty's statement, Drs. McClintock and Hardy report that out of thirty cases in which it was administered, twenty children were born dead. ("Practical Observations," p. 95.) The late Dr. Ramsbotham considered that the drug might operate fatally on a child, according to the circumstances under which it was administered; but that, unless it excited the expulsive action of the uterus, it had no effect on the child's system. (Op. cit., p. 319; also cases by Mr. Paterson, "Edin. Med. and Surg. Jour.," vol. 53, p. 142.) According to M. Millet, in commenced or imminent parturition, ergot procures a safe and prompt termination; and he never met with a case in which it injured the child. ("Med.-Chir. Rev.," July, 1855, p. 41.) This is also the result of the more

recent experience of Dr. Uvedale West, contained in a paper read before the Obstetrical Society (July, 1861). Between December, 1855, and June, 1861, he had attended 734 labors, in 172 of which ergot was given. Including one case of twins, 173 children were born under the effects of ergot, of which number only five were stillborn. These facts appear to show that ergot, as a rule, does not exert those noxious effects on the child which have been attributed to it by some obstetric writers.

On trials for criminal abortion perpetrated or attempted, a medical witness must be prepared for a close examination on the ecboic properties of the ergot of rye on the uterus, as well as its general action as a poison on the woman and child. A case which occurred some years since (*Reg. v. Calder*, Exeter Lent Ass., 1844) has been reported, with comments on this subject by Dr. Shapter. ("Prov. Med. Jour.," April 10, 1844.) It was alleged on this occasion that savin, cantharides, and ergot had been respectively given by the prisoner, a medical man, for the purpose of procuring miscarriage. The prosecutrix, on whose evidence the case rested, was a woman of notoriously bad character, and the prisoner was acquitted. There were three medical witnesses, who agreed that savin and cantharides were only likely to occasion abortion indirectly, *i. e.*, by powerfully affecting the system—the view commonly entertained by professional men. Some difference of opinion existed with regard to *ergot*, but the balance of evidence was decidedly in favor of its specific action as a direct uterine excitant; and, according to Dr. Griffiths, this is so well known to the inhabitants of the United States, that it is there in frequent use as a popular abortive. In a case in which I was consulted in 1860, an attempt had been made to administer secretly the ethereal tincture of ergot.

A case occurred at Brighton in October, 1864, in which a question arose respecting the fatal effects of this drug on a woman who had taken it for a long period, obviously with a view to procure abortion. She died, however, without abortion having taken place; and the question at issue was, whether this drug had or had not caused her death. The dose taken was, I am informed, about a teaspoonful of the tincture of ergot three times a day, for a period of eleven weeks. On inspection, patches of inflammation were found on the mucous membrane of the stomach after death. No other cause for death was apparent, and one medical witness assigned it to the poisonous irritant action of the ergot, as, at the early stage of pregnancy which she had reached (the third month), this substance would not be likely to act as an abortive. Another medical gentlemen who gave evidence at the inquest, asserted that death could never be primarily caused by ergot of rye. The qualification introduced into this medical opinion is of small importance. The deceased woman is reported to have taken a large portion of the tincture, and it is quite immaterial whether the drug killed her by a primary or secondary operation. The late M. Tardieu describes the case of a woman, æt. 24, who aborted in the fourth month of pregnancy, as a result of the administration of ergot in powder; she died from peritonitis in about twenty-four hours. The ergot was found in fragments in the lower third of the bowels. ("Ann. d'Hyg.," 1855, vol. 1, p. 404.)

At the same time this medical jurist states that, in his opinion, ergot of rye has no direct action as an abortive ; in fact, that it is not an ecbo-lic. (“Ann. d’Hyg.,” 1865, 1, 139.) The numerous cases showing its efficacy, and its extensive use in midwifery practice, are sufficient to prove that this opinion is not borne out by facts. In respect to its operation, it may be observed that the effects produced by its administration are not such as readily to excite suspicion. It does not cause the decided symptoms of irritation observed in the action of savin, nor the nervous symptoms which are usually produced by rue. In medicinal doses, given at proper intervals, the only marked effect which it produces on a pregnant woman, is a lowering of the pulse. Sometimes other symptoms of a severe character have presented themselves. (“Ann. d’Hyg.,” 1856, 1, 140.) If a person dies from the effects of this drug, the results are legally the same, whether its operation as a noxious substance is of a primary or secondary kind.

Action of Ergot. Doses. Analysis.—In doses of from half a drachm to two drachms, ergot in powder has caused nausea, vomiting, dryness of the throat, great thirst, aversion from food, pain in the abdomen, slight purging, pain in the head, stupor, and dilatation of the pupils. (Pereira, “Mat. Med.,” vol. 2, pt. 1, p. 111.) The medicinal dose of the powder in uterine diseases, is from 5 to 15 grains. It is employed in a larger dose (from 20 to 60 grains at intervals of half an hour) to excite uterine action, either for abortion or parturition. The dose of the tincture is one drachm (a teaspoonful); this is considered to be equivalent to 20 grains of the powder. The dose of the ethereal tincture, according to Pereira, when employed for the purpose of exciting uterine action, is one drachm every half-hour, for three or four doses. (“Mat. Med.,” vol. 2, pt. 1, p. 118.) Ergot must be regarded as a noxious substance, and by some authorities it is ranked among narcotico-irritant poisons. Under the Sale of Poisons Act it is scheduled in the first class of poisonous substances, and can only be sold under certain restrictions, with the word Poison attached to it. It does not easily cause death in one large dose, but its fatal operation appears to be more strikingly developed by its long-continued use in small or medicinal doses. Its active properties have been ascribed to the presence of an oil or oleo-resin, soluble in ether. According to Herrmann, an ethereal solution distilled, yields a fixed oil of a brownish-yellow color, of aromatic odor and acid taste: it exerts no particular action, either as a medicine or as a poison. An alkaloid called *ecboline* has been discovered associated with the oil, and separable from it by a complex process (see “Pharm. Jour.,” Sept. 1871, p. 242); to this alkaloid, according to Wenzell, the medicinal action of ergot is due; others regard both ecboline and ergotine as inert. (“Med. Record,” Jan. 1873.) Ecboline is soluble in water, but only to a slight extent in alcohol, and the aqueous is considered to be more powerful than the alcoholic extract. The solid principle, called *ergotine*, to which its medicinal properties were formerly assigned, is described by Herrmann as a constituent of the red coloring matter contained in the dark purple outer coat.

The form and characters of the ergot in mass, are well known to pro-

fessional men. It consists of grains varying in length from half an inch to an inch and a quarter, and the breadth of about the eighth of an inch. The grain is cylindrical, blunt at the ends, and curved like the spur of a cock. The outer coat is of a dark purple color, almost black, irregularly fluted on the surface, which is often cracked and fissured. In the annexed illustration (Fig. 61), 1, 1, represent the ergot of rye as it is usually seen. The smaller of the two grains represent the average size; 2, 2, are sections of the grains, and 3 represents a transverse section magnified thirty diameters. The spongy character of the substance of the ergot is here more distinctly seen.

The ergot of rye.

The powder of ergot has a faint fishy smell; this is especially observed when it is rubbed with a solution of potash. This alkali dissolves it in part, and the solution acquires a dingy-red color. In the form of tincture, alcoholic or ethereal, the peculiar fishy odor of the extract when treated with potash is well marked. This is considered to be owing to the production of propylamine. It may, however, be concealed by other odors. Sometimes small particles of ergot, presenting a pink-red color in the dark external coat, may be detected in the sediment by the microscope. When ergot has been taken in powder, fragments of it may be found scattered over the lining-membrane of the stomach or bowels; these may be identified by the characters above described. The ethereal tincture of ergot, evaporated to an extract, yields a yellowish-colored oil, which, if any of the coloring matter of ergot is present, acquires a reddish color when heated with a solution of potash. On the chemical and microscopical properties of ergot, see a paper by Dr. Lex. (Horn's "Vierteljahrs.," 1866, 1, 231.)

It is not probable that a sufficient quantity of this substance will be found in the body of a person to whom it is alleged to have been given, to allow of the separation of *ecboline*. The medical jurist must rely upon the physical properties of the fungus, if he can obtain any of it. A spectral examination of the red alkaline solution of coloring matter presents nothing characteristic. The dry powder, heated in a reduction-tube, yields nitrogen as ammonia, and sulphur as sulphuretted hydrogen, discoverable by red litmus and lead-paper. Old samples smell strongly of ammonia, and often contain acari.

Local applications. Injections.—In a case which occurred in France, it was proved that abortion had been caused by the injection of some corrosive and irritating substance into the vagina. The genital organs, as well as the abdominal viscera, were found in a high state of inflammation. ("Med. Gaz.," vol. 37, p. 171.) This is an unusual mode of perpetrating the crime, but it is one which can hardly escape detection. An analysis of the tissues might be required, in order to determine the nature of the substance used. It appears from a trial which took place

at the York Summer Assizes, 1853, that this mode of attempting to procure criminal abortion, has been the subject of a prosecution in this country. It was established by the medical evidence that some liquid was injected into the vagina by a syringe, but there was no proof of the nature of this liquid; and as it was not shown to be of a *noxious* nature, the learned judge who tried the cause directed an acquittal. ("Lancet," July 23, 1853, p. 89.) It is proper to state, however, that the mere mechanical effect of an innocent liquid, frequently applied, may be more effectual in producing abortion or premature labor than the use of any irritating liquid. In medical practice, tepid water has been employed as an injection for the purpose of inducing premature labor in advanced pregnancy. Dr. Lazarewitch has published twelve cases in which the injection of water at 95° caused the uterus to contract and expel its contents. ("Trans. of the Obstetric Society," vol. 9, p. 161.) The earliest period at which Dr. Lazarewitch employed water, was in the thirtieth week of pregnancy. In most of the cases, the women have reached the thirty-sixth week of pregnancy. This is much later than the usual period at which abortion is commonly attempted for criminal purposes, namely, about the twenty-eighth week. Dr. Gallard has recently reported the case of a woman æt. 26, in whom abortion was produced by the simple injection of water between the third and fourth month of gestation. Savin and rue had been tried without effect. With the exception of a discharge of blood, the woman recovered without any untoward symptoms. ("Ann. d'Hyg.," 1879, 1, p. 358.) These cases prove that an innocent injection may be used to produce abortion, and, according to one judicial decision above given, the use of such a liquid would not render a person criminally liable. The words of the statute, however, "other means whatsoever," appear sufficiently comprehensive to include the use of a non-noxious liquid; and, according to a judicial opinion given in the case of *Wallis* (*Reg. v. Wallis*, p. 590), it is not material to prove that the liquid employed is of a "noxious" nature. In general, when the criminal means taken to procure abortion are effectual in causing the expulsion of the child, it comes into the world dead; but it may be born alive and die after its birth. Under these circumstances, although no violence is applied directly to the body of the child, but its death is simply the result of immaturity or the feeble state in which it was born, the person causing such abortion might render himself liable to an indictment for murder.

Signs of abortion in the living and dead.—These are practically the same as those elsewhere described as the signs of delivery. (See *ante*, pp. 556, 561.) The examination may extend to the woman either living or dead. In the former case there will be some difficulty, if the abortion has occurred at an early period of gestation and several days have elapsed before the examination is made; in the latter case, the investigation is not always free from difficulty. Dr. Shortt, of the Madras Presidency, who has had much experience on this subject, thus summarizes the symptoms which he has met with in numerous cases which came before him officially. In that Presidency alone there were 306 cases in two years, 1863-4. In the cases which he examined, up to a fortnight or a little later after the abortion, the vulva and passages were relaxed, the

mouth of the uterus patulous, and in the early stage there was a lochial secretion, replaced in later cases by a white mucous secretion, having the peculiar smell common to women in the puerperal state. Among other symptoms, were a distension of the breasts, a flow of milk on pressure, and a knotty feeling in them. There was a general anæmic or bloodless condition of the body, with sunken eyes, an excited pulse, and dry skin. In multiparous women the womb was more patulous, and the neck was not distinguishable; but in primiparous women the mouth of the uterus, although patulous to a small extent, still had the neck protuberant. ("Obstetric Transactions," vol. 9, p. 9.)

It is believed by many physiologists that menstruation is a state, in some measure vicarious to conception, and the appearances presented by the generative organs during the menstrual period are somewhat similar to those which are observed after conception in its early stage. Mr. Whitehead remarks that in women who died while the menses were flowing, the uterine walls were thickened and spongy, and the mucous lining was more or less swollen and suffused. The neck and lips of the uterus were swollen, the orifice was open, and the vaginal membrane and clitoris involved in the increased action. One of the ovaries was found larger and more congested than usual, presenting evidence of the recent escape of an ovum. (On "Abortion," p. 494; also p. 572, *ante*.) Unless these facts are attended to, an examiner may form an erroneous opinion respecting the chastity of a deceased woman. (For some remarks on the mode of conducting the examination of the woman, and of the embryo or foetus in cases of abortion, see "Ann d'Hyg.," 1856, 1, pp. 149, 153.)

Important questions may arise when it is alleged that abortion has been caused by the use of instruments, and death is referred to peritonitis, as the result of their employment. In these cases a medical opinion should not be based upon the statements either of the woman or of her friends, but upon some distinct and satisfactory medical proofs that mechanical violence has been done to the uterus, its contents, or its appendages. Peritonitis, or inflammation of the lining-membrane of the abdomen, may arise from a variety of causes. If we assign it to a particular cause, and thus implicate another in a felonious charge, we should do this only upon *medical* facts obtained by an examination of the dead body; we should deal with such cases as if we knew nothing of their previous history.

In September, 1871, a case occurred at Rotherham, in which a druggist was charged with using instruments to cause abortion, which had led to the death of a woman from peritonitis. It appeared also that he had given to her doses of the muriated tincture of iron. The woman was delivered of a dead foetus at about the fifth month, and she herself died shortly afterwards. There was nothing in the body of the woman or of the foetus to show that instruments had been used, but it was quite clear that peritonitis was the cause of death. One medical witness thought that an operation had been performed on the body of a woman, but it was admitted that peritonitis might arise from a variety of causes in a woman who had had a miscarriage. ("Pharm. Journ.," 1871, p. 256.) On the diagnosis of abortion and its causes, see a paper by Dr. Rudolph Lex (Horn's "Vierteljahrsschrift," 1866, 1, 179).

Feigned abortion.—For various motives, into the consideration of which it is unnecessary to enter, a woman may charge another with having attempted or perpetrated the crime of abortion. Such a charge is not common, because, if untrue, its falsity may be easily demonstrated. A young woman, admitted into Guy's Hospital in April, 1846, charged a policeman (who, according to her statement, had had forcible intercourse with her) with having given her some substance to produce abortion, and having subsequently effected this mechanically. She was not examined until nearly two months after the alleged perpetration of the crime, when the late Dr. Lever found that there was no reason to believe that she had ever been pregnant. This was a case of feigned abortion. When charges of this serious kind are brought forward, they are always open to the greatest suspicion, unless made immediately after the alleged attempt, as it is then only that an examination can determine whether they are true or false. If so long delayed as in this instance, without any satisfactory reason, the presumption is that they are false.

Legal relations.—[See "Revised Criminal Code of Pennsylvania," §§ 87, 88.—P.] In the statute for the consolidation of the criminal law (24 & 25 Vict., chap. 100, ss. 58 and 59), the nature of this crime, and the medical proofs required to establish it, have been more explicitly stated than in former Acts. By clause 58 (on attempts to procure abortion), it is enacted that "Every woman *being with child*, who, with intent to procure her own miscarriage, shall unlawfully administer to herself any poison or other noxious thing, or shall unlawfully use any instrument or other means whatsoever with like intent, and whosoever, with intent to procure the miscarriage of any woman, *whether she be or be not with child*, shall unlawfully administer, etc., shall be guilty of felony." The proposed new criminal code contains similar provisions regarding this crime, but it assigns a punishment of penal servitude for life, on any woman who is guilty of using means for procuring abortion on herself, and further, a punishment of penal servitude for five years on any one who unlawfully supplies or procures any poison or other noxious thing, or any instrument or thing whatsoever, knowing that the same is intended to be unlawfully used or employed with intent to procure the miscarriage of any woman, whether she be or be not with child, and whether she be or be not aware of such an intention.

As in every case a woman must be accessory to this crime upon herself, it leads to the difficulty that her evidence, uncorroborated by circumstances, may not be received by the court.

In two cases tried at the Lewes Summer Assizes, 1878, the woman charged with this crime was acquitted under the direction of the judge, because there was no corroboration of the evidence of the two women on whom the crime had been perpetrated. In one, the drugs prescribed by the prisoner produced no effect; she went her full time, and was delivered. In the other case, the woman was so ill that she could not appear as a witness, and it was admitted by counsel that he could not corroborate the evidence of either.

If such a rule and this is rigorously adhered to, and the jury, after due caution by the judges, are not allowed to form their own judgment of the credibility of the woman who is the victim of these nefarious

attempts, it will be easy for an abortionist to evade the law. As this is a crime of secrecy, and agent and patient are equally incriminated by the act, corroborating circumstances are not likely to be forthcoming on many of these occasions. On the other hand, false charges may be raised; but these would be easily detected by a cross-examination of the woman.

It will be observed that the *means* employed, whatever their nature, must have been used with an *intent* to procure the miscarriage of a woman—a point which will be sufficiently established by a plain medical statement of the means employed. Supposing that a drug has been used, the witness may be further required to state whether it is “a poison or other *noxious* thing.” I must refer the reader to what has been said elsewhere (*ante*, p. 81), in order that he may be able to judge how far the substance administered, would fall under the description above given. Whether the substance would or would not have the effect intended, *i. e.*, of inducing abortion, is perfectly immaterial.

Noxious substances.—Is it necessary to prove that the substance procured or administered is of a noxious nature? Some uncertainty may exist as to the strict meaning of the word *noxious*. All will allow that the word implies something injurious to the body; but a difference of opinion may arise among medical witnesses with respect to its application to the substance under discussion—as, for example, with respect to rue or savin. A substance must be regarded as injurious to the body, or noxious, either according to the form, quantity, or frequency with which it is administered. Savin, ergot, and rue are irritant; and they become noxious when given in large doses, or in small doses frequently repeated. (“Ann. d’Hyg.” 1838, 2, 180.) Aloes and castor-oil are innocent when taken in small doses; but they acquire noxious or injurious properties when administered frequently, or in large quantity, to a pregnant woman. To confine the term “noxious,” therefore, to what is strictly speaking a poison *per se*, would be giving a latitude to attempts at criminal abortion which would render the law inoperative. (See the case of *Reg. v. Stroud*, Abingdon Summer Assizes, 1846.) The small quantity of the substance taken at once does not affect the question, provided the dose be frequently repeated. A case in which I was consulted by Mr. Reynolds (a former pupil) was tried at the Exeter Winter Assizes, 1844. Two powders, weighing each one drachm, were prescribed by the prisoner: one consisted of colocynth, the other of gamboge, and with them was half an ounce of a liquid (balsam of copaiba). They were to be mixed together, and a fourth part to be taken four mornings following. Mr. Reynolds said, in answer to the question whether such a mixture was noxious or injurious, that each dose would be an active purgative, and might thereby tend to excite abortion. One dose would not be productive of mischief in a healthy countrywoman, but its frequent repetition might lead to serious consequences in a pregnant woman. In a trial which took place at the Norwich Lent Assizes, 1846 (*Reg. v. Whisker*), it was proved that the prisoner had caused to be taken by the prosecutrix a quantity of *white hellebore* in powder, for the purpose of procuring abortion. One medical witness said he considered hellebore to be noxious to the system, but he

knew of no case in which it had produced death; and under these circumstances he did not consider himself justified in calling it a poison. Another medical witness stated, in his opinion, it belonged to the class of poisons. The judge, in summing up, told the jury that *that* was to be regarded as a poisonous drug which, in common parlance, was generally understood and taken to be such; and he thought the medical evidence sufficiently strong to bring hellebore within the meaning of the statute. The jury found the prisoner guilty, alleging that in their belief white hellebore was a poison. ("Med. Gaz." vol. 37, p. 830.) The only circumstance calling for remark in this case is, that any doubt should have been entertained by a medical practitioner respecting the poisonous properties of *white hellebore*. It is a powerful vegetable irritant, and has caused death in several instances; yet on this occasion it appears to have been admitted to be *noxious*, but not *poisonous*.

Medical proof of the nature of the substance administered and that it was *noxious*, was formerly required on these occasions. In *Reg. v. Taylor* (Exeter Winter Assizes, 1859), some powders had been given by the prisoner to a girl with a view of inducing abortion. No portion of the powders could be obtained for examination; but two medical gentlemen who heard the evidence, deposed that in their opinion the powders were of a noxious nature. In the defence, it was urged that this had not been proved so by a chemical analysis. The jury adopted this view, and returned a verdict of acquittal. In *Reg. v. Wallis* (Winchester Autumn Assizes, 1871), (see p. 586, *ante*), Brett, J., in addressing the grand jury, is reported to have called their attention to the words of the statute, which declares that where any person shall unlawfully administer a poison or some other noxious thing, or shall unlawfully use any instrument or other means whatsoever, with intent to procure miscarriage, he shall be guilty of felony. The learned judge said that, having regard to the words "other means whatsoever," though there might be some doubt as to the construction of the statute, he should direct that in one count of the indictment the word "noxious" should be omitted, and he should hold that if the person accused did administer some drug or something which he thought would procure miscarriage with that intent, although the thing itself would not procure that miscarriage, he would nevertheless be guilty of the offence, and they ought to find a true bill.

According to this judicial direction, it would appear that it is not in all cases necessary to prove by medical evidence that the substance procured or administered was of a noxious nature. The words of the 59th clause, as to procuring a noxious thing, or any instrument or "thing whatsoever," strictly interpreted, would include all substances, noxious and innoxious. If this view is generally adopted in future cases, medical evidence will be much simplified. Counsel will not be under the necessity of severely cross-examining medical witnesses on the strict meaning of the word "noxious." In *Reg. v. Wallis* the substances procured by the accused were not noxious, but the jury acquitted him apparently on the ground that he did not actually administer the drugs: hence the question of noxiousness did not formally arise. From the ruling in this case, it would appear that if a person procured or administered castor-

oil or camphor julep, with intent to procure miscarriage, and with a belief that the substance would produce it, he would be found guilty of the offence. This being so, the use of the word poison and noxious thing in the statute is surplusage, and tends only to cause confusion in the medical evidence.

In *Reg. v. Newton* (Lewes Summer Ass., 1873), it was proved that the prisoner had given to a girl who was pregnant by him some pills and a powder, which made her very sick. A witness was called, who described himself as a laboring man, and stated that the prisoner obtained the medicine from him, that he had taken some of the pills himself, that they were antibilious pills, and that the powder was rhubarb. Under these circumstances, counsel for the defence submitted that there was no evidence that the medicine administered was "a noxious thing" within the meaning of the statute which created the offence, citing the case of *Reg. v. Isaacs*, 32 "Law Jour." M. C. Martin, B., however, overruled the objection, and the prisoner was found guilty, and sentenced to nine months' imprisonment with hard labor. A much stricter meaning is attached to the word "noxious" by learned judges when the substance has been given for procuring abortion, than where the intention has been to aggrieve or annoy, under the statute on poisoning. In the case of *Reg. v. Hennah* (Cornwall Lent Assizes, 1877), p. 81; cantharides was held *not* to be noxious unless administered in a *quantity* to produce injurious effects on the body, especially in a pregnant woman.

In a medical point of view, cantharides is not merely a noxious substance, but a powerful poison. It is described, and the sale of it is prohibited, as such, in the schedule of the act for regulating the sale of poisons (31 and 32 Vic., ch. 121). As in the case of prussic acid or strychnia, the dose may be such as to produce no effect on the body—or it may operate beneficially as a medicine, or destroy life as a poison. Small doses of the powder, *i. e.*, from a grain and a half to two grains, have, however, given rise to irritation of the bladder, strangury, and other serious symptoms ("British Med. Journal, 1877, p. 466), but in the case of *Hennah* (*supra*), in which about two grains had been given to a young woman apparently with the intention of exciting erotic feelings (p. 82), it was held by Cockburn, C. J., that this was not a noxious substance, within the meaning of the statute, and the prisoner was acquitted! This ruling has not been accepted by other judges. In *Reg. v. Cramp*, a case reserved from the Kent Winter Assizes, a question arose whether half an ounce of the oil of juniper given to a young woman with the intention to procure abortion, was a noxious substance within the meaning of the statute. (Crown Cases Reserved, Feb. 1880.) A portion of the oil had been taken and had caused sickness. It was held that it was noxious, and had been given with intent, so that the conviction was upheld. Three of the learned judges expressed an opinion that *any quantity* of a poison—that is an article known as a poison—administered with the intent charged, would be within the enactment. This is more consistent with common sense and medical doctrines than the ruling in the case of *Reg. v. Hennah*, which would render it lawful to administer experimentally any well-known poisons, provided some one

could be found to express an opinion that the quantity was too small to produce any effects.

In reference to the medical proofs of this crime, it is not required, under the circumstances, that any specific injury should have been done to the woman, or that abortion should have followed, in order to complete the offence. It is not even necessary to prove that she was with child, or that the aborted substance was a foetus or child. It might be a mass of blood, a mole or a group of hydatids. There is every reason to believe that the crime is frequent, but its perpetration is secret. Applications are frequently made to medical men and druggists by the lower class of people for drugs for this purpose; the applicants appear to have no idea of the criminality of the act. Under the name of "female pills" or "drops," medicines are thus dispensed in secrecy; and those who supply, as well as those who receive them, appear to have no idea that they are exposing themselves to a criminal prosecution. In one case a bottle containing a liquid supposed to have been used for the purpose of abortion, was sent to me for examination. It was labelled "Persian Otto of Roses." It contained a strong ethereal tincture of ergot of rye!

On a recent trial for criminal abortion, the medical evidence went far beyond its customary boundary. It appeared that the prisoners had applied to a medical man to supply them with drugs for procuring abortion. The medical man, mistaking his duty under such circumstances, gave information to the police, and acting under their advice supplied some drug which could do no injury. The prisoners were thus led to the commission of a felony, and at the trial the medical man appeared in the capacity of informer as well as expert, a circumstance which led to some severe observations from the judge. When such an application is made to a professional man there is no objection to the fact being made known to the police or magisterial authorities, but beyond this he should not go. He should refuse to supply the applicants with drugs, or lend himself in any way as a detective for the purpose of a prosecution. The act was no doubt done with a good intention to protect the public, but under a mistaken sense of duty. (See in reference to the frequency of this crime, a paper in the "Medical Gazette," vol. 46, p. 487; also "Med. Times and Gaz.," Nov. 21, 1857, pp. 524, 537.)

On inducing premature labor. Medical responsibility.—It may be proper to offer here a few remarks upon the common practice of inducing *premature labor*, in certain cases of disease, of deformity of the pelvis, and in cases of excessive vomiting from pregnancy. This practice has been condemned as immoral and illegal; but it is impossible to admit that there can be any immorality in performing an operation to give a chance of saving the life of a woman, when, by neglecting to perform it, it is almost certain that both herself and the child will perish. (See, on the morality, safety, and utility of the practice, Ramsbotham's "Obstet. Med.," p. 315.) Any question respecting its illegality cannot be entertained; for the means are administered or applied with the *bonâ fide* hope of benefiting the female, and not with any criminal design. It is true that the law makes no exception in favor of medical men who adopt this practice, nor does it in the Statute on Wounding make any exceptions in

favor of surgical operations ; but that which is performed *bond fide* would not be held to be unlawful. The necessity for the practice ought to be apparent: thus, for instance, it should be shown that delivery was not likely to take place naturally without seriously endangering the life of a woman. It is questionable whether, under any circumstances, it would be justifiable to bring on premature expulsion, merely for the purpose of attempting to save the life of a child, since the operation, even when performed with care, is accompanied with risk to the life of the mother. Hence a cautious selection of cases should be made, because the operation is necessarily attended with some risk to the woman and child. All that we can say is, that, according to general professional experience, it places the woman in a better position than she would be in, if the case were left to itself. It appears to me that before a practitioner resolves upon performing an operation of this kind he should hold a consultation with others ; and, before it is performed, he should feel assured that natural delivery cannot take place without greater risk to the life of the woman than the operation would itself create. These rules may not be observed by obstetric experts in large practice ; but the non-observance of them is necessarily attended with some responsibility to a general practitioner. In the event of the death of the woman or child he exposes himself to a prosecution for a criminal offence, from the imputation of which even an acquittal will not always clear him in the eyes of the public. If the child were born alive, and died merely as a result of its immaturity, this might give rise to a charge of manslaughter. Within a recent period several practitioners have been tried upon charges of criminal abortion—whether justly or unjustly it is not necessary to consider ; but they had obviously neglected to adopt those simple measures of prudence, the observance of which would have been at once an answer to a criminal charge. Because one obstetric practitioner of large experience may have frequently and successfully induced premature labor without observing these rules, and without any imputation on his character, this cannot shield another who may be less fortunately situated.

Chemical evidence. Blood in abortion. Liquor amnii.—In the event of an abortion having taken place, stains produced by blood or by the waters (*liquor amnii*) may be found on the linen of a woman, and a practitioner may be required to say whether these stains are of a nature to throw any light upon the perpetration of the crime. A woman who has aborted, may allege that the stains are those of the menstrual discharge. Speaking generally, there is no practical distinction between menstrual and other blood. (See *ante*, p. 302.) The menstrual blood contains less fibrin, is commonly acid and watery from admixture with the mucous discharges, and when examined by the microscope it presents epithelial scales, or cells derived from the mucous membrane. These scales or cells belong to the columnar variety. (See RAPE, *post.*) Not much reliance can be placed upon their discovery, since the mucous membrane of the organs of respiration is lined with similar cells. Hence expectorated blood might be mistaken for menstrual. Cells of a similar shape line the whole of the mucous membrane from the stomach to the anus. The blood of piles might thus be confounded with menstrual blood. The blood discharged in abortion will present the usual char-

acters of blood, elsewhere described (*ante*, pp. 295, 301); but it may be diluted with the waters simultaneously discharged. This question received the special attention of the French Academy a few years since, in reference to the crime of abortion; and the report made, was to the effect that in the present state of science there was no certain method by which the blood of menstruation could be practically distinguished from the blood discharged from a woman in a case of abortion, or from blood in infanticide. ("Ann. d'Hyg.," 1846, 1, 181.) In a more recent case, MM. Devergie and Chevallier were required to state whether certain stains on the dress of a woman supposed to have aborted, were or were not caused by the waters (*liquor amnii*). A chemical analysis merely revealed the presence of an albuminous liquid. The most elaborate experiments satisfied the reporters that neither by the odor nor by any other process could the *liquor amnii*, dried on linen, be identified. (See "Ann. d'Hyg.," 1852, 2, 414.) It may, however, be of importance to observe that this liquid slightly discolours and stiffens the fibre of the stuff on which it has been effused, and that it can be readily extracted by cold water. The solution possesses all the properties of albumen. The amount of albumen contained in the *liquor amnii* decreases as gestation advances. At the fourth month it forms 10.77 per cent. of the liquid; at the fifth month, 7.67; at the sixth month, 6.67; and at the ninth month, only 0.82 per cent. M. Chevallier's experiments show that the amniotic liquid has all the usual chemical properties of a very diluted solution of albumen. ("Ann. d'Hyg.," 1856, 1, 156.)

INFANTICIDE.

CHAPTER XLVII.

NATURE OF THE CRIME.—MEDICAL EVIDENCE AT INQUESTS.—UTERINE AGE OR MATURITY OF THE CHILD.—CHARACTERS OF THE CHILD FROM THE SIXTH TO THE NINTH MONTH.—SIGNS OF MATURITY.—RULES FOR INSPECTING THE BODY.

THE subject of child-murder has of late years attracted the attention of medical jurists by reason of the facility with which the crime may be perpetrated, and the great difficulty of bringing it home to the offender. The reports of inquests show that the deaths of infants are very numerous, and that they frequently occur under circumstances involving great suspicion. In his annual report for 1862–63, Dr. Lankester, coroner for the central division of Middlesex, states that there were 68 deaths of new-born children in his district, and in 53 of these, verdicts of wilful murder were returned against persons unknown; it appears, according to

this report, that the crime is more frequent amongst women in domestic service than in any other class. There is usually considerable reluctance on the part of a jury to return a verdict of wilful murder, when the mother has been discovered. In all instances, in which the evidence of guilt has been so clear that coroners' juries have found verdicts of wilful murder, the prisoners have been subsequently acquitted on their trials. Such is the history of cases in which the crime has been detected, and as the present state of the law offers every facility to a woman thus detected, to escape punishment, the extensive existence of the crime of infanticide will not excite surprise. ("Annual Report," 1864, p. 83.) In the report of the committee appointed to inquire on the best means of preventing the destruction of the lives of infants (July, 1871), it is stated that the number of infants found dead in the Metropolitan and City Police districts during the year 1870, was 276, and the return up to May 19, 1871, showed a total of 105. The greater number of these infants were less than a week old. From the statistics of crime in Ireland published in December, 1871, the same failure in the administration of the law is observed there. Infants form less than 3 per cent. of the population according to the census, but murders of infants are in England and Ireland considerably more numerous than murders of adults. In Ireland, according to Dr. Hancock, the latter are 37 times the number of murders occurring in the rest of the population; in England and Wales, 55 times. Out of 139 cases in which a coroner's jury found that infants had been murdered, arrests were made in 95 instances; but it is a striking proof of the strong feeling against capital punishment for infanticide that, though 42 persons were convicted of lesser offences, not one conviction for murder was obtained.

By infanticide, we are to understand in medical jurisprudence, the murder of a *new-born* child. The English law, however, does not regard child-murder as a specific crime; it is treated like any other case of murder, and is tried by those rules of evidence which are admitted in cases of felonious homicide. In stating that infanticide is the term applied to the murder of a *new-born* child, it is not thereby implied that the wilful killing should take place within any particular period after birth. Provided it be proved that the child has actually died from violence, it matters not whether it has been destroyed within a few minutes, or not until several days after its birth. According to a late return of the Registrar-General (for 1871), it appears that out of 202 murders 120 were perpetrated on children under one month. In the greater number of cases of infanticide, however, we find that the murder is commonly perpetrated either at the time of birth, or within a few hours afterwards. Although the law of England treats a case of infanticide as one of ordinary murder, yet there is a difference in the nature of the medical evidence required to establish the murder of a new-born child. It is well known that many children come into the world dead, and that others die from various causes soon after birth; in the latter, the signs of their having lived are frequently indistinct. Hence, to provide against the danger of erroneous accusations, the law humanely assumes that every new-born child has been born dead, until the contrary appears from the medical or other evidence. The onus of proof that a

living child has been destroyed is thereby thrown on the prosecution, and no evidence imputing murder can be received, unless it be first made certain, by medical or other facts, that the child survived its birth, and was *legally* a *living* child when the alleged violence was offered to it. Hence there is a most difficult duty cast upon a medical witness on these occasions. In the greater number of cases the woman is delivered in secrecy, and no one is present to give evidence respecting the birth of the child. It is under these circumstances that medical evidence is especially required. For reasons elsewhere assigned (see *ante*, p. 44) a medical man should be especially cautious in putting questions to a woman charged with this crime. In most instances, however, the body of the child is found, an inquest is held, and medical evidence is demanded.

Uterine age, or maturity of the child. Viability.—One of the first questions which a witness has to consider in a case of alleged child-murder, is that which relates to the age or probable degree of maturity which the deceased child may have attained in utero. The reason for making this inquiry is that the chances of natural death in all new-born children, are great in proportion to their immaturity; and that, supposing them to have survived birth, the signs of their having breathed are commonly obscure. It is found that the greater number of children who are the subjects of these investigations have reached the eighth or ninth month of gestation: yet charges of murder might be extended to the wilful destruction of children at the seventh month or under, provided the evidence of life after birth was clear and satisfactory.

The following are the characters whereby we may judge of the uterine age of a child from the *sixth* to the *ninth* month of gestation, a period which may be considered to comprise cases of abortion as well as child-murder:—

1. Between the *sixth* and *seventh* months: The child measures, from the vertex to the sole of the foot, from ten to twelve inches, and weighs from one to three pounds. The head is large in proportion to the trunk; the eyelids are adherent, and the pupils are closed by membranes (*membranæ pupillares*). The skin is of a reddish color, and the nails are slightly formed; the hair loses the silvery lustre which it previously possessed, and becomes darker. Ossification proceeds rapidly in the chest-bone, and in the bones of the foot; the brain continues smooth on its surface; there is no appearance of convolution. In the male the testicles will be found in the abdominal cavity, lying upon the *psoæ* muscles, immediately below the kidneys.

2. Between the *seventh* and *eighth* months: The child now measures between thirteen and fourteen inches in length, and weighs from three to four pounds. The skin is thick, of a more decidedly fibrous structure, and covered with a white unctuous matter which appears for the first time. Fat is deposited in the cellular tissue, whereby the body becomes round and plump; the skin previously to this is of a reddish color, and commonly more or less shrivelled; the nails, which are somewhat firm, do not quite reach to the extremities of the fingers; the hair is long, thick, and colored; ossification advances throughout the skeleton; *valvulæ conniventes* appear in the small intestines, and meconium is found occu-

pying the cæcum and colon. The testicles in the male about this period commence their descent,—or rather, the child's head being downwards, their ascent towards the scrotum. The time at which these organs change their situation is probably subject to variation. According to J. Hunter, the testicles are situated in the abdomen at the seventh, and in the scrotum at the ninth month. Burns believes that at the eighth month they will commonly be found in the inguinal canals. The observation of the position of these organs in a new-born male child is of considerable importance in relation to maturity, and it may have an influence on questions of legitimacy as well as of child-murder. Mr. Curling thus describes their change of position: At different periods between the fifth and sixth months of foetal existence, or sometimes even later, the testicle begins to move from its situation near the kidney towards the abdominal ring, which it usually reaches about the *seventh* month. During the eighth month it generally traverses the inguinal canal, and by the end of the ninth, arrives at the bottom of the scrotum, in which situation it is commonly found at birth. ("Diseases of the Testis," 2d ed., p. 17.) Its absence from the scrotum does not necessarily indicate that the child is immature, because the organ sometimes does not reach the scrotum until after birth.

3. Between the *eighth* and *ninth* months: The child is from fifteen to sixteen inches in length, and weighs from four to five pounds. The eyelids are no longer adherent, and the membranæ pupillares have disappeared. The quantity of fat deposited beneath the skin is increased, and the hair and nails are well developed. The surface of the brain is grooved or fissured, but presents no regular convolutions, and the cineritious matter is not yet apparent. The meconium occupies almost entirely the large intestines; and the gall-bladder contains some traces of a liquid resembling bile. The testicles in the male may be found occupying some part of the inguinal canal, or they may be in the scrotum. The left testicle is sometimes in the scrotum, while the right is situated about the external ring.

4. *Ninth month. Signs of maturity.*—At the ninth month the average length of the body is about eighteen inches, and its weight from six to seven pounds: the male child is generally rather longer, and weighs rather more than the female. Extraordinary deviations in length and weight are occasionally met with. Mr. Owens has recorded a case in which a child at delivery measured twenty-four inches in length, and weighed seventeen pounds twelve ounces ("Lancet," December, 1838), and Dr. Meadows has reported another in which a child measured, after death, thirty-two inches, and weighed eighteen pounds two ounces. It survived four hours. ("Med. Times and Gaz.," August 4, 1860.) In a case which I was required to examine in June, 1842, the child, a male, measured twenty-two inches, and weighed twelve pounds and a half. (For some practical remarks on this subject, by Dr. Ellsäßer, see Henke's Zeitschrift," 1841, vol. 2, p. 235.) According to Dr. Duncan, the length and weight of a child vary according to the age of the mother. They are greatest among children when the mother is from 25 to 29 years of age; but the facts collected do not support this statement; for the child of a woman at 22, weighed seven pounds three ounces, and

that of a woman of 30, seven pounds seven ounces. The length varied in a less degree, being for the different ages at or about nineteen inches. ("Ed. Mon. Jour.," Dec. 1864, p. 500.)

At the full period the head of a child is large, and forms nearly one-fourth of the whole length of the body. The cellular tissue is filled with fat, so as to give considerable plumpness to the whole form, while the limbs are firm, hard, and rounded; the skin is pale; the hair is thick, long, and somewhat abundant; the nails are fully developed, and reach to the ends of the fingers—an appearance, however, which may be sometimes simulated in a premature child by the shrinking of the skin after death. The testicles in the male are generally within the scrotum. Ossification will be found to have advanced considerably throughout the skeleton. The surface of the brain presents convolutions, and the cineritious or gray matter begins to show itself. The internal organs—principally those of the chest, undergo marked changes if the act of respiration has been performed by the child before, during, or after its birth.

The characters which have been here described as belonging to a child at the different stages of gestation must be regarded as representing an average statement. They are, it is well known, open to numerous exceptions; for some children at the ninth month are but little more developed than others at the seventh. Twins are generally smaller and less developed than single children:—the average weight of a twin child is not more than five pounds, and very often below this. The safest rule to follow in endeavoring to determine the uterine age of a child, is to rely upon a majority of the characters which it presents. That child only can be regarded as *mature* which presents the greater number of the characters described, that are met with in children at or about the ninth month of gestation.

If the age of the child has been determined—whether it be under or over the seventh month, the rules for a further investigation will be the same. Should the child be under the seventh month, the medical presumption will be that it was born dead; but if it has arrived at the full period, then the presumption is that it was born alive.

Conclusions.—The following may be taken as a summary of the principal facts upon which our opinion respecting the uterine age of a child may be based:—

1. At *six months*.—Length, from nine to ten inches; weight, one to two pounds; eyelids, agglutinated; pupils closed by membranæ pupillares; testicles not apparent in the male.

2. At *seven months*.—Length from thirteen to fourteen inches; weight, three to four pounds; eyelids not adherent; membranæ pupillares disappearing; nails imperfectly developed; testicles not apparent in the male.

3. At *eight months*.—Length, from fourteen to sixteen inches; weight, from four to five pounds; membranæ pupillares absent; nails perfectly developed, and reaching to the ends of the fingers; testicles in the inguinal canal.

4. At *nine months*.—Length, from sixteen to twenty-one inches; weight, from five to nine pounds; membranæ pupillares absent; head

well covered with fine hair; testicles in the scrotum; skin pale; the finger-nails well formed and reaching to the ends of the fingers; features perfect—these and the body are *well developed* even when the length and weight of the child are less than those above assigned.

5. The point of attachment of the umbilical cord, with respect to the length of the body, affords no certain evidence of the degree of maturity.

Inspection of the body.—The questions which a medical jurist has to solve, in examining the body of a new-born child, are: 1. To determine its age, or the stage of uterine life which it has reached; 2. Whether it has lived to breathe; 3. Whether it has been born alive; 4. The period of time which has elapsed since its death; 5. The cause of death, whether violent or natural.

Hence, before commencing the inspection—

1. The length (measured from the summit of the head to the sole of the foot) and weight of the body should be taken; 2. The presence or absence of external foetal peculiarities noticed; 3. Any peculiar marks or indications of deformity whereby identity may be sometimes established; 4. All marks of violence, in the shape of wounds, bruises, or lacerations, and the kind of instrument or weapon by which they were probably produced; 5. Whether the umbilical cord has been cut and tied, or lacerated: the appearance of the divided vessels, and the length of that portion which is still attached to the body of the child; 6. The presence or absence of vernix caseosa about the groins, armpits, or neck;—the presence of this substance proves that a child has not been washed or attended to; 7. It will be necessary to state whether there are about the body any marks of putrefaction, indicated by a separation of the cuticle, change of color in the skin, or offensive odor. It is obvious that unless these circumstances are noticed before the inspection is commenced, they may be entirely lost as evidence. Notes should be made on the spot, and the original retained, even if copies be subsequently made.

A medical man cannot be too careful in noticing upon the body of the child any special characters which may serve as proofs of identity. He must remember that the defence may be that the child is not that of the woman charged with murder. This observation applies especially to the examination of the bodies of children that may have survived their birth for some days. The body may be found wrapped in paper or in some article of clothing which may help to establish identity. If the child has survived its birth, it would be proper to form an opinion at once for how many days. The state of the umbilical cord, and whether the part of the abdomen to which it was attached is in the process of healing, or already healed, are facts which may help a medical opinion respecting the date of birth. (See “Ann. d’Hyg.,” Aout, 1879, p. 153.) In addition to these points, the sex of the child and the color of the hair should be noted, as well as any particular marks on the skin, *nævi* (mother’s marks), or moles, and, of course, all wounds or other injuries,—their probable cause or mode of production, and their situation.

CHAPTER XLVIII.

EVIDENCE OF LIFE BEFORE RESPIRATION.—PUTREFACTION IN UTERO.—
EVIDENCE OF LIFE AFTER RESPIRATION.—COLOR, VOLUME, CONSISTENCY,
AND ABSOLUTE WEIGHT OF THE LUNGS.—STATIC TEST.—WEIGHT IN-
CREASED BY RESPIRATION.

THE question whether a child was, or was not *born alive*, is of great importance in a case of alleged child-murder; and it is unfortunately one which, in respect to the proofs upon which medical evidence is commonly founded, has given rise to considerable controversy. When it is stated that in most cases of alleged infanticide which end in acquittals in spite of the strongest moral presumptions of guilt, the proof fails on this point only, it must be obvious that this question especially claims the attention of a medical jurist. The medical evidence of a child having been alive when violence was offered to it at its birth or afterwards, may be divided into two parts: 1, that which is obtainable before the act of respiration is performed; and 2, that which is obtainable afterwards. At present, it will be proper to confine our attention to the question, whether the child was legally *living* when it was maltreated;—the fact of its having been *born alive* will be a matter for future consideration. These two questions have been frequently but improperly associated, thus rendering the subject confused; but it must be so obvious as scarcely to require stating, that violence of a murderous kind may be offered to a living child *before* it is entirely born; and that owing to this violence it may come into the world dead.

Proofs of life before respiration.—It was formerly supposed, if the lungs contained no air, that the child could not have breathed, and must have been born dead; but this is now known to be an error. Children are able to breathe feebly, and continue in existence many hours without visibly distending the cells of the lungs with air;—the absence of air from the lungs, therefore, furnishes no proof either that respiration has not been performed, or that the child has not lived after birth. The restoration of many children apparently born dead is in itself a clear proof that many are born living who might be pronounced dead, simply because breathing and life have been erroneously considered as synonymous terms. That our law authorities will admit evidence of life in a child before the establishment of respiration, is clear from the decision in *Rex v. Brain*, in which the judge said, that a child might be born *alive*, and not breathe for some time after its birth (Archbold, “Crim. Plead.,” 367), as also from the charge of Coltman, J., in the case of *Rex v. Sellis* (Norf. Spr. Circ., 1837). In this instance it was alleged that the prisoner had murdered her child by cutting off its head. The judge directed the jury, that if the child was *alive* at the time of the

act, it was not necessary, in order to constitute murder, that it should have breathed. In fact, it would appear that respiration is regarded as only *one* proof of life; and the law will, therefore, receive any other kind of evidence which may satisfactorily show that a child has lived, and make up for the proof commonly derived from the state of the lungs.

In these cases it will be first necessary for a medical practitioner to prove that the child under examination has recently died, or, in other words, that there are good grounds for believing it to have been *recently living*. Hence, if the body is highly putrefied, either from the child having died in the uterus some time before birth, or from its having been born and its body not discovered until putrefaction had far advanced both internally and externally, the case is beyond the reach of evidence. A medical witness will in general be compelled to abandon the investigation, because the body can furnish no evidence whatever of life after birth. The examination of the thoracic organs would throw no light on the case, for here we are assuming that the lungs are in an unexpanded condition.

Evidence from marks of violence on the body.—It has been proposed to seek for evidence of life, under these circumstances, by observing the characters presented by marks of violence on the body. In general, when children are murdered, the amount of violence inflicted is considerably greater than that which is required to destroy them, whereby satisfactory proofs of the crime are occasionally obtained. On the other hand, the body of a still-born child, dead from natural causes, is often covered with lividities and ecchymoses;—the blood of the foetus or child does not coagulate with the same firmness as that of the adult: hence the evidence derivable from the extent, situation, and characters of marks of violence is often of too vague and uncertain a kind to allow of the expression of a medical opinion that the child was living when the violence was offered to it. The characters which have been already described as peculiar to wounds and contusions inflicted during life (pp. 260, 263), may be met with in the body, whether the child has breathed, or died without breathing. So again, these characters are open to the exceptions there pointed out; for they will be equally present, supposing the wounds to have been inflicted immediately after the cessation of respiration or circulation in the child, or after the cessation of circulation only,—if the act of respiration has not been performed. But marks of violence on the body of a child that had died in utero twenty-four or forty-eight hours before it was born, would not present the characters of injuries inflicted on a living child. There would be no ecchymosis and no effused coagula of blood. These marks, when they exist, although they may establish that a child was either living or but recently dead at the time they were inflicted, cannot show that it was *born* alive. Injuries met with on the bodies of children alleged to have been born dead ought, however, to be of such a nature as to be readily explicable on the supposition of their having arisen from accident. If, from their nature, extent, or situation, they are such as to evince a wilful or intentional design to injure, it is a fair ground for a jury (not for a medical witness) to inquire why these extensive wounds, or other marks of violence were inflicted on a child, if, as it is alleged, it was really born dead. It must

be confessed that in such a case there would be a strong moral presumption of murder, although medical proof of life or actually live birth, might totally fail.

As a summary of these remarks, it may be observed that although physiologically a child may live for a certain period after its birth without breathing,—and legally its destruction during this period would amount to murder,—yet there are at present no satisfactory medical data to enable a witness to express a positive opinion on this point in the majority of cases. If other evidence were adduced of a child having lived and been destroyed under these circumstances,—as where, for example, a woman causes herself to be delivered in a water-bath, or an accomplice covers the mouth of an infant in the act of birth or immediately after it is born,—a medical witness would be justified in asserting that the absence of the signs of respiration in the lungs was no proof that the child had been born dead. Indeed, it is apparent that breathing could not be established, owing to the criminal means actually employed to prevent it. The absence of air from the lungs may therefore really be the result of the forcible *prevention of respiration* during the act of birth. There cannot be the slightest medical doubt that living children are occasionally thus destroyed: they die, not from the actual infliction of violence, but because, either through design or accident, the performance of that act which is necessary to maintain existence when the child is born, is prevented. Whether an English jury would convict under these circumstances is doubtful; but this is of no importance to the witness:—his statements ought always to be made according to correct and well-ascertained medical principles, and not for the purpose of procuring either the conviction or acquittal of persons accused of crime. In general, those cases in which questions relative to life before respiration might arise, are stopped in the coroner's court,—the usual practice being, when the signs of respiration are absent or imperfect, to pronounce that the child was born *dead*. If the lungs sank in water, the presence of marks of violence on the body would be considered as furnishing no evidence, for the sinking of the lungs would in general be taken as a proof that the child was born dead, and that there could have been no murder.

This subject has been recently fully considered by Dr. Caussé (*Des preuves de la Vie en matière d'Infanticide*, "Ann. d'Hyg.," Nov. 1878, p. 471). After denouncing it as a great error to assert and act upon the principle that life and respiration are synonymous (*Vivre, c'est respirer*), he quotes many instances in which children have been born living, and survive birth for some time without breathing. It is during this period that an act of murder may be perpetrated, and satisfactory proofs of the crime may be frequently obtained by an examination of the body, irrespective of the condition of the lungs. In such children the heart continues to pulsate, and the circulation is carried on by the foramen ovale and the ductus arteriosus, as in the foetal state. The proof of this is seen in the fact that these children may be roused and made to breathe many minutes, and even a quarter of an hour, after birth. Dr. Caussé contends that if any ecchymosis is found on the skin of a new-born child, this is a proof that the blood was at the time circulating in the body of the child, and that it had been extravasated, as it would be from violence

applied to the living body. Such extravasations indicate the movement of blood towards the parts affected, and thereby furnish a proof of the existence of life at the time when the violence was inflicted. This proof would be strengthened in cases in which the blood was found coagulated, and the cellular membrane or fractured bones largely infiltrated. These are the essential characters of injuries inflicted on a living body, and they carry with them proofs of life from circulation as strongly as the presence of air in the lungs indicates life from respiration. The same remarks may be made respecting burns, attended with blisters containing serum or a line of redness (see page 408.) Assuming the child to have been born dead, these acts of violence could not have produced similar appearances on the body.

Dr. Caussé is supported by Devergie in considering respiration as only one sign of life, and that it may be absent in a child living for a quarter of an hour or longer after birth. The foetal circulation of the blood is equally a sign of life after birth, indicated by the marks of contusions, ecchymoses, and coagulation of the blood. In a case which occurred to Devergie, there were severe contusions with ecchymosis about the head of the child; the temporal muscles were deeply ecchymosed, and blood was infiltrated in the muscular fibres. The lungs, entire and divided, sank in water. They contained no air, and there was no evidence of breathing. The conclusions drawn by him were that this child had lived, and had been destroyed by violence to the head. The injuries were the result of violence applied during life, and could not have been produced on the body of the child while in the uterus. ("Ann. d'Hyg.," 1837, vol. 1, p. 407.)

In order to justify any inference respecting the life of a new-born child under these circumstances, the wounds or injuries should have those well-marked characters which have been elsewhere assigned to wounds on the living body (p. 260), and they should be of such a nature that they could not have been produced on the child by any accident when in the uterus.

There is a class of cases in which a child is born alive, but its lungs remain in the foetal condition, *i. e.*, they present no appearance of having received air by the act of breathing. These are cases of atelectasis (p. 609). The appearances in the body are the same as in still-born children. Professor Donders, who met with one of these cases in which he, in ignorance of the facts, pronounced a child to be still-born when it was distinctly proved that it had lived twelve hours, says, "Where the signs of an extra-uterine life, which does not betray itself by air in the lungs, are to be found, futurity must declare."

Proofs of life after respiration.—There is no doubt that the proof of the act of respiration furnishes the best and strongest evidence of a child having lived at or about the time it was born. It does not, however, show that a child has been *born alive*. The physical changes in the body of a child, which result from the establishment of this process, take place in the lungs immediately, and in the heart and its appendages more slowly. It is therefore chiefly to the *lungs* that a medical witness looks for proofs of respiration. Sometimes, however, these organs are found in their foetal condition, or nearly so: for although a child may have

survived its birth many hours, there may be no evidence of the fact from the state of the lungs. To such cases the remarks now about to be made cannot of course apply: the proofs of life must then be sought for elsewhere, and if none can be found, the case is beyond the reach of medical evidence. But it is obvious that the occasional occurrence of cases of this description can present no objection to our still seeking for proofs of life in the state of the lungs, any more than the fact of poison not being always discovered in the body of one who has died from poisoning, would be a bar to our seeking for the proofs of poison in any unknown case which presented itself. It is the more necessary to insist upon this point, because some have held that, as we cannot always derive proofs of life from an examination of the lungs of new-born children, we should abandon all evidence of this description, and leave the case in its original obscurity. The very object of medical jurisprudence is to endeavor to remove these difficulties, and to show in every department of the science the degree to which we may safely trust the medical proofs of crime, however insufficient, inconsistent, or contradictory they may at first sight appear.

Examination of the lungs.—The cavity of the chest may be conveniently laid open by carrying incisions from below the clavicles downwards on each side from about half the length of the ribs backwards. The diaphragm should be separated from the cartilages without opening the abdomen; the ribs sawn or cut through, and the flap formed by the front of the chest turned upwards. The differences in the relative position of the organs of the chest before and after respiration may be thus stated. 1. If a child has *not breathed*, the thymus gland, as large as the heart, will be found occupying the upper and middle portions of the chest;—the heart within its membrane (pericardium) is situated in the lower and middle portion, and is rather inclined to the left side. The lungs are placed quite in the back part of the chest, so as often to give the impression that they are wanting. In some instances they project slightly forwards by their anterior margins, but in no instance, unless congested, infiltrated, or otherwise diseased, do they cover and conceal the heart. The thymus gland is sometimes of a pale fawn—at others of a deep livid color; but there is no perceptible difference in this organ in new-born children, before or after the performance of respiration. 2. On the other hand, when a child has *fully breathed*, the most striking differences will be observed in the color and prominence of the lungs. They are of a light red hue, project forwards—appear to fill the entire cavity of the chest, and cover and in great part conceal, by their anterior margins, the heart and its membrane. We may meet with every variety in the appearances between these two extremes; for the process of respiration often requires a considerable time in order that it should be *fully* established, especially in children which are of a weakly constitution or prematurely born. Hence the lungs will be found to occupy their respective cavities to a greater or less extent, and to cover the pericardium more or less, not according to the length of time which a child has lived, but according to the perfection with which respiration has been performed. Although, as a general rule, the lungs are more perfectly filled with air in proportion to the time during which a child survives its birth, yet this

is open to numerous exceptions. The physical characters of the lungs now require notice.

Color.—The color of the lungs *before respiration* is bluish-red, or deep violet; but it is subject to variation. Some medical jurists have compared it to the color of the spleen. A short exposure to air will materially brighten the color in the parts exposed, so that it should be observed and recorded immediately on opening the chest. *After respiration*, the lungs acquire a light red hue in proportion to the degree in which the process has been performed. If imperfectly established, they will be mottled or marbled generally about the anterior surfaces and margins, the patches of light red being intermixed with the livid foetal hue, and being slightly raised, as if by distension, above the general surface of the organs. The light red tint changes, after a short exposure to air, to a bright scarlet.

Volume.—*Before respiration*, the lungs are in general scarcely visible, unless forcibly drawn forwards in the chest. When it has been perfectly accomplished, the volume is so much increased, that the bag of the heart (pericardium) is almost concealed by them. Respiration must, however, have been perfectly performed in order that this condition should exist to the full extent described.

Consistency.—The lungs, *before respiration*, feel like the liver, or any other of the soft organs of the body. They are firm under the finger, but their substance may be lacerated by violent compression. *After respiration* has been fully performed, there is a distinct sensation of what is termed crepitation, on compressing them, *i. e.*, air is felt within them. If a thin section of the lung is submitted to examination with a low power of the microscope,—*before respiration*, it will present the solid appearance of a section of the liver, spleen, or kidney—after respiration, air-cells will be distinctly seen in it. These conditions of the lungs must, of course, depend on the degree to which respiration has been carried. The lungs of children that have lived for a considerable time after birth, will sometimes give no feeling of crepitation under the finger. Generally speaking, lungs of this kind present the other foetal characters; thus they are small and of a livid color, and no air-cells may be detected on a microscopical examination.

Absolute weight of the lungs. The static test.—The absolute weight of the lungs before respiration, is less than that which they have after the establishment of the process. From this an inference has been drawn that the absolute weight of the lungs in an unknown case, compared with certain averages, will aid the inquirer in ascertaining whether respiration has or has not been performed. In order to determine the weight of the lungs, these organs should be carefully separated by dissection from the heart and thymus gland, and removed with the trachea and bronchi attached. Previously to their removal, ligatures should be placed on the pulmonary vessels, so that no blood may escape from the lungs. They should now be weighed, and the weight accurately noted in grains. The average weight *before respiration*, derived from nine cases, was found to be 649 grains. According to Dr. Traill, the weight varies from 430 to 600 grains. It is of importance in taking the weight of these organs to observe whether the child is at or near maturity, and whether

his body is fully developed, or of about *the average size and weight*: owing to a neglect of this rule, it is highly probable that comparisons have been made of the absolute weight of the lungs in children of different ages, which a full statement of the facts would not have justified. If it is small and immature, or unusually large, the lungs will weigh either less or more than the average. The average weight of the lungs, *after respiration*, derived from three cases, was 927 grains; but in making an estimate of this kind, much will depend upon the degree to which respiration has been carried. In three cases, in which the children lived half an hour, six hours, and twenty-four hours, respectively, the process had been so imperfectly performed, that the lungs varied but little in weight from the average before respiration. ("G. H. Rep.," No. V.) The truth is, we cannot compare the lungs of children, as to weight, by the *time* which they may have survived birth, but rather by the *degree* to which the lungs have been penetrated by air. Another circumstance must also be considered in basing an opinion on the absolute weight of the lungs. Although there does not appear to be any strict normal relation between the weights of the body and lungs in new-born children, yet it is certain that in the bodies of children of unusual weight, the lungs will be found much heavier than the average, whether the child has breathed or not. The body may vary from six to eighteen pounds; the lungs under these circumstances will also differ in weight.

The healthy lungs of mature new-born children become heavier after respiration, and according to its degree; and where a deviation from this rule is observed, it may probably be explained by the circumstance that the lungs of an immature have been compared with those of a mature child—the lungs of an undeveloped twin with those of one not a twin, or the lungs of one which has breathed imperfectly with those of another in which respiration has become well established. The following table represents the weight of the lungs, in four cases: it will show how much the organs are liable to vary in weight after birth, according to the *degree* of respiration:—

Case 1. Born dead	Weight, 687 grs.
2. Lived 6 hours	" 774
3. Lived 24 hours	" 675
4. Lived 9 days	" 861

Relying upon the mere weight of the lungs, it might be inferred from this table that the organs would weigh less in a child which had survived its birth twenty-four hours, than in another which had been born dead, and that there would be very little difference in the weight, whether the child lived six hours or nine days; but when it is stated that in Case 3 the lungs had every foetal character possessed by those in Case 1, and that in Case 4 respiration had been obviously very imperfectly performed, the difficulty is removed. Such cases should rather be compared with the lungs in the foetal than in the respired state. They merely show what is very well known to, and admitted by all medical jurists, that there are some instances in which the fact of respiration cannot be determined by the application of the static or any other test to the lungs, simply because they contain no air. Increased weight, therefore, is only one among several circumstances to which a medical jurist could attend.

Great weight of the lungs can obviously furnish no proof of respiration, unless this is accompanied by the other physical changes indicative of the process; as, for example, increase in volume from the presence of air, crepitation, and the detection of air-cells by the microscope. If the lungs are heavy, and at the same time contain little or no air, the increase of weight must depend upon disease or other abnormal causes—not upon respiration. In one case which I had to examine, the lungs were large, and weighed upwards of 1200 grains. They contained no air; when divided into thirty pieces, not one portion floated, nor could any air be seen on the closest examination. It was therefore clearly impossible to ascribe a weight so much above the average to the effects of respiration. On the other hand, in a case communicated to me by Mr. Cann, of Dawlish, the lungs of a new-born child apparently full-grown, although fully distended with air, weighed only 626 grains. In this case the body of the child weighed only six pounds, and a quantity of blood had, no doubt, escaped from the lungs, owing to the pulmonary vessels not having been tied before their removal from the chest. It must not be forgotten that all the physical characters presented by lungs that have respired are liable to certain fallacies; but, as in the evidence derived from tests used in poisoning, these may be removed, or the force of the objection diminished, by not basing an opinion on one or two conditions only. We should take the whole combined; for it would be as wrong to regard great weight in the lungs *taken alone* as an absolute proof of respiration, as it would be to draw the same inference from a mere change in the color, volume, or consistency of the organs.

M. Ploucquet proposed to determine whether the act of respiration had taken place or not, by a comparison of the absolute weight of the lungs with the weight of the body of a child. This, which has been called the *test of Ploucquet*, is based on the fallacy that there is an invariable relation between the weights of the lungs and bodies in new-born children. No such relation exists, and this method of arriving at a solution of the question of respiration, has been abandoned by all medical jurists.

The specific gravity of the lungs.—The specific gravity of the lungs is greater before than after respiration: for although the organs become absolutely heavier by the establishment of the process, this is owing, not to the air, but to the additional quantity of blood received into them. The air thus received, so increases the volume of the lungs as to more than counteract the additional weight derived from the blood, and thus apparently to diminish their specific gravity. Under these circumstances they readily float on water. From several experiments, I have found that the specific gravity of the lungs before respiration, *i. e.*, in the foetal condition, varies from 1.04 to 1.05. They are about one-twentieth part heavier than their bulk of water. After respiration, the specific gravity of the lungs with the air contained in them, I found in one experiment to be 0.94; *i. e.*, the organs were about one-seventeenth part lighter than their bulk of water. The introduction of a very small quantity of air will render the lungs buoyant in water; and an alteration in their volume sufficient for this purpose, would not be perceptible to the eye. It will be understood that the specific gravity of the substance of the lungs

is unchanged ; the organs are rendered only apparently lighter by the air contained in their cells, on the same principle as a bladder filled with air. Hence it follows that the apparent diminution of specific gravity will take place, whether the air is derived from respiration, artificial inflation or putrefaction. It is on this property of the lungs that the application of what is termed the *hydrostatic test*, or the *docimasia pulmonaris*, is founded—a subject which may be appropriately considered in another chapter.

Conclusions.—The general conclusions which may be drawn from the contents of this chapter are :—

1. That a child may be born alive and be criminally destroyed before it has breathed.

2. That the presence of any marks indicative of putrefaction while the child was in the uterus, proves that it must have come into the world dead.

3. That there are no certain medical signs by which a child that has not breathed can be proved to have been living when it was maltreated.

4. That a new-born child may be destroyed by the prevention of respiration during delivery.

5. That by taking together the color, volume, consistency, absolute weight, and buoyancy of the lungs, we may be able to draw an inference whether the child has or has not breathed.

6. That the lungs increase in weight according to the degree to which respiration is established, and not necessarily according to the period which the child has survived birth.

7. That no reliance can be placed upon the test of Ploucquet, or the proportionate weight of the lungs to the body.

CHAPTER XLIX.

THE HYDROSTATIC TEST.—SINKING OF THE LUNGS FROM DISEASE OR ATELECTASIS.—LIFE WITH PERFECT ATELECTASIS OR ENTIRE ABSENCE OF AIR FROM THE LUNGS.—ERRONEOUS MEDICAL INFERENCE FROM SINKING OF THE LUNGS.—FLOATING OF THE LUNGS FROM PUTREFACTION.—EFFECTS OF PUTREFACTION ON THE LUNGS.

The Hydrostatic test.—The mode of employing this test is extremely simple. Having removed the lungs from the chest, they should be placed, still connected with the air-tubes, upon the surface of distilled or river water. If they sink, it should be noted whether the sinking takes place rapidly or slowly. If they both sink, the two lungs should be tried separately ; for it is sometimes found that one, commonly the right, will float, while the other will sink. Supposing that both lungs sink, it will then be proper to divide each into twelve or fifteen pieces, and place these pieces separately on water. If after this they all sink, the inference is, that although the child may have lived and survived

its birth, *there is no evidence of its having breathed*. On the other hand, the organs when placed on water may float: it should then be noticed whether they float high above the surface, or at or below the level of the water; sometimes they indifferently float or sink. These differences will lead to a conclusion respecting the degree to which respiration has taken place. It will now be proper to separate the lungs and determine whether the buoyancy is due to one or both. Each lung should be divided as before, and each piece separately tried. If all the pieces float, even after firm compression, we have good evidence, *cæteris paribus*, that respiration has been very perfectly performed. Should any of the divided portions sink in water, either before or after compression, our opinion should be modified accordingly. Some have recommended that the lungs should be placed on water with the heart and thymus gland attached; but there appears to be no good reason for this, since it is as easy to form an opinion of the degree of buoyancy possessed by the lungs, from the readiness with which they float, as by observing whether or not they have the power to support these two organs.

With regard to the inference derivable from the use of this test, it should be observed that the floating of the lungs in water is not, as it is often incorrectly represented to be, a proof that a child has been *born alive*: nor is the fact of their sinking in water any proof that a child was *born dead*. The floating, under the limitations to be described, proves only that a child has *breathed*, the sinking, either that it has *not breathed*, or breathed but imperfectly. The fact of a child having been *born* living or dead, has, strictly speaking, no relation to the employment of the hydrostatic test. There are cases of infanticide which may be readily established without resorting to this test, and others which cannot be proved by its use: all that the law requires is proof that a child has been born living,—and whether this proof be furnished by the state of the lungs through the hydrostatic test, or in any other manner, is of no moment. The signs of life are commonly sought for in the lungs, because it is in these organs that the changes produced by a new state of existence are most distinctly perceived; but this examination may be dispensed with, when the woman confesses that the child was born alive—when others have seen it manifest life by motion or otherwise after its birth; or, lastly, in cases where, without being seen, it has been heard to cry. The crying of a child has been admitted as evidence of live birth on several trials for infanticide; although, as it is elsewhere stated, a child may utter a cry and die before its body is entirely born.

Among the *objections* which have been urged to the employment of the hydrostatic test, we have first to consider those which concern the sinking of the lungs in water.

Sinking of the lungs from disease, or atelectasis.—It is said that the hydrostatic test cannot show whether a child has or has not survived its birth, because the lungs of children that have lived for a considerable period, have been observed to sink entirely in water. In some instances this may depend on disease, tending to consolidate the air-cells, as *hepatization* or *scirrhus*—in others, on *œdema* or *congestion*: but these cases can create no difficulty, since the cause of the lungs sinking in water would be at once obvious on examination. The hepatized portion of

lung may be known by the firmness with which it resists cutting with a knife, as also by the fact that it is impossible to distend it artificially with air. On the other hand, there are cases in which the lungs appear healthy and unaffected: all that we can perceive is, that they retain their foetal condition. This is a very different state from that of hepatisation, because the lungs may in this unexpanded condition be made to receive air by artificial inflation. It is remarkable that life should continue for many hours, and sometimes even for days, under such a condition; but the occasional existence of this state of the lungs in a living child is placed beyond all dispute; the explanation of the causes upon which it depends—how it is that a child may live for hours or days, and no signs of respiration be discovered in its body after death—is, however, involved in difficulty. The lungs appear to be simply unexpanded, or to retain their foetal condition; a state to which the name of *atelectasis* has been given. This condition may be found to affect the whole, or a part of the organs.

Dr. Albert met with a case in which a child died *thirty-six hours* after its birth, having been attacked by convulsions at intervals during that time. On inspection, the whole of the right, and the lower portion of the left lung, were found to be in their foetal condition, and they immediately sank when immersed in water. There was no diseased appearance in the organs, and the undistended portions were easily filled by blowing air into them. (Henke's "Zeitschrift," 1837, vol. 2, p. 422.) M. Dépaul found, in many cases in which children had died suddenly after breathing for several hours or days, that the only unusual appearance in the body was an unexpanded condition of a large portion of the lungs. ("Med. Gaz.," vol. 39, p. 283.)

It is quite necessary for a medical jurist to be aware that the state of the lungs which is here called *atelectasis*, is by no means unfrequent among new-born children, although attention has been only of late years drawn to this subject. When no portion of air is found in the lungs of a child, there is no test by which such a case can be distinguished from one in which the child has come into the world dead. These cases of *atelectasis* are ordinarily set down as exceptions to a general rule: but I believe they are more common than some medical jurists are inclined to admit. In examining the body of a child, the history of which is unknown, it is proper that the possible occurrence of such cases should be well borne in mind. It appears to me not improbable, that many such come yearly before coroners in this country; and that they are dismissed as cases of still-born children, notwithstanding that marks of violence are often found upon the bodies. If, as it has been already observed, the lungs sink in water, this fact alone is commonly, although improperly, regarded as sufficient evidence of still-birth. This is assuredly putting the most humane interpretation on the circumstances, and so far the result is not to be objected to; but we should take care, in carrying out this principle, that we do not throw obstacles in the way of a subsequent judicial inquiry, and lead to the concealment of crime. Professor Bernt met with an instance in which a seven-months' child died *two hours* after birth; and when its lungs were divided and placed in water, every portion sank. Remer has reported another, in which the lungs sank in

water, both entire, as well as when divided, although the child had survived its birth at least *four days*. (Henke, "Lehrbuch der G. M.," p. 374.) In this case the navel-string had separated naturally before death. Orfila found in a child which had lived *eleven hours*, every portion of the lungs, when divided, to sink on immersion. In three other instances in which the children survived birth four, six, and ten hours, the lungs also sank when divided; two of these were mature. ("Med. Lég.," vol. 1, p. 375.) Other cases of a similar kind are reported by more recent writers. (See paper by Dr. Causse in "Ann. d'Hyg.," Nov. 1878, p. 489.)

Dr. Vernon attended a healthy woman, who was delivered of a child at about the *sixth month* of her pregnancy. The child was born before his arrival, and he heard it crying strongly from under the bed-clothes as he entered the room. After removal from the mother, the child cried at intervals, and it was observed that its chest rose and fell as in ordinary breathing. It lived five hours, and it then appeared to die from feebleness and exhaustion. It was a female child and very small; the body weighed 2 lbs. 13 ozs., and its length was 12 $\frac{3}{4}$ inches; the eyelids were adherent. The lungs were of a purplish-red color, and slightly overlapped the bag of the heart: they sank in water both entire and when divided into small pieces; they were not crepitant, and broke down under firm compression; there was no appearance of air-cells in a section of the lungs when examined by the microscope. The ductus arteriosus and foramen ovale were in their foetal state. ("Lancet," Feb. 3, 1855, p. 121.) A still more remarkable case occurred to Prof. Donders, of Utrecht. (Report by Dr. Moore, "Dublin Medical Press," Nov. 22, 1865, p. 456.) The body of the child was sixteen inches in length, and weighed nearly five pounds. It was probably a seven-months' child. The lungs were of a brown color, and sank in water entire and when divided. There was no crepitation, and on pressure only a reddish fluid without air escaped. The bladder was empty; there was no food in the stomach, but there was meconium in the larger intestine. From this state of facts Prof. Donders concluded that the child was immature—still-born—only a short time dead, and remaining in the uterus only a short time after death. It transpired, however, that the child had been born alive, had survived its birth twelve hours, and had cried distinctly after it was born. As the lungs could be readily inflated, and as the child had cried, he concluded that air had been received into the lungs, and had been again slowly expelled, the child dying in a kind of asphyxiated state.

Dr. Schwörer of Freiburg, delivered a woman in the hospital. The child did not breathe when born, but showed some signs of life. Thus the pulsations of the heart and umbilical cord were perceptible. These gradually ceased, and no effort could restore the child. On inspection, the lungs were found to contain no air; there was no crepitation when the substance of the lungs was cut and they sank in water, not only in the entire state, but when divided into numerous pieces. M. Poncet produced before the Lyons Medical Society (Oct. 1871) the lungs of a foetus, prematurely born at the Hôtel-Dieu. The child had cried, breathed, and lived an extra-uterine life for *ten hours*, but the lungs sank completely in water as if no respiration had taken place. ("Lancet,"

be confessed that in such a case there would be a strong moral presumption of murder, although medical proof of life or actually live birth, might totally fail.

As a summary of these remarks, it may be observed that although physiologically a child may live for a certain period after its birth without breathing,—and legally its destruction during this period would amount to murder,—yet there are at present no satisfactory medical data to enable a witness to express a positive opinion on this point in the majority of cases. If other evidence were adduced of a child having lived and been destroyed under these circumstances,—as where, for example, a woman causes herself to be delivered in a water-bath, or an accomplice covers the mouth of an infant in the act of birth or immediately after it is born,—a medical witness would be justified in asserting that the absence of the signs of respiration in the lungs was no proof that the child had been born dead. Indeed, it is apparent that breathing could not be established, owing to the criminal means actually employed to prevent it. The absence of air from the lungs may therefore really be the result of the forcible *prevention of respiration* during the act of birth. There cannot be the slightest medical doubt that living children are occasionally thus destroyed: they die, not from the actual infliction of violence, but because, either through design or accident, the performance of that act which is necessary to maintain existence when the child is born, is prevented. Whether an English jury would convict under these circumstances is doubtful; but this is of no importance to the witness:—his statements ought always to be made according to correct and well-ascertained medical principles, and not for the purpose of procuring either the conviction or acquittal of persons accused of crime. In general, those cases in which questions relative to life before respiration might arise, are stopped in the coroner's court,—the usual practice being, when the signs of respiration are absent or imperfect, to pronounce that the child was born *dead*. If the lungs sank in water, the presence of marks of violence on the body would be considered as furnishing no evidence, for the sinking of the lungs would in general be taken as a proof that the child was born dead, and that there could have been no murder.

This subject has been recently fully considered by Dr. Caussé (*Des preuves de la Vie en matière d'Infanticide*, "Ann. d'Hyg.," Nov. 1878, p. 471). After denouncing it as a great error to assert and act upon the principle that life and respiration are synonymous (*Vivre, c'est respirer*), he quotes many instances in which children have been born living, and survive birth for some time without breathing. It is during this period that an act of murder may be perpetrated, and satisfactory proofs of the crime may be frequently obtained by an examination of the body, irrespective of the condition of the lungs. In such children the heart continues to pulsate, and the circulation is carried on by the foramen ovale and the ductus arteriosus, as in the foetal state. The proof of this is seen in the fact that these children may be roused and made to breathe many minutes, and even a quarter of an hour, after birth. Dr. Caussé contends that if any ecchymosis is found on the skin of a new-born child, this is a proof that the blood was at the time circulating in the body of the child, and that it had been extravasated, as it would be from violence

applied to the living body. Such extravasations indicate the movement of blood towards the parts affected, and thereby furnish a proof of the existence of life at the time when the violence was inflicted. This proof would be strengthened in cases in which the blood was found coagulated, and the cellular membrane or fractured bones largely infiltrated. These are the essential characters of injuries inflicted on a living body, and they carry with them proofs of life from circulation as strongly as the presence of air in the lungs indicates life from respiration. The same remarks may be made respecting burns, attended with blisters containing serum or a line of redness (see page 408.) Assuming the child to have been born dead, these acts of violence could not have produced similar appearances on the body.

Dr. Caussé is supported by Devergie in considering respiration as only one sign of life, and that it may be absent in a child living for a quarter of an hour or longer after birth. The foetal circulation of the blood is equally a sign of life after birth, indicated by the marks of contusions, ecchymoses, and coagulation of the blood. In a case which occurred to Devergie, there were severe contusions with ecchymosis about the head of the child; the temporal muscles were deeply ecchymosed, and blood was infiltrated in the muscular fibres. The lungs, entire and divided, sank in water. They contained no air, and there was no evidence of breathing. The conclusions drawn by him were that this child had lived, and had been destroyed by violence to the head. The injuries were the result of violence applied during life, and could not have been produced on the body of the child while in the uterus. ("Ann. d'Hyg.," 1837, vol. 1, p. 407.)

In order to justify any inference respecting the life of a new-born child under these circumstances, the wounds or injuries should have those well-marked characters which have been elsewhere assigned to wounds on the living body (p. 260), and they should be of such a nature that they could not have been produced on the child by any accident when in the uterus.

There is a class of cases in which a child is born alive, but its lungs remain in the foetal condition, *i. e.*, they present no appearance of having received air by the act of breathing. These are cases of atelectasis (p. 609). The appearances in the body are the same as in still-born children. Professor Donders, who met with one of these cases in which he, in ignorance of the facts, pronounced a child to be still-born when it was distinctly proved that it had lived twelve hours, says, "Where the signs of an extra-uterine life, which does not betray itself by air in the lungs, are to be found, futurity must declare."

Proofs of life after respiration.—There is no doubt that the proof of the act of respiration furnishes the best and strongest evidence of a child having lived at or about the time it was born. It does not, however, show that a child has been *born alive*. The physical changes in the body of a child, which result from the establishment of this process, take place in the lungs immediately, and in the heart and its appendages more slowly. It is therefore chiefly to the *lungs* that a medical witness looks for proofs of respiration. Sometimes, however, these organs are found in their foetal condition, or nearly so: for although a child may have

survived its birth many hours, there may be no evidence of the fact from the state of the lungs. To such cases the remarks now about to be made cannot of course apply: the proofs of life must then be sought for elsewhere, and if none can be found, the case is beyond the reach of medical evidence. But it is obvious that the occasional occurrence of cases of this description can present no objection to our still seeking for proofs of life in the state of the lungs, any more than the fact of poison not being always discovered in the body of one who has died from poisoning, would be a bar to our seeking for the proofs of poison in any unknown case which presented itself. It is the more necessary to insist upon this point, because some have held that, as we cannot always derive proofs of life from an examination of the lungs of new-born children, we should abandon all evidence of this description, and leave the case in its original obscurity. The very object of medical jurisprudence is to endeavor to remove these difficulties, and to show in every department of the science the degree to which we may safely trust the medical proofs of crime, however insufficient, inconsistent, or contradictory they may at first sight appear.

Examination of the lungs.—The cavity of the chest may be conveniently laid open by carrying incisions from below the clavicles downwards on each side from about half the length of the ribs backwards. The diaphragm should be separated from the cartilages without opening the abdomen; the ribs sawn or cut through, and the flap formed by the front of the chest turned upwards. The differences in the relative position of the organs of the chest before and after respiration may be thus stated. 1. If a child has *not breathed*, the thymus gland, as large as the heart, will be found occupying the upper and middle portions of the chest:—the heart within its membrane (pericardium) is situated in the lower and middle portion, and is rather inclined to the left side. The lungs are placed quite in the back part of the chest, so as often to give the impression that they are wanting. In some instances they project slightly forwards by their anterior margins, but in no instance, unless congested, infiltrated, or otherwise diseased, do they cover and conceal the heart. The thymus gland is sometimes of a pale fawn—at others of a deep livid color; but there is no perceptible difference in this organ in new-born children, before or after the performance of respiration. 2. On the other hand, when a child has *fully breathed*, the most striking differences will be observed in the color and prominence of the lungs. They are of a light red hue, project forwards—appear to fill the entire cavity of the chest, and cover and in great part conceal, by their anterior margins, the heart and its membrane. We may meet with every variety in the appearances between these two extremes; for the process of respiration often requires a considerable time in order that it should be *fully* established, especially in children which are of a weakly constitution or prematurely born. Hence the lungs will be found to occupy their respective cavities to a greater or less extent, and to cover the pericardium more or less, not according to the length of time which a child has lived, but according to the perfection with which respiration has been performed. Although, as a general rule, the lungs are more perfectly filled with air in proportion to the time during which a child survives its birth, yet this

is open to numerous exceptions. The physical characters of the lungs now require notice.

Color.—The color of the lungs *before respiration* is bluish-red, or deep violet; but it is subject to variation. Some medical jurists have compared it to the color of the spleen. A short exposure to air will materially brighten the color in the parts exposed, so that it should be observed and recorded immediately on opening the chest. *After respiration*, the lungs acquire a light red hue in proportion to the degree in which the process has been performed. If imperfectly established, they will be mottled or marbled generally about the anterior surfaces and margins, the patches of light red being intermixed with the livid foetal hue, and being slightly raised, as if by distension, above the general surface of the organs. The light red tint changes, after a short exposure to air, to a bright scarlet.

Volume.—*Before respiration*, the lungs are in general scarcely visible, unless forcibly drawn forwards in the chest. When it has been perfectly accomplished, the volume is so much increased, that the bag of the heart (pericardium) is almost concealed by them. Respiration must, however, have been perfectly performed in order that this condition should exist to the full extent described.

Consistency.—The lungs, *before respiration*, feel like the liver, or any other of the soft organs of the body. They are firm under the finger, but their substance may be lacerated by violent compression. *After respiration* has been fully performed, there is a distinct sensation of what is termed crepitation, on compressing them, *i. e.*, air is felt within them. If a thin section of the lung is submitted to examination with a low power of the microscope,—*before respiration*, it will present the solid appearance of a section of the liver, spleen, or kidney—after respiration, air-cells will be distinctly seen in it. These conditions of the lungs must, of course, depend on the degree to which respiration has been carried. The lungs of children that have lived for a considerable time after birth, will sometimes give no feeling of crepitation under the finger. Generally speaking, lungs of this kind present the other foetal characters; thus they are small and of a livid color, and no air-cells may be detected on a microscopical examination.

Absolute weight of the lungs. The static test.—The absolute weight of the lungs *before respiration*, is less than that which they have after the establishment of the process. From this an inference has been drawn that the absolute weight of the lungs in an unknown case, compared with certain averages, will aid the inquirer in ascertaining whether respiration has or has not been performed. In order to determine the weight of the lungs, these organs should be carefully separated by dissection from the heart and thymus gland, and removed with the trachea and bronchi attached. Previously to their removal, ligatures should be placed on the pulmonary vessels, so that no blood may escape from the lungs. They should now be weighed, and the weight accurately noted in grains. The average weight *before respiration*, derived from nine cases, was found to be 640 grains. According to Dr. Traill, the weight varies from 430 to 600 grains. It is of importance in taking the weight of these organs to observe whether the child is at or near maturity, and whether

his body is fully developed, or of about *the average size and weight*: owing to a neglect of this rule, it is highly probable that comparisons have been made of the absolute weight of the lungs in children of different ages, which a full statement of the facts would not have justified. If it is small and immature, or unusually large, the lungs will weigh either less or more than the average. The average weight of the lungs, *after respiration*, derived from three cases, was 927 grains; but in making an estimate of this kind, much will depend upon the degree to which respiration has been carried. In three cases, in which the children lived half an hour, six hours, and twenty-four hours, respectively, the process had been so imperfectly performed, that the lungs varied but little in weight from the average before respiration. ("G. II. Rep.," No. V.) The truth is, we cannot compare the lungs of children, as to weight, by the *time* which they may have survived birth, but rather by the *degree* to which the lungs have been penetrated by air. Another circumstance must also be considered in basing an opinion on the absolute weight of the lungs. Although there does not appear to be any strict normal relation between the weights of the body and lungs in new-born children, yet it is certain that in the bodies of children of unusual weight, the lungs will be found much heavier than the average, whether the child has breathed or not. The body may vary from six to eighteen pounds; the lungs under these circumstances will also differ in weight.

The healthy lungs of mature new-born children become heavier after respiration, and according to its degree; and where a deviation from this rule is observed, it may probably be explained by the circumstance that the lungs of an immature have been compared with those of a mature child—the lungs of an undeveloped twin with those of one not a twin, or the lungs of one which has breathed imperfectly with those of another in which respiration has become well established. The following table represents the weight of the lungs, in four cases: it will show how much the organs are liable to vary in weight after birth, according to the *degree* of respiration:—

Case 1. Born dead	Weight, 687 grs.
2. Lived 6 hours	" 774
3. Lived 24 hours	" 675
4. Lived 9 days	" 861

Relying upon the mere weight of the lungs, it might be inferred from this table that the organs would weigh less in a child which had survived its birth twenty-four hours, than in another which had been born dead, and that there would be very little difference in the weight, whether the child lived six hours or nine days; but when it is stated that in Case 3 the lungs had every foetal character possessed by those in Case 1, and that in Case 4 respiration had been obviously very imperfectly performed, the difficulty is removed. Such cases should rather be compared with the lungs in the foetal than in the respired state. They merely show what is very well known to, and admitted by all medical jurists, that there are some instances in which the fact of respiration cannot be determined by the application of the static or any other test to the lungs, simply because they contain no air. Increased weight, therefore, is only one among several circumstances to which a medical jurist could attend.

Great weight of the lungs can obviously furnish no proof of respiration, unless this is accompanied by the other physical changes indicative of the process; as, for example, increase in volume from the presence of air, crepitation, and the detection of air-cells by the microscope. If the lungs are heavy, and at the same time contain little or no air, the increase of weight must depend upon disease or other abnormal causes—not upon respiration. In one case which I had to examine, the lungs were large, and weighed upwards of 1200 grains. They contained no air; when divided into thirty pieces, not one portion floated, nor could any air be seen on the closest examination. It was therefore clearly impossible to ascribe a weight so much above the average to the effects of respiration. On the other hand, in a case communicated to me by Mr. Cann, of Dawlish, the lungs of a new-born child apparently full-grown, although fully distended with air, weighed only 626 grains. In this case the body of the child weighed only six pounds, and a quantity of blood had, no doubt, escaped from the lungs, owing to the pulmonary vessels not having been tied before their removal from the chest. It must not be forgotten that all the physical characters presented by lungs that have respired are liable to certain fallacies; but, as in the evidence derived from tests used in poisoning, these may be removed, or the force of the objection diminished, by not basing an opinion on one or two conditions only. We should take the whole combined; for it would be as wrong to regard great weight in the lungs *taken alone* as an absolute proof of respiration, as it would be to draw the same inference from a mere change in the color, volume, or consistency of the organs.

M. Ploucquet proposed to determine whether the act of respiration had taken place or not, by a comparison of the absolute weight of the lungs with the weight of the body of a child. This, which has been called the *test of Ploucquet*, is based on the fallacy that there is an invariable relation between the weights of the lungs and bodies in new-born children. No such relation exists, and this method of arriving at a solution of the question of respiration, has been abandoned by all medical jurists.

The specific gravity of the lungs.—The specific gravity of the lungs is greater before than after respiration: for although the organs become absolutely heavier by the establishment of the process, this is owing, not to the air, but to the additional quantity of blood received into them. The air thus received, so increases the volume of the lungs as to more than counteract the additional weight derived from the blood, and thus apparently to diminish their specific gravity. Under these circumstances they readily float on water. From several experiments, I have found that the specific gravity of the lungs before respiration, *i. e.*, in the foetal condition, varies from 1.04 to 1.05. They are about one-twentieth part heavier than their bulk of water. After respiration, the specific gravity of the lungs with the air contained in them, I found in one experiment to be 0.94; *i. e.*, the organs were about one-seventeenth part lighter than their bulk of water. The introduction of a very small quantity of air will render the lungs buoyant in water; and an alteration in their volume sufficient for this purpose, would not be perceptible to the eye. It will be understood that the specific gravity of the substance of the lungs

is unchanged ; the organs are rendered only apparently lighter by the air contained in their cells, on the same principle as a bladder filled with air. Hence it follows that the apparent diminution of specific gravity will take place, whether the air is derived from respiration, artificial inflation or putrefaction. It is on this property of the lungs that the application of what is termed the *hydrostatic test*, or the *docimasia pulmonaris*, is founded—a subject which may be appropriately considered in another chapter.

Conclusions.—The general conclusions which may be drawn from the contents of this chapter are :—

1. That a child may be born alive and be criminally destroyed before it has breathed.

2. That the presence of any marks indicative of putrefaction while the child was in the uterus, proves that it must have come into the world dead.

3. That there are no certain medical signs by which a child that has not breathed can be proved to have been living when it was maltreated.

4. That a new-born child may be destroyed by the prevention of respiration during delivery.

5. That by taking together the color, volume, consistency, absolute weight, and buoyancy of the lungs, we may be able to draw an inference whether the child has or has not breathed.

6. That the lungs increase in weight according to the degree to which respiration is established, and not necessarily according to the period which the child has survived birth.

7. That no reliance can be placed upon the test of Ploucquet, or the proportionate weight of the lungs to the body.

CHAPTER XLIX.

THE HYDROSTATIC TEST.—SINKING OF THE LUNGS FROM DISEASE OR ATELECTASIS.—LIFE WITH PERFECT ATELECTASIS OR ENTIRE ABSENCE OF AIR FROM THE LUNGS.—ERRONEOUS MEDICAL INFERENCE FROM SINKING OF THE LUNGS.—FLOATING OF THE LUNGS FROM PUTREFACTION.—EFFECTS OF PUTREFACTION ON THE LUNGS.

The Hydrostatic test.—The mode of employing this test is extremely simple. Having removed the lungs from the chest, they should be placed, still connected with the air-tubes, upon the surface of distilled or river water. If they sink, it should be noted whether the sinking takes place rapidly or slowly. If they both sink, the two lungs should be tried separately ; for it is sometimes found that one, commonly the right, will float, while the other will sink. Supposing that both lungs sink, it will then be proper to divide each into twelve or fifteen pieces, and place these pieces separately on water. If after this they all sink, the inference is, that although the child may have lived and survived

its birth, *there is no evidence of its having breathed*. On the other hand, the organs when placed on water may float: it should then be noticed whether they float high above the surface, or at or below the level of the water; sometimes they indifferently float or sink. These differences will lead to a conclusion respecting the degree to which respiration has taken place. It will now be proper to separate the lungs and determine whether the buoyancy is due to one or both. Each lung should be divided as before, and each piece separately tried. If all the pieces float, even after firm compression, we have good evidence, *cæteris paribus*, that respiration has been very perfectly performed. Should any of the divided portions sink in water, either before or after compression, our opinion should be modified accordingly. Some have recommended that the lungs should be placed on water with the heart and thymus gland attached; but there appears to be no good reason for this, since it is as easy to form an opinion of the degree of buoyancy possessed by the lungs, from the readiness with which they float, as by observing whether or not they have the power to support these two organs.

With regard to the inference derivable from the use of this test, it should be observed that the floating of the lungs in water is not, as it is often incorrectly represented to be, a proof that a child has been *born alive*: nor is the fact of their sinking in water any proof that a child was *born dead*. The floating, under the limitations to be described, proves only that a child has *breathed*, the sinking, either that it has *not breathed*, or breathed but imperfectly. The fact of a child having been *born* living or dead, has, strictly speaking, no relation to the employment of the hydrostatic test. There are cases of infanticide which may be readily established without resorting to this test, and others which cannot be proved by its use: all that the law requires is proof that a child has been born living,—and whether this proof be furnished by the state of the lungs through the hydrostatic test, or in any other manner, is of no moment. The signs of life are commonly sought for in the lungs, because it is in these organs that the changes produced by a new state of existence are most distinctly perceived; but this examination may be dispensed with, when the woman confesses that the child was born alive—when others have seen it manifest life by motion or otherwise after its birth; or, lastly, in cases where, without being seen, it has been heard to cry. The crying of a child has been admitted as evidence of live birth on several trials for infanticide; although, as it is elsewhere stated, a child may utter a cry and die before its body is entirely born.

Among the *objections* which have been urged to the employment of the hydrostatic test, we have first to consider those which concern the sinking of the lungs in water.

Sinking of the lungs from disease, or atelectasis.—It is said that the hydrostatic test cannot show whether a child has or has not survived its birth, because the lungs of children that have lived for a considerable period, have been observed to sink entirely in water. In some instances this may depend on disease, tending to consolidate the air-cells, as *hepatization* or *scirrhus*—in others, on *œdema* or *congestion*: but these cases can create no difficulty, since the cause of the lungs sinking in water would be at once obvious on examination. The hepatized portion of

lung may be known by the firmness with which it resists cutting with a knife, as also by the fact that it is impossible to distend it artificially with air. On the other hand, there are cases in which the lungs appear healthy and unaffected; all that we can perceive is, that they retain their foetal condition. This is a very different state from that of hepatisation, because the lungs may in this unexpanded condition be made to receive air by artificial inflation. It is remarkable that life should continue for many hours, and sometimes even for days, under such a condition; but the occasional existence of this state of the lungs in a living child is placed beyond all dispute; the explanation of the causes upon which it depends—how it is that a child may live for hours or days, and no signs of respiration be discovered in its body after death—is, however, involved in difficulty. The lungs appear to be simply unexpanded, or to retain their foetal condition; a state to which the name of *atelectasis* has been given. This condition may be found to affect the whole, or a part of the organs.

Dr. Albert met with a case in which a child died *thirty-six hours* after its birth, having been attacked by convulsions at intervals during that time. On inspection, the whole of the right, and the lower portion of the left lung, were found to be in their foetal condition, and they immediately sank when immersed in water. There was no diseased appearance in the organs, and the undistended portions were easily filled by blowing air into them. (Henke's "Zeitschrift," 1837, vol. 2, p. 422.) M. Dépaül found, in many cases in which children had died suddenly after breathing for several hours or days, that the only unusual appearance in the body was an unexpanded condition of a large portion of the lungs. ("Med. Gaz.," vol. 39, p. 283.)

It is quite necessary for a medical jurist to be aware that the state of the lungs which is here called *atelectasis*, is by no means unfrequent among new-born children, although attention has been only of late years drawn to this subject. When no portion of air is found in the lungs of a child, there is no test by which such a case can be distinguished from one in which the child has come into the world dead. These cases of *atelectasis* are ordinarily set down as exceptions to a general rule: but I believe they are more common than some medical jurists are inclined to admit. In examining the body of a child, the history of which is unknown, it is proper that the possible occurrence of such cases should be well borne in mind. It appears to me not improbable, that many such come yearly before coroners in this country; and that they are dismissed as cases of still-born children, notwithstanding that marks of violence are often found upon the bodies. If, as it has been already observed, the lungs sink in water, this fact alone is commonly, although improperly, regarded as sufficient evidence of still-birth. This is assuredly putting the most humane interpretation on the circumstances, and so far the result is not to be objected to; but we should take care, in carrying out this principle, that we do not throw obstacles in the way of a subsequent judicial inquiry, and lead to the concealment of crime. Professor Bernt met with an instance in which a seven-months' child died *two hours* after birth; and when its lungs were divided and placed in water, every portion sank. Remer has reported another, in which the lungs sank in

water, both entire, as well as when divided, although the child had survived its birth at least *four days*. (Henke, "Lehrbuch der G. M.," p. 374.) In this case the navel-string had separated naturally before death. Orfila found in a child which had lived *eleven hours*, every portion of the lungs, when divided, to sink on immersion. In three other instances in which the children survived birth four, six, and ten hours, the lungs also sank when divided; two of these were mature. ("Med. Lég.," vol. 1, p. 375.) Other cases of a similar kind are reported by more recent writers. (See paper by Dr. Causse in "Ann. d'Hyg.," Nov. 1878, p. 489.)

Dr. Vernon attended a healthy woman, who was delivered of a child at about the *sixth month* of her pregnancy. The child was born before his arrival, and he heard it crying strongly from under the bed-clothes as he entered the room. After removal from the mother, the child cried at intervals, and it was observed that its chest rose and fell as in ordinary breathing. It lived five hours, and it then appeared to die from feebleness and exhaustion. It was a female child and very small; the body weighed 2 lbs. 13 ozs., and its length was $12\frac{3}{4}$ inches; the eyelids were adherent. The lungs were of a purplish-red color, and slightly overlapped the bag of the heart: they sank in water both entire and when divided into small pieces; they were not crepitant, and broke down under firm compression; there was no appearance of air-cells in a section of the lungs when examined by the microscope. The ductus arteriosus and foramen ovale were in their foetal state. ("Lancet," Feb. 3, 1855, p. 121.) A still more remarkable case occurred to Prof. Donders, of Utrecht. (Report by Dr. Moore, "Dublin Medical Press," Nov. 22, 1865, p. 456.) The body of the child was sixteen inches in length, and weighed nearly five pounds. It was probably a seven-months' child. The lungs were of a brown color, and sank in water entire and when divided. There was no crepitation, and on pressure only a reddish fluid without air escaped. The bladder was empty; there was no food in the stomach, but there was meconium in the larger intestine. From this state of facts Prof. Donders concluded that the child was immature—still-born—only a short time dead, and remaining in the uterus only a short time after death. It transpired, however, that the child had been born alive, had survived its birth twelve hours, and had cried distinctly after it was born. As the lungs could be readily inflated, and as the child had cried, he concluded that air had been received into the lungs, and had been again slowly expelled, the child dying in a kind of asphyxiated state.

Dr. Schwörer of Freiburg, delivered a woman in the hospital. The child did not breathe when born, but showed some signs of life. Thus the pulsations of the heart and umbilical cord were perceptible. These gradually ceased, and no effort could restore the child. On inspection, the lungs were found to contain no air; there was no crepitation when the substance of the lungs was cut and they sank in water, not only in the entire state, but when divided into numerous pieces. M. Poncet produced before the Lyons Medical Society (Oct. 1871) the lungs of a foetus, prematurely born at the Hôtel-Dieu. The child had cried, breathed, and lived an extra-uterine life for *ten hours*, but the lungs sank completely in water as if no respiration had taken place. ("Lancet,"

1872, 1, 227.) I may add to these instances two which have occurred under my observation. In one, the case of a mature male child, the lungs sank in water although the child had survived birth for a period of *six hours*. In the other, the case of a female twin, the child survived *twenty-four hours*; and after death the lungs were divided into thirty pieces; but not a single piece floated; showing therefore that, although life had been thus protracted, not one-thirtieth part of the structure of the lungs had received, by respiration, sufficient air to render it buoyant. ("Guy's Hospital Reports," No. 5, p. 355.) In the latter instance no particular remark was made during life respecting the breathing of the child.

These cases show most clearly that buoyancy of the lungs is not a necessary consequence of a child having lived and breathed for some time after birth. Probably, had they called for medico-legal inquiry, the lungs would have been cut to pieces: the sinking of the divided pieces in water, either before or after compression, would have been set down as negating the act of respiration, and unless other strong evidence had been forthcoming, it would have been asserted that the children had been born dead. Here, again, we perceive the necessity of not hastily assuming that a child has been *born dead*, because its lungs *sink* in water. There may be no good medical evidence of such a child having lived after birth, but assuredly the mere sinking of these organs does not warrant the common and positive dictum, that the child was necessarily dead when born; it would be as reasonable to pronounce, in a question of poisoning, that the fact of an individual having died from poison, was negated by the non-discovery of a poisonous substance in his stomach.

It must be apparent, on reflection, that cases of this description are beyond the reach of the hydrostatic as well as of all other tests applied to the respiratory organs; because the lungs do not receive and retain a sufficient quantity of air to give buoyancy after death, although the children may have lived some hours. The hydrostatic test is no more capable of showing that such children as these have lived, than it is of indicating from what cause they had died. Facts of this kind demonstrate that a passive existence may be for some time maintained under a state of the respiratory process not to be discovered after death. In the opinion of some, these cases form a serious objection to the hydrostatic test; but it is difficult to understand how they can affect its general application—or why, because signs of respiration do not always exist in the lungs of children that have lived, we are not to rely upon them when they are actually found. These exceptional instances prove that we are greatly in want of some fact to indicate life after birth, *when the signs of respiration are absent*. Until we discover this we must, of course, make the best use of that knowledge which lies at our disposal; taking care to apply it to those cases alone to which experience shows it to be safely adapted. In the mean time, the common inference that a child has been born dead because its lungs sink in water, is never likely to implicate an innocent party; it can only operate by sometimes leading to the liberation of the guilty.

It has been recommended that medical jurists should consider as *dead* every child that has not breathed, *i. e.*, *whose lungs sink in water*; but

they who give this advice, at the same time admit that children may come into the world living without breathing, and the law holds, under the decision of its expounders, that respiration is only *one*, and not an exclusive proof of life. In order to establish life or even live birth, respiration need not always be proved, either in civil or criminal cases (p. 600). A medical jurist would, therefore, be no more justified in asserting that all such children were necessarily born dead, than that they were born living; and in stating what is the plain and obvious truth, it is not possible that this statement can ever be the means of involving an innocent person. It is certain, however, in departing from the truth, and stating what is contrary to well-known facts, that when the lungs of a child sink in water, it is safe and just to consider such child as having been born *dead*, he is incurring the risk of exculpating a really guilty person; for it cannot be too strongly borne in mind, that a woman is not now charged with murder, merely because the lungs of her child float in water, but because there are upon its body marks of violent injuries apparently sufficient to account for its death, or there are strong moral presumptions of her guilt. (See "Ann. d'Hyg.," 1836, 2, 362.) But there is another aspect in which this question should be viewed. There may be no marks of murderous violence on the body of the child, nor any proofs of ill-treatment, yet a child born under these circumstances may have died through the culpable neglect or reckless indifference of the woman. Dr. Moore, of Dublin, in reporting two cases of atelectasis, in one of which a child had survived its birth twelve hours, remarks that when such a child is deserted or exposed, without the necessary attention required for its helpless state, the conditions are precisely fulfilled to cause its death within a few hours under a diminution of temperature and a total expulsion of air from the lungs. He has no doubt that many a child so found, which had met with its death through want of care, is looked upon as not having lived. ("The Medical Press," Nov. 22, 1865, p. 458.) It will be seen hereafter that some of our judges have recently given a strong exposition of the law, so as to bring cases of this description within the crime of manslaughter.

Floating of the lungs from other causes than respiration.—Another series of objections has been urged to the hydrostatic test, based on the fact that the lungs may receive air and acquire buoyancy from other causes than respiration. These causes are two: putrefaction and artificial inflation. *Putrefaction.*—The lungs of a still-born child, when allowed to remain in the chest, are slow in undergoing putrefaction; but nevertheless, they sooner or later acquire sufficient air to render them buoyant in water. When the lungs are putrefied, this will be determined, in general, by putrefaction having extended throughout all the soft parts of the body. The organs, according to the degree of putrefaction, will be found soft, of a dark green or brown color, and of a highly offensive odor; the serous membrane covering the surface will be raised in large visible bladders, from which the air may be forced out by very moderate compression. It has been remarked that, under the same conditions, gaseous putrefaction takes place as rapidly in the liver, heart, and thymus gland of a new-born child, as in the lungs; we should, therefore, notice the general state of the body. The distension of the lungs with gas

from putrefaction cannot be easily overlooked or mistaken for the air of respiration. The answer to any objection founded on the putrefied state of these organs must at once suggest itself. It is impossible that any well-informed medical witness can expect to obtain satisfactory evidence from experiments on lungs in such a condition. He should abandon the case, and declare that in regard to the question of respiration, medical evidence cannot establish either the affirmative or the negative. The fact of his not being able to give the evidence required, cannot be imputed as a matter of blame to him, or ascribed to any deficiencies in the hydrostatic test; this is due to purely exceptional circumstances.

In a case reported by Henke, the lungs and other organs in the body of a child were found in an advanced state of putrefaction. A medical witness gave an opinion that the child was born dead, but the prisoner afterwards confessed that it had been born living. The medical opinion could have been no more than a conjecture, the condition of the body not allowing any correct conclusion to be drawn. This fact shows that it is always better to leave a doubtful case as we find it, than to express a positive opinion that the child has been born either living or dead. If on these occasions a witness were simply to assure a jury that medical evidence could not solve the question whether the child had lived or not—if he were to assert, what is really the fact, that his experiments would not allow him to say whether the child had or had not breathed—it is certain that no innocent person would ever be convicted or a guilty person acquitted upon his evidence. It is for a jury only to judge of guilt from *all* the circumstances laid before them; but it is assuredly not for a medical witness to prevent further investigation, and put an end to the case, when there is good reason for doubt. It is his duty to state that doubt, and leave the decision of guilt or innocence in the hands of the court.

Conclusions.—The general conclusions which may be drawn respecting the application of the hydrostatic test in cases of infanticide are the following:—

1. That the hydrostatic test can show whether a child has or has not breathed,—it does not enable us to determine whether a child has been born living or dead.

2. That the lungs of children that have lived after birth may *sink* in water, owing to their not having received air, or to their being in a diseased condition.

3. That a child may live for some time when only a small portion of the lungs has been penetrated by air.

4. That a child may survive birth even for twenty-four hours, when no part of its lungs has been penetrated by air.

5. Hence the sinking of the lungs (whether whole or divided) in water is not a proof that a child has been *born dead*.

6. That the lungs of children which have not breathed, and have been born dead, may float on water from putrefaction.

7. That the lungs as situated in the chest, undergo putrefaction very slowly,—that if but slightly putrefied, the gases may be easily forced out by compression, and if much putrefied, either the case must be abandoned, or other sources of evidence sought for.

CHAPTER L.

FLOATING OF THE LUNGS FROM ARTIFICIAL INFLATION.—INFLATION NOT DISTINGUISHABLE FROM IMPERFECT RESPIRATION.—RESULTS OF COMPRESSION.—IMPROPER OBJECTIONS TO THE HYDROSTATIC TEST.—RESPIRATION BEFORE BIRTH.—RESPIRATION A SIGN OF LIFE, NOT OF LIVE BIRTH.—GENERAL CONCLUSION.

Artificial inflation.—It has been alleged that the lungs of a still-born child may be made to assume by artificial inflation, *i. e.*, by blowing air into them, all the characters assigned to those which have undergone respiration. Thus, it is said, a child may not have breathed, and yet the application of the hydrostatic test would in such a case lead to the inference that it had. It will be seen that the force of this objection goes to attack directly the inference derivable from the discovery of air in the lungs. There is only one form under which this can be admitted as an objection, namely, as it applies to lungs which have been inflated while *lying in the cavity of the chest*. Any experiments performed on them after their removal from this cavity, can have no practical bearing, since in a case of infanticide we have to consider only the degree to which the lungs may be distended with air by a person who is fairly endeavoring to resuscitate a still-born child. Assuming that the experiment has been successfully performed, and that the lungs have been artificially inflated, they would resemble, in their partial distension with air and other physical characters, those of children which had breathed imperfectly. Like them, they may float on water; but on cutting them into pieces some of these would be found to sink. If the pieces which float are firmly compressed either by means of a folded cloth or between the fingers, they will lose air and sink. When this pressure is produced under water, it will be seen that bubbles of air escape, but mere pressure with the fingers will not in general suffice to expel the whole. The same result is obtained when the divided portions of lungs which have breathed imperfectly are submitted to pressure. If, however, the act of breathing has been perfectly performed, and the air-cells are well filled, the air cannot be expelled by pressure, or by any force short of the destruction of the substance of the lungs. This difference in the effect of pressure has been hitherto regarded as a criterion to distinguish lungs that have fully breathed from those which have been simply inflated; but Dr. Hicks met with a case which shows that pressure will not always effect the expulsion of air, artificially introduced into the lungs of a child born dead: hence by an exclusive reliance on this method, a medical man might be led to infer that a lung artificially inflated had received air by respiration. Dr. Hicks delivered a woman of a full-grown child; it was still-born, and there was no effort at respiration. An attempt was made

to resuscitate the child, but unsuccessfully, by blowing air into the lungs through a catheter. On inspection, the lungs were observed to be of large size, but they did not present the usual appearance of lungs which had breathed. Although about three-fourths of the organs had received air by inflation, they were of a pale fawn color, like the thymus gland; still the air was contained in the minute air-cells. They floated on water as well as all the pieces (fifteen or sixteen) into which they were divided. When compressed between the fingers under water, small bubbles of air escaped: but no amount of compression short of destroying their structure caused these pieces to sink. A fact of this kind, although perhaps exceptional, shows that the non-expulsion of air from lungs by compression, must not be regarded as an absolute proof of respiration. It must be taken with other circumstances, *e. g.*, absolute weight and color, as a fact to show that the child has either breathed, or has had its lungs perfectly inflated in a *bonâ fide* attempt to restore life after birth, either by the mother or by some person present at the birth. In these cases the only course left open to a medical witness, is to state that the evidence derived from experiments on the lungs left it uncertain whether the child in question had breathed, or had had its lungs artificially inflated. A jury will then know how to return their verdict: for it must be remembered, they have always circumstances, as well as medical opinions, to guide their judgment; and it is upon the *whole*, and not upon a part of the evidence laid before them that their verdict is founded.

In concluding these remarks upon the objections to the hydrostatic test, it may be observed that medical practitioners have differed much at different times in their ideas of what it was fitted to prove. About seventy years ago, it would seem that the test was regarded by some as capable of furnishing evidence of murder! Thus we find Dr. Hunter asking the question, "How far may we conclude that the child was born alive, and *probably murdered by its mother*, if the lungs swim in water?" Later authorities, and, indeed, many in the present day, assert that the test is capable of proving whether a child has been *born alive* or not! From what has already been stated, as well as from the most simple reflection on the circumstances accompanying the birth of a child, I think it must be evident that the hydrostatic test is no more capable of showing whether a child has been *born alive or dead*, than it is of proving whether it has been murdered or has died from natural causes. The majority of those who have made experiments on this subject have only pretended to show, by the use of this and other tests, whether or not a child has *breathed*,—the tests merely serve to furnish in many cases good proof of life from the state of the lungs; and slight reflection will render it apparent that in no case are they susceptible of doing more. Even here their utility is much restricted by numerous counteracting circumstances, a knowledge of which is essential to him who wishes to make a practical application of them. (See "Edin. Med. and Surg. Jour.," vol. 26, p. 365.)

If asked to state in what cases the pulmonary tests are capable of assisting a medical jurist, the answer, it appears to me, would be:—1st. They will clearly show that a new-born child has lived, when, during its life, it has *fully and perfectly breathed*. Cases of this description form

a certain number of those which come before our Courts of Assize. To them the most serious objections are not applicable ; and the few which might be made to the medical inferences are not difficult to answer. 2dly. They will allow a witness to say, that the lungs must have received air either by respiration or by artificial inflation. These are the cases in which a child has died soon after birth, and where the respiratory changes are but imperfectly manifested in the lungs. They probably form a large proportion of those which fall under the jurisdiction of the criminal law. It might be considered that the qualification in the inference here drawn would neutralize its force ; but it must be remembered that there are few instances of actual and deliberate child-murder wherein artificial inflation could become even a possible defence for an accused person. So unusual is this kind of defence, that among the numerous trials for infanticide which have taken place in this country for many years past, I have not been able to meet with a single instance in which it was alleged as an objection to the medical evidence derived from the buoyancy of the lungs, that the prisoner had inflated them in order to resuscitate her child. The reason is obvious ; had such a defence been attempted, the whole of the circumstantial evidence would at once have set it aside. When, in the suspected murder of an adult, a medical man swears that a fatal wound was such that the deceased might have inflicted it on himself, or that the prisoner might have produced it, he is placing the jury in a position very similar to that in which he places them in a case of child-murder, when he says that the child might have breathed, or its lungs might have been artificially inflated. How would a jury decide in the two cases ? Assuredly, by connecting certain facts with which a medical witness is not concerned, but which may, in their opinion, satisfactorily supply the place of what is deficient in his evidence. It is not for him to speculate on the probabilities of respiration, or of artificial inflation ; but it is for them to consider whether the accused was or was not likely, under the particular circumstances of the case, to have resorted to an experiment of this nature. It has been suggested that some person might inflate the lungs of a dead child, in order to raise a charge of murder against its mother ; but this suggestion presupposes, on the part of the criminal, a profound knowledge of the difficulties of medical jurisprudence ; and even then the question of *murder* does not depend merely on the presence of air in the lungs. Such a case is very unlikely to present itself ; indeed, its occurrence is no more probable than that in poisoning it should be considered a good defence that some person might have introduced poison into the body by injections after death. The circumstances of the case will commonly furnish a sufficient answer to such hypothetical views.

The hydrostatic test ought not, therefore, to be lightly condemned or rejected upon a speculative objection, which, in nine-tenths of the cases of child-murder, could not possibly exist. Let it be granted to the fullest extent that a conscientious medical jurist cannot always draw a positive distinction between the effects of respiration and artificial inflation on the lungs ; still a jury may be in a situation to relieve him from this difficulty. In short, it would be as reasonable to contend that all persons charged with murder should be acquitted, because homicidal are

not always to be distinguished from suicidal wounds, as to argue that all cases of infanticide should be abandoned because these two conditions are not distinguishable by any certain medical signs. If juries do frequently dismiss such cases, it is, I apprehend, to be ascribed rather to their great unwillingness to become the means of administering what they consider to be severe laws, than to their want of power to balance and decide on the probabilities laid before them. If the pulmonary tests were wholly set aside, it is easy to conceive what would be the consequences. Let us suppose that a new-born child is found under suspicious circumstances, with its throat cut; we are called upon to admit that it is impossible for medical evidence to establish whether the child has lived or not, and therefore we are to decline making an inspection of its body. But this would be the same as declaring that child-murder could never be proved against an accused party, and that new-born children might henceforth be destroyed with impunity! It appears to me that conduct of this kind, on the part of a medical witness, would be wholly unwarrantable; for we may sometimes acquire, by an inspection, as great a certainty of respiration having been performed, and therefore of a child having lived, as of any other fact of a medico-legal nature. Cases of poisoning often give rise to greater difficulties to a medical jurist; as where, for example, he attempts to found his opinion of the cause of death on symptoms alone, or on appearances in the dead body. But we may put the question in this light: In the body of a healthy full-grown child, which has but recently died, we find the lungs filling the cavity of the chest, of a light red color, spongy, crepitant beneath the finger, weighing at least two ounces, and when divided into numerous pieces, each piece floating on water, even after strong compression. Is it possible in such a case to doubt that respiration has been performed? If there is no certainty here, it appears to me that medical experience is but little fitted in any case to guide us in our inquiries. It would be difficult to point out an instance in which an affirmative medical opinion would be more surely warranted by the data upon which it was founded.

So far as I know there is only one recent instance in which a medical man declined to make an inspection of the body of a new-born child for the purpose of examining the state of the lungs. (*Reg. v. Pitt*, Dorset Summer Ass., 1859.) The body was found much mutilated, and with such injuries as would fully have accounted for the death of the child, assuming it to have been born alive. At the inquest the coroner suggested that a post-mortem examination should be made; but the chief medical witness declined to make it, as he did not consider it to be necessary. He was then asked by the coroner whether the floating of the lungs would indicate that the child had breathed, to which he replied that *that* theory was now exploded! It seems that the death of the child was so recent that when the body was found it was quite warm. It also became rigid in the usual time. The medical witness relied upon warmth and rigidity in the body as proofs of the child's having been born alive, when it is obvious that these conditions can prove only that the child has been recently living. The neglect to examine the body led to an acquittal. There was no proof of life as the result of breathing, and

no evidence to show whether the injuries were inflicted before or after death.

Respiration before or during birth.—It has been already stated that the pulmonary tests are fitted to prove whether a child has or has not *lived to breathe*. Neither the hydrostatic nor any other test can positively show that the body of a child was entirely *born alive* when the act of breathing was performed. As this is a subject that generally gives rise to some discussion in cases of child-murder, I shall here make a few remarks on it. 1st. Respiration may be performed while the child is in the uterus, after the rupture of the membranes—the mouth of the child being at the os uteri. This is what is termed *vagitus uterinus*; its occurrence, although extremely rare, seems to me to rest upon undisputed authority. 2dly. A child may breathe while its head is in the vagina, either during a presentation of the head or of the breech. This has been termed *vagitus vaginalis*. It is not very common, but it must be set down as a possible occurrence. 3dly. A child may breathe while its head is protruding from the outlet; in this position respiration may be as completely set up in a few moments by its crying, as we find it in some children that have actually been born, and have survived their birth several hours. This is the most usual form of respiration before birth. In the *vagitus uterinus* or *vaginalis* the lungs receive but a very small quantity of air; in respiration after protrusion of the head, the lungs may be sometimes found moderately well filled, although never perhaps possessing all the characteristic properties of those which have fully breathed. The well-known occurrence of respiration under either of these three conditions, strikingly displays the fallacy of making this process, as some have done, the certain boundary of extra-uterine life. A child may breathe in the uterus or vagina, or with its head at the outlet, and die before its body is born; the discovery of its having respired would not, therefore, be any sort of proof of its having enjoyed what has been termed “extra-uterine life.” (For a well-marked case of this kind, see “Med. Gaz.,” vol. 38, p. 394; and another, communicated to me by Dr. Crothers, of Coy, will be found in “Guy’s Hospital Reports,” October, 1850, p. 231.) The death of a child which has breathed in the uterus or vagina, from natural causes before its entire birth, is a possible occurrence; but its death from natural causes before birth, after it has breathed by the protrusion of its head from the outlet, is an unusual event. All that we can say is—it may take place; but death under these circumstances would be the exception to a very general rule. Oberkamp states that, in four successive deliveries of the same woman, the children breathed during delivery, but died before they were born.

Respiration a sign of life, not of live birth.—The hydrostatic test is only capable of determining that *respiration has taken place*; it cannot show whether this process was established during birth or afterwards. The fact of a child having the power of breathing before it is entirely born, does not therefore constitute the smallest objection to its employment; although, upon this ground, we find the use of it, in any case, denounced by many members of the medical and legal professions. It is obvious that most members of the law who have treated this subject,

have adopted, without sufficient examination, the statements of Dr. William Hunter. This author observes: "A child will commonly breathe as soon as its mouth is born or protruded from its mother; and in that case may lose its life before its body be born, especially when there happens to be a considerable interval between what we may call the birth of the child's head and the protrusion of its body. And if this may happen where the best assistance is at hand, it is still more likely to happen when there is none; that is, where the woman is delivered by herself." ("On the Uncertainty of the Signs of Murder in the case of Bastard Children," p. 33.) Dr. Hunter here exposes, in plain language, the fallacy of trusting to the signs of respiration alone, as evidence of a child having been *born* alive. The truth of his remarks is, in the present day, generally admitted; and if, among medical and legal writers, we find some treating respiration as a certain proof of *live birth*, it is from their not having sufficiently considered the probability of a child breathing and dying before its body is entirely extruded.

Although it is obvious from the above cases that the test can prove no more than that a child has breathed, some medical witnesses, in giving evidence in cases of child-murder, still fall into the error of assuming that the hydrostatic test is capable of proving "live birth." Medical jurists of repute have sanctioned this erroneous view, ignoring the fact that the child may breathe and die before the entire birth of the body, while the test cannot show whether the act of breathing was performed during birth or afterwards. Among others, the late Professor Casper, of Berlin, expresses his opinion that if we find air in the lungs of a new-born child, such a child must have been born alive. The reasoning of Casper is as extraordinary as his conclusion. He says: 1. During a rapid delivery those conditions are wanting which lead to breathing in utero or during birth. 2. All cases of secret delivery are rapid, and it is in these cases only that the hydrostatic test can be applied to the lungs; hence the proof of breathing in a secretly-born child must be regarded as breathing after, and not in or during birth ("muss jedes von der Athemprobe nachgewiesene Geathmethaben eines heimlich gebornen Kindes als ein Athmen nach (nicht in oder vor) der Geburt, das Kind folglich als ein *lebend geboren* gewesenes erachtet werden." "Gerichtliche Medicin," vol. 1, p. 710). It will be seen that this medical jurist entirely ignores the facts pointed out by Dr. W. Hunter eighty years ago, and accumulated by numerous obstetric authorities since that time.

On a late trial for child-murder, a medical witness being asked on what he based his statement that the child had been born alive, said: The presence of air in the lungs, and quoted Casper as his authority. There may be cases in which the signs of full respiration would justify an opinion of live-birth, but the dictum of Professor Casper is quite inadmissible. The floating of the lungs in water may be owing to air received before or during birth, and it cannot be admitted that all cases of secret delivery are necessarily rapid cases—so rapid that the child has had no time to breathe until after entire birth.

(The reader will find a good summary of the mode of applying the

hydrostatic test, as well as of the conclusions which may be drawn from its proper application, by M. Devergie, in the "Ann. d'Hyg." for 1872, 2, 169. See also a paper by the late M. Tardieu, "Ann. d'Hyg.," 1867, 2, 217 and 365.)

Conclusions.—The general conclusions respecting the employment of the hydrostatic test, to be drawn from the contents of this chapter, are—

1. That the artificial inflation of the lungs of a child born dead will cause them to float in water.

2. That lungs artificially inflated while in the chest, resemble those organs in which respiration has been only imperfectly established.

3. That in cases of inflation of the lungs in the chest, the air may be generally expelled from the divided portions of lung by firm compression, causing them to sink.

4. That the same result occurs with lungs in which respiration has been imperfectly established.

5. That when lungs have undergone perfect respiration, the air cannot be expelled by compression of the divided parts, so as to cause them to sink.

6. That the artificial inflation of foetal lungs causes no alteration of weight, and as the weight increases in proportion to the degree of respiration, so in healthy lungs, with great buoyancy, there should be great weight if the air has been derived from respiration.

7. That we should base our judgment of a child having breathed upon great weight and great buoyancy of the lungs combined—that the one condition without the other is open to the objection that the air may not have been derived from respiration,

8. That the floating of the lungs in water proves, *cæteris paribus*, that a child has breathed either at, during, or after birth: it does not prove that a child was born alive, or that it has died a violent death.

9. That the sinking of the lungs as a result of the expulsion of air from them by compression, does not necessarily prove that the child was born dead. It merely proves that the air contained in them was derived either from artificial inflation, or from the imperfect establishment of the respiratory process.

10. That the hydrostatic test is not applicable to determine the fact of respiration or non-respiration in all cases of alleged child-murder; but that, with ordinary precautions, it may safely be employed in the majority of such cases.

11. That a child may breathe before, during, or after birth, but the hydrostatic test will not enable us to say, in the greater number of cases, at which of these periods the act of breathing was performed.

12. That breathing is a sign of life, and not necessarily of live-birth.

13. Hence, in order to constitute murder, medical evidence is required to show whether a child had breathed *after* it was entirely born, and whether the act of violence which caused its death was applied to it while so breathing.

These conclusions are here expressed with brevity. Some of them may require qualification; but for the circumstances which qualify them the reader is referred to the contents of the chapter.

CHAPTER LI.

ON THE PROOFS OF A CHILD HAVING BEEN BORN ALIVE.—EVIDENCE FROM RESPIRATION.—FROM MARKS OF VIOLENCE.—FROM NATURAL CHANGES IN THE FŒTAL VESSELS.—FROM THE DISCOVERY OF FOOD IN THE STOMACH.—GENERAL CONCLUSIONS.

ON a trial for child-murder, the important medical question has hitherto been: Was the child completely born alive? The interpretation set upon these words by all the judges is that the whole body of a child should be entirely delivered from the body of the mother before the question of its death from violence could be entertained. In cases in which death had obviously taken place from criminal violence, the medical witness was suddenly stopped in his evidence by being asked for some infallible proof of live birth in a *legal* sense. As a medical man not present at the delivery could rarely be in a position to offer such proof, the case broke down, and the accused, however morally guilty, was acquitted. With such technical facilities for evading the law, it is not surprising that cases of alleged infanticide should be so frequent, and that the crime should be on the increase. Dr. Hardwicke, one of the coroners for Middlesex, stated that in one year only he held two hundred inquests on the bodies of illegitimate children.

By the existing law, it is murder to cause a child to die after it is born by injuries inflicted on it before or during birth; but it is no offence to kill a living child while it is being born, unless miscarriage is caused! Under the new criminal code proposed by Sir J. Stephen, there is the following enactment against the murder of *unborn children*: "Every one shall be liable to penal servitude for life who causes the death of any living child which has not proceeded in a living state from the body of its mother by any act or omission which would have amounted to murder if such a child had been fully born."

For the protection of medical men who perform craniotomy, or who otherwise destroy an unborn child, it is provided that no one shall be guilty of any offence who, by means employed in good faith, for the preservation of the life of the mother of the child, and reasonably necessary for that purpose, causes the death of any such child, or causes any child to die after it is fully born by any such thing done before or during its birth.

This proposed change may be objected to on a technical ground—namely, that it creates a difference in the crime of murder, making it to depend, not on the fact of killing, but on the time at which the killing takes place. The answer to this objection is, however, that under the present law many escape who deserve punishment, and that real cases of child-murder practically go unpunished. Under the new code,

uries will be less ready to acquit women charged with this crime when a sentence of penal servitude can be passed on them, in place of capital punishment.

As the question of live birth must still, as a rule, be put to the witness on charges of child-murder, it will be necessary to consider the medical facts upon which reliance can be placed, as furnishing evidence of a child having come into the world living, or of its having been born alive.

Evidence from respiration.—As a general rule, there will be no perceptible difference in the state of the lungs, whether the act of respiration is performed by a child during birth or after it is born, provided that its death speedily follows its birth. But should we find that this process has been *perfectly established, i. e.*, that the lungs present all those conditions which have been described as characteristic of full and perfect breathing, there is great reason to presume that the process, even if it had commenced during birth, must have continued after the child was entirely born. This presumption becomes still stronger when the child is immature; for, generally speaking, such children must be born and continue to breathe for many hours after birth, in order that their lungs should present the characters of complete respiration. The process is seldom so established before birth as to give these organs a feeling of crepitation under pressure; the existence of this character should, therefore, be sought for. A witness who relied upon it as a conclusive proof of breathing *after* birth, might be asked by counsel, whether it were not possible for some children to remain so long at the outlet with the head protruding, as to render the lungs crepitant from frequent respiration *before* birth. Admitting the bare possibility of this occurrence, he should endeavor to ascertain whether there was any probable cause which could thus have protracted delivery while the head of the child was in this position; as also, what natural cause could have produced its death when its head was protruding and respiration had been so freely performed as to give crepitation to the lungs. The presence or absence of the usual scalp-tumor might throw some light upon the case. If, when present, it did not prove live birth, it might indicate protracted delivery, and show that the child had been recently living. The late Professor Casper, of Berlin, has cut the Gordian knot of this difficulty, by assuming that breathing before birth takes place only in protracted delivery, in which the assistance of an accoucheur is required. In those cases which are likely to give rise to criminal investigations, he assumes that the birth of the child takes place quickly, and that in rapid delivery the child does not breathe until after it has been born alive. Hence his conclusion is—if in the body of a child (secretly disposed of) the lungs are found by the hydrostatic test to contain air, this air did not enter the lungs at or before birth but afterwards, and that the child was born alive. (“*Gerichtl. Medicin*,” vol. 1, p. 710.) Such a conclusion is not in accordance with the facts ascertained regarding the respiration in new-born children; it may be that they rarely die from natural causes after they have once breathed, but that they can breathe and cry during birth, is a fact which cannot be disputed. Further, there is no test known by which air received into

the lungs during birth, can be distinguished from that which has entered these organs after the child has been born alive.

Evidence from marks of violence.—If marks of violence, apparently inflicted about the same time, are found on different and remote parts of the body, and these marks bear the characters of those produced during life, it is rendered probable that the whole of the body of the child was in the world when they were caused. Marks of severe violence on one part, as the head or breech, would not always justify such a presumption, because it might be fairly objected that they had been unintentionally produced by the woman in her attempts at self-delivery, and yet the child not been born alive. It would be for a witness to form an opinion from the circumstances accompanying the particular case, whether they had been thus occasioned. From this it will be seen that, in making an examination after death, it is proper that every mark of injury on the body of a child, even if slight, should be noted down. Abrasions of the skin, burns, and punctures, should be sought for, and the throat examined for marks of pressure by a cord or by the fingers.

Evidence from certain changes in the body.—In a child that has been born alive, or has survived its birth for a period of from twelve to twenty-four hours, that portion of the umbilical cord which is contiguous to the abdomen undergoes certain changes: it dries and becomes slowly shrivelled, and in from three to five days it separates from the body with or without cicatrization.

The cord does not separate at the part which is tied, but close to the abdomen. It separates generally within five days, by a process of sloughing, the skin connected with the dead portion of the cord presenting a red line, arising from capillary congestion. During the separation of the navel-string the umbilical vessels are gradually closed. According to Billard, the obliteration of these vessels is effected in a peculiar manner. The calibre diminishes as a result of a concentric thickening of the coats, so that, while the vessel retains its apparent size, its cavity is gradually blocked up. A quill would represent the form of the vessel in the foetal state, and a tobacco-pipe in the obliterated state. It is only by cutting through the vessel that the degree of obliteration can be determined. The state of the *umbilical cord* has furnished good evidence of live birth, when the other circumstances of the case have yielded no information. The changes in the umbilical cord, especially those indicative of its separation and cicatrization, clearly prove that a child has survived its birth, whatever may be the results of experiments on the lungs; but the difficulty is, that they require some days for their production, and in practice it is necessary to procure some sign of survivorship for only a few minutes, or at furthest for a few hours. The same remark applies to the *exfoliation of the cuticle* in a new-born child: such a condition of the skin can rarely be found in cases of infanticide. The absence of meconium from the intestines, and of urine from the bladder, are not proofs of live birth, for these may be discharged during birth and yet the child not be born alive.

State of the skin.—In the greater number of new-born children, the skin has a dark red color, probably owing to the first effect of the atmosphere upon it. Within an hour it begins to get of a lighter red,

and so it remains for one or two days. According to Dr. Elsässer, it becomes again darker about the end of the second, or on the third day, and is then of a brownish-red color. This lasts for three or four days, unless a yellowness appears from jaundice. It is then more or less yellow. It is about the sixth or seventh day that the skin acquires a reddish-white color, such as it afterwards retains. (Henke's "Zeitschrift der S. A.," 1842, vol. 2, p. 223.)

Evidence from changes in the heart and foetal vessels. Docimasia circulationis.—It has been supposed that the state of the ductus arteriosus, ductus venosus, and foramen ovale would aid a medical jurist in forming an opinion whether a child had survived its birth. In general, as a result of the establishment of respiration, it is found that the communication between the auricles of the heart by the foramen ovale becomes closed; and that the two vessels or ducts, after gradually contracting, become obliterated, or are converted into fibrous cords. Whatever may be the conclusions from experiments on the lungs, it has been contended that the closure of the foramen and of these vessels would infallibly indicate that a child had breathed. This inference, however, has been too hastily drawn. Recent researches have shown that there are some serious objections to any conclusions based on the state of these foetal vessels; their closure, as a natural process, always takes place slowly, and sometimes is not completed until many years after birth. Thus, then, in the generality of cases of infanticide, in which necessarily the child survives but for a short period, no evidence of the fact will be procurable from an examination of the heart and foetal vessels.

Ductus arteriosus (Arterial duct).—The ductus arteriosus is a vessel about half an inch long, which in the foetus forms a direct communication between the right ventricle of the heart and the aorta; it conveys the larger proportion of the blood from the heart to the aorta without passing through the lungs. As soon as respiration is established its function is at an end, and it then begins to close. In Figs. 62 and 63 the different parts of the foetal heart are seen in outline—in Fig. 62 as they appear before, and in Fig. 63 as they appear after, perfect respiration: 1, the aorta; 2, the pulmonary artery; 3 3, the right and left branches of the pulmonary artery going to the right and left lungs; 4, the ductus arteriosus, short and wide in Fig. 62, and in Fig. 63 contracted at the end where it joins the under part of the arch of the aorta. Professor Bernt of Vienna, who has made many observations on this subject, drew the following conclusions respecting the period required for the closure of the ductus arteriosus in children which have been born alive and have lived after birth. 1. If a child has lived only a *few seconds*, the aortal end of the duct appears contracted, and the vessel, instead of being cylindrical throughout, acquires the form of a truncated cone. 2. If a child has lived for *several hours*, or a *whole day*, the duct becomes again cylindrical, although shortened and contracted in diameter. Its size is about equal to a goose-quill; it is, therefore, much smaller than its root, and about as large as either of the two branches of the pulmonary artery, which have in the mean time become increased in size. 3. If a child has lived for *several days* or a *whole week*, the duct contracts to the diameter of a few lines—about equal to a crow-quill,

while the two branches of the pulmonary arteries are equal in size to a goose-quill. 4. The duct is found perfectly closed and quite impervious at a much later period, *i. e.*, after the lapse of an uncertain number of weeks or even months.

Fig. 62.

Heart of the new-born child with the ductus arteriosus in its foetal state.

Fig. 63.

Heart of the child with the duct undergoing contraction as the result of the establishment of respiration.

As a general rule, the peculiar parts of the foetal circulation are rarely obliterated by a normal process before the eighth or tenth day after birth. The obliteration, according to Bernt and Orfila, takes place in the following order: 1. The umbilical arteries; 2. The ductus venosus; 3. The ductus arteriosus; and 4. The foramen ovale. (Orfila, "*Méd. Lég.*," 1848, vol. 2, p. 210.) The circumstances connected with the closure of these foetal vessels have been statistically investigated by Dr. Elsässer. Among 70 still-born children they were found open in 69. Among 300 children who died soon after birth, 80 out of 108 prematurely born and living from one to eight days, presented all the passages open; 127 out of 192 infants born at the full time had all the passages open, but partly contracted. The ductus arteriosus was open in 55 cases, and completely closed in 10 cases; the ductus venosus was open in 81, and completely closed in 37 cases; while the foramen ovale was open in 47, and completely closed in 18 cases only. These facts, according to Dr. Elsässer, prove that the vessels peculiar to the foetal circulation remain open as a rule for some time after birth, and that it is not possible to determine accurately, by days, the period of their closure. This physiologist remarked that the closure commenced and was often completed in the ductus venosus, before it manifested itself in the other vessels. The complete closure, in by far the greater number of cases, takes place within the first six weeks after birth, and the instances of obliteration before birth, or before the period mentioned after birth, must be regarded as rare exceptions. ("*Med. Times and Gaz.*," May 21, 1853, p. 530.)

From these facts, the *docimasia circulationis* may be considered as useless to a medical jurist. It either proves nothing, or it may lead to a fatal error. It is the more necessary to point out the fallacies to which it is liable, because hitherto medical jurists have been disposed

to place great reliance upon it, in cases in which medical evidence from the state of the lungs was wanting.

Evidence from the state of the alimentary canal.—Good evidence of live birth may be sometimes derived from the discovery of certain liquids or solids in the stomach and intestines, such as blood, milk, or farinaceous or saccharine articles of food; for it is not at all probable that these substances should find their way into the stomach or intestines of a child which was really born dead.

1. *Starch.*—In the case of a new-born child, the late Dr. Geoghegan discovered, by the application of iodine-water, the presence of farinaceous food in the contents of the stomach: hence the question of live birth was clearly settled in the affirmative. On another occasion Dr. Francis employed this method of testing with satisfactory results, in a case in which the investigation was beset with unusual difficulties. He was required by the coroner to examine the body of a new-born child, found under suspicious circumstances. The examination of the lungs left no doubt that respiration had taken place; and the fact that the child had been born alive was fully established by the discovery in the stomach of a small quantity of farinaceous food. On digesting in distilled water a fragment of the pulp found in this organ, and adding a drop of solution of iodine, an intense indigo-blue color appeared immediately. The application of this chemical test, therefore, removed any doubts which might have been entertained on the question of live birth. ("Med. Gaz.," vol. 87, p. 460.) The quantity of starch present may, however, be too small to produce with water a solution which would be colored by iodine in the manner described. A portion of the contents of the stomach should be placed on a glass-slide, diluted with a little water if viscid, and examined under the microscope with a power of about 300 diameters. The granules (if present) may then be distinctly seen, having the shape peculiar to each variety of starch, and not unfrequently mixed with oil-globules and epithelial scales derived from the mucous membrane. By the addition of strong iodine-water their shape and size will be brought out by the intensely blue color which they acquire. Blue fragments of an irregular shape indicate the presence of bread. The annexed engraving (Fig. 64) represents two varieties of starch, either of which may be found in the stomachs of infants; in *a* the rounded granules of wheat-starch are represented, and in *b* the ovoid granules of arrowroot. The micrometrical measurements of these granules show, for those of wheat which are irregularly spherical, diameters varying from 1-9000th to 1-1125th of an inch in size. Many have an average diameter of 1-3000th of an inch. The ovoid granule of arrowroot is 1-900th of an inch in length, and 1-1800th of an inch in width.

2. *Sugar.*—In a case which I was required to examine, the presence of sugar was readily detected in the contents of the stomach by the application

Fig. 64.

a. Granules of wheat starch. b. Granules of arrowroot. Magnified 310 diameters.

of Trommer's test. In order to apply this test, a few drops of a weak solution of sulphate of copper should be added to a portion of the cold concentrated aqueous extract of the contents of the stomach. An excess of a solution of pure potash is then added, and the liquid boiled. If sugar be present, the suboxide of copper is immediately precipitated of a yellowish or reddish color. With white sugar the same decomposition is effected, but more slowly. If starch only is present, black oxide of copper may be thrown down, but there will be no production of a red precipitate. The formation of the red oxide of copper under these circumstances proves that some saccharine substance is present. In reference to the application of the sugar test, however, it must be remarked that starch is easily convertible into sugar by a chemical action of saliva or mucus, so that the test may appear to indicate sugar in small quantity, when the result may be really due to the presence of some converted starch.

3. *Milk*.—This liquid may be found in the stomach of a new-born child; it may be identified microscopically in the fluids of the stomach by the numerous and well-defined oil-globules which it contains. It is not possible to distinguish human from cow's milk under these circumstances. In both, the globules which are spherical in all aspects (figs. 65 and 66), are remarkable for their transparency in the centre, and their dark margins. They vary considerably in size. I have found those of the cow to have by measurement the following diameters: Maximum, 1-2200th of an inch; minimum, 1-18000th; and medium size, 1-4500th of an inch. They are distinguished from blood-corpuscles by their shape and lustre, and from starch-granules by the fact that they are not colored or changed by iodine-water. *Colostrum* is the name applied to the milk first secreted after delivery; it contains, in addition to oil-

Magnified 460 diameters.

globules, numerous spherical granular bodies (fig. 66, *b*). When milk is present, *lactine* or sugar of milk is generally found in the contents of the stomach by the appropriate sugar-test (*supra*). The casein, or solid principle of milk, precipitates oxide of copper from the sulphate; but on adding an excess of a solution of potash, the oxide is redissolved, form-

ing a purple or violet-colored solution. It is rapidly coagulated by the digestive principle (pepsine) contained in the gastric juice, so that the casein may be found in small soft masses adhering to the lining-membrane of the stomach. It should be observed that albumen forms a deep violet-colored solution with sulphate of copper and potash, but the red suboxide of copper is not precipitated on boiling unless sugar is mixed with it.

4. *Epithelial scales*.—The epithelial scales commonly found associated with articles of food in the stomach are of various shapes and sizes; they are flat, oval, or rounded, and sometimes polygonal. They are nucleated, and from their pavement-like appearance they are called “tesselated.” In fig. 67, *b*, an epithelial scale from the mucous membrane of the inside of the mouth, is represented magnified 570 diameters. In the long axis it was the 1-500th of an inch, and in the shortest 1-900th of an inch in diameter. The central nucleus was 1-4000th of an inch in diameter, and the small granules around it 1-9000th of an inch. These epithelial scales are very numerous, much intermixed, and so thin and transparent that they are often only distinctly seen at the edges, which are occasionally folded or slightly turned over.

Tesselated epithelial scales.
a, from Sharpey; *b*, from observation.

Besides the substances mentioned, other solids and fluids, such as blood and meconium (the fecal discharges of the foetus) may be found in the stomach of a new-born child, and a question may arise whether their presence indicates that the child was fully born. It is not impossible that a child might be fed and might exert a power of swallowing when its head had protruded from the outlet, and its body was still within the body of the mother. Children have been known to exert a power of sucking or aspiration under these circumstances, and with this, a power of swallowing might be exercised. In defending a prisoner on a charge of child-murder, counsel would scarcely resort to a defence of this kind. That the starch, sugar, or milk, etc., found in the stomach, should have been given to a child when its body was only half born, is so improbable an hypothesis that the most inexperienced lawyer would hardly resort to it to account for the presence of food in this organ. When the substances found in the stomach are not in the form of food, but are fluids connected with the child or the mother, the case is different. These may penetrate into the lungs or stomach during birth, either by aspiration or by the act of swallowing: they thus indicate that the child was living, but they do not necessarily show that its body was entirely in the world when they were swallowed.

5. *Blood*.—An instance is related by Dr. Döring in which a spoonful of coagulated blood was found in the stomach of a new-born child. The inner surfaces of the gullet and windpipe were also covered with blood. Dr. Döring inferred from these facts that the child had been born alive; for the blood, in his opinion, could have entered the stomach only by

swallowing, *after* the birth of the child, and while it was probably lying with its face in a pool of blood. Taken alone, however, such an inference would not be justifiable from the facts as stated. Blood might be accidentally drawn into the throat from the discharges of the mother during the passage of the child's head through the outlet, and yet the child may not have been born alive. The power of swallowing may be exerted by a child during birth, either before or after the act of breathing. This power appears to be exerted even by the foetus in utero. Blood may be recognized in the contents of the stomach, not only by the color which it imparts to the mucous liquids present, but by the aid of the microscope. This subject has been already fully considered in another part of this work (p. 304).

Dr. Robinson has made some researches on the contents of the foetal stomach during uterine life. He finds that the substances which naturally exist in the stomach of a foetus before birth are of an albuminous and mucous nature. His observations were made on the stomachs of two human foetuses, and on those of the calf, lamb, and rabbit. The conclusions at which he arrived were:—that the stomach of the foetus, during the latter period of its uterine existence, contains mucous and albuminous matters derived from the salivary secretion, and that gastric juice is not secreted until after respiration has been established. The medical jurist will perceive, therefore, that the discovery of farinaceous food, milk, or sugar in the stomach will furnish evidence of birth, since substances of this kind are not found naturally in this organ.

6. *Meconium*.—This name is applied to the excrementitious matter produced and retained in the intestines during foetal life. It may be found in the stomach of a new-born child, and a question will thence arise, whether its presence there should be taken as a proof of entire live birth. It may be discharged from the child during delivery, in cases in which there is a difficult or protracted labor. During the act of breathing it may enter the throat with other discharges, and thus be found in the stomach. That a breathing child can thus swallow meconium cannot be disputed, but, assuming that in the body of a child which has not lived to breathe, this substance is found in the air-passages and stomach, how is the conclusion affected? From a case which occurred to Dr. Fleischer, it is probable that some portion of the meconium may be discharged from the bowels of a child during labor, and as the mouth passes over this liquid a portion may be drawn into the throat by aspiration. When once there, the instinctive act of swallowing would immediately convey a portion of it into the stomach. (See the report of a case in Casper's "Vierteljahrsschrift," 1863, vol. 1, p. 97; also for another case, "Med. Times and Gazette," August 3, 1861, p. 116.)

The presence of fluids, therefore—such as *blood*, *meconium*, or the watery discharges attending delivery—in the stomach and air-passages of a new-born child, does not prove live birth, but merely indicates the existence of some living actions in the child at or about the time of its birth. In a case which occurred to Dr. Ramsbotham, a woman was suddenly delivered of a child while sitting over a slop-pail of dirty water. On examining the body, it was obvious that it had not breathed. There was no air in the lungs, but a quantity of dirty water, like that in the pail, was found in the stomach. This could have

entered the organ only by the act of swallowing, and, in Dr. Rambotham's opinion, the child had swallowed the liquid under some foetal attempt to breathe. The coroner who held the inquest directed the jury that the child was born dead; but most physiologists will consider that the power of swallowing cannot be exerted by a dead child; and as its body must have been entirely delivered in order to have fallen into the liquid, there was proof that it had been born living, and that in this instance it had died after it was entirely born, by the prevention of the act of breathing. The facts connected with the aspiration of liquids by new-born children, have been lately fully examined by Dr. E. Hofmann (Eulenberg's "Vierteljahr.," 1878, 2, p. 228).

The *meconium* may be generally recognized by its dirty-green color and general appearance, as well as by the absence of any offensive odor, which it does not acquire until after the third or fourth day from birth, when it becomes mixed with feculent matter. Its microscopical characters are represented in the annexed engraving (fig. 68). In the air-passages it is sometimes associated with vernix caseosa, and hairs derived from the skin. ("Med. Times and Gazette," June 1, 1861, p. 591, and Aug. 3, 1861, p. 117; see also "Ann. d'Hyg.," 1855, vol. 2, p. 445.)

But little need be said on its chemical properties; still, as the detection of stains of meconium on clothing may occasionally form a part of the medical evidence, a few observations are here required. The stains which it produces are of a brownish-green color, very difficult to remove by washing. They stiffen the stuff, and are usually slightly raised above the surface, without always penetrating below it. Meconium forms with water a greenish-colored liquid, having an acid reaction; a boiling heat does not affect the solution. Nitric acid and sulphuric acid with sugar, yield with it the green and red-colored compounds which they produce with bile. Cholesterine may be separated from it by hot ether.

It may be remarked, in reference to stains produced by the feces of a child which has survived birth, that until the fifth or sixth day they retain a dark-green or greenish-yellow color. On the seventh day after birth, they generally acquire a bright-yellow color, like that of the yolk of egg; and if the child is in health, they will retain this color during all the time that it is suckled.

The slightest consideration will show that the various indications of live birth above described are weak, and of purely accidental occurrence. If a child is destroyed either during birth, or within a few minutes afterwards, there will be no medical evidence to indicate the period at which its destruction took place; the external and internal appearances presented by the body will be the same in the two cases. It is most probable that in

Fig. 68.

Microscopical appearance of meconium — a, crystals of cholesterine, b, epithelial scales; c, masses of green coloring-matter of bile (biliverdin); d, e, granules. Magnified 400 diameters.

the greater number of instances of child-murder, a child is actually destroyed either during birth, or immediately afterwards; and, therefore, the characters above described can rarely be available in practice. If any exception is made, it is with respect to the nature, situation, and extent of marks of violence; but the presence of these depends on mere accident. Hence, then, we come to the conclusion that although medical evidence can generally show, from the state of the lungs, that a child has really lived, it can rarely be in a condition to prove in a case of infanticide, that its life had certainly continued after its entire birth. We could only venture upon this inference when the signs of breathing were full and complete, or when some article of food was found in the stomach.

Conclusions.—The general conclusions which may be drawn from the facts contained in this chapter, on the question whether a child has or has not been *born alive*, are as follows:—

1. That if the lungs are fully and perfectly distended with air by the act of breathing, this affords a strong presumption that the child has been *born alive*, since breathing during birth is in general only partial and imperfect.

2. That the presence of marks of severe violence on various parts of the body, if possessing vital characters, renders it probable that the child was born alive when the violence was inflicted.

3. That certain changes in the umbilical vessels, and the separation (by a vital process) and cicatrization of the umbilical cord, as well as a general peeling or scaling-off of the cuticle, indicate live birth.

4. That the absence of meconium from the intestines and of urine from the bladder, are not proofs that a child has been born alive, since these liquids may be discharged during the act of birth.

5. That the open or contracted state of the foramen ovale or ductus arteriosus furnishes no evidence of a child having been born alive. These parts may become close and contracted *before birth*, and therefore be found closed in a child born dead; or they may remain open after birth in a child born living, even subsequently to the establishment of respiration.

6. That the presence of farinaceous or other food in the stomach proves that a child has been entirely born alive.

7. That the presence in the stomach and air-passages of blood, meconium, vernix caseosa, or the natural discharges, does not prove that a child was born alive.

8. That, irrespective of the above conclusions, there is no certain medical sign which indicates that a child that has died at or about the time of birth, has been born alive.

CHAPTER LII.

CAUSES OF DEATH IN NEW-BORN CHILDREN.—PROPORTION OF CHILDREN BORN DEAD.—NATURAL CAUSES OF DEATH.—A PROTRACTED DELIVERY.—DEBILITY.—BLEEDING FROM LACERATION OF THE NAVEL-STRING.—COMPRESSION OF THE NAVEL-STRING.—MALFORMATION.—DESTRUCTION OF MONSTROUS BIRTHS.—DEATH FROM CONGENITAL DISEASE.

Causes of death in new-born children.—The next important question in case of infanticide, and that upon which a charge of murder essentially rests, is—What was the cause of death? 1. It is admitted that a child may die during birth or afterwards. 2. In either of these cases it may die from *natural* or *violent causes*. The violent causes may have originated in *accident* or in *criminal design*. The last condition only involves the corpus delicti of child-murder. If death has clearly proceeded from natural causes, it is of no importance to settle whether the cause operated during or after birth. All charge of criminality is thenceforth at an end.

It is well known that of children born under ordinary circumstances, a great number die from *natural causes* either during birth or soon afterwards; and in every case of child-murder, death will be assumed to have arisen from some cause of this kind until the contrary appears from the medical evidence. This throws the onus of proof entirely on the prosecution. Many children die before performing the act of respiration; and thus a large number come into the world dead or still-born. The proportion of *still-born* among legitimate children, as it is derived from statistical tables extending over a series of years, and embracing not fewer than eight millions of births, varies from one in eighteen to one in twenty of all births. (“Brit. and For. Med. Rev.,” No. 7, p. 235.) In immature and illegitimate children, forming the greater number of those which give rise to charges of child-murder, the proportionate mortality is much greater,—probably about one in eight or ten. Still-births are much more frequent in first, than in after pregnancies: and children are much more frequently born dead among primiparous than among pluriparous women. According to Dr. Lawrence’s observations, the proportion of deaths is 1 to 11 among the primiparous and 1 to 31.2 among the pluriparous. (“Edin. Med. Jour.,” March, 1863, p. 815.) In most cases of child-murder the woman is primiparous. These facts should be borne in mind when we are estimating the probability of the cause of death being natural.

Should breathing be established by a protrusion of the child’s head from the outlet, or during the birth of the body, the chances of death from natural causes are considerably diminished. Nevertheless, as Dr. Hunter long ago suggested, a child may breathe and die. Thus, according to this author,—“If the child makes but one gasp and instantly dies,

the lungs will swim in water as readily as if it had breathed longer and had then been strangled." In general it would require more than one gasp to cause the lungs to swim readily in water; but waiving this point, the real question is,—If the child breathed either during or after birth, what could have caused its death? The number of gasps which a child may make, or which may be required for the lungs to swim in water, is of no moment: the point to be considered is, whether its death was due to causes of an accidental or criminal nature. So again observes Dr. Hunter: "We frequently see children born, who, from circumstances in their constitution or in the nature of the labor, are but barely alive, and after breathing a minute or two, or an hour or two, die, in spite of all our attention. And why may not this misfortune happen to a woman who is brought to bed by herself?" (Op. cit.) The substance of this remark is, that many children may die naturally after having been born alive; and in Dr. Hunter's time these cases were not perhaps sufficiently attended to. In the present day, however, the case is different; a charge of child-murder is seldom raised, except in those instances where there are the most obvious marks of severe and mortal injuries on the body of a child; and unless it be intended to defend and justify the practice of infanticide, it must be admitted that the discovery of violence of this kind on the body of a new-born infant, renders a full inquiry into the circumstances necessary. Among the *natural* causes of the death of a child may be enumerated the following:—

1. *A protracted delivery.*—The death of a child may proceed, in this case, from injury suffered by the head during the violent contractions of the uterus, or from an interruption to the circulation in the umbilical cord before the act of breathing can be performed. As it is elsewhere explained (*post*, p. 638) each contraction of the uterus affects the placental circulation, and a succession of these contractions in a protracted delivery will have the same effect on the child as the arrest of breathing after birth, *i. e.* non-oxygenated blood will be circulated, and may cause the death of the child. For a similar reason a premature separation of the placenta may lead to its death.

A child, if feeble and delicate or if prematurely born, may die from exhaustion under these circumstances before respiration is established. This cause of death may be suspected when a sero-sanguinolent tumor (called *cephalæmatoma*, or *caput succedaneum*) is found on the head of a child, and the head itself is deformed or elongated as a result of pressure. This appearance will be accompanied with a congested state of the vessels of the brain. The existence of deformity in the pelvis of the woman might corroborate this view; but in primiparous women (among whom charges of child-murder chiefly lie) with well-formed pelves, delivery is frequently protracted. It is presumed that there are no marks of violence on the body of the child, excepting those which may have reasonably arisen from accident in attempts at self-delivery.

2. *Debility.*—A child may be born either prematurely or at the full period, and not survive its birth, owing to a natural feebleness of system. This is observed among immature children; and it is a condition especially dwelt on by Dr. Hunter. Such children may continue in existence for several hours, breathing feebly, and may then die from mere weak-

ness. These cases may be recognized by the immature condition of the body and the appearance of a general want of development.

3. *Bleeding from laceration of the navel-string.*—A child may die from loss of blood, owing to a sudden separation of the placenta or an accidental rupture of the navel-string. In the latter case it is said the loss of blood is not likely to prove fatal if breathing has been established; but an instance is reported in which a child died from bleeding even under these circumstances. (Henke's "Zeitschrift," 1839, Erg. H., p. 200; also, 1840, vol. 1, p. 347, and vol. 2, p. 105; "Ann. d'Hyg.," 1831, vol. 2, p. 128.) Bleeding from the cord has been observed to take place at various periods after birth, and to have led to the death of the child ("Edin. Month. Jour.," July, 1847, p. 70). Death from bleeding may be commonly recognized by the blanched appearance of the body, and a want of blood in the internal organs; but there are several instances on record, in which the cord was ruptured close to the abdomen without causing the death of the child. Bleeding from the vessels of the navel-string may prove fatal several days after birth, even when a child has been properly attended to, and the navel-string has separated by the natural process. Mr. Willing has reported a case of this kind, in which, in spite of every application, the child died from loss of blood six days after the cord had separated. ("Med. Times and Gaz.," March 25, 1854, p. 287.) The impossibility of arresting the bleeding in this case appeared to depend upon a great deficiency of fibrin in the blood, and a consequent want of tendency to coagulation. (See on this subject a paper by Dr. Wieczorek, Eulenberg's "Vierteljahr.," 1873, 1, p. 385.)

It has been hitherto believed that the danger arising from bleeding of the cord, was chiefly confined to those cases in which it was divided near to the abdomen, and where a cutting instrument has been used, and this is no doubt generally true. Dr. Page performed some experiments on this subject which showed that hemorrhage might take place from the divided navel-string, even when torn through at a length of eighteen inches from the body, and to such an extent as to endanger the life of a child. He also found that hemorrhage from the cord might take place without any interference with the respiration; but the arrest of this may lead to hemorrhage which might not otherwise have occurred.

If there are severe wounds on the body from which blood has issued, it would be obviously wrong to refer a blanched condition of the body to accidental bleeding from the cord. The fatal bleeding may really have arisen from the wounds.

Before a medical expert refers death to this cause, he should be well assured that the cord was really torn through or severed about the time of birth, and not from any accident subsequently. A case is reported which shows the necessity for this caution. The body of a new-born child was taken from a river in which it had probably been floating for nearly a fortnight. The placenta and cord were attached to the body, but in removing it from the water the cord was torn through and the placenta carried away by the stream. A medical man examined the body, and seeing the cord ruptured, and observing no marks of violence, he came to the conclusion that the cord had been torn through by the

woman at birth, and that the child had died from hemorrhage. ("Ann. d'Hyg.," Oct. 1873, vol. 2, p. 443.) The medical opinion, however, was disproved by the evidence of witnesses.

4. *Compression of the navel-string.*—When a child is born by the feet or buttocks, the cord may be so compressed under strong uterine contraction that the circulation between the mother and child will be arrested, and the latter will die. The same fatal compression may follow when, during delivery, the cord becomes twisted round the neck. A child has been known to die under these circumstances before parturition, the cord having become twisted round its neck in the uterus. ("Med. Gaz.," Oct. 1840, p. 122; also, vol. 19, pp. 232, 233.) On these occasions the child is sometimes described to have died from strangulation, but it is evident that before the establishment of respiration, such a mode of expression is improper. There are few or no appearances indicative of the cause of death. There may be lividity about the head and face, with a mark or furrow on the neck, and congestion of the brain internally; it is, however, necessary to remember that the brain of a child is always more congested than that of an adult. Dr. E. Hofmann, of Innsbruck, considers that asphyxia is really the cause of death in children which have not breathed. He looks upon the placental circulation as vicarious to that of the lungs after birth, the arterial blood from the woman supplying the oxygen (derived from respiration) necessary to support the life of the unborn child. The amount of oxygen required for this purpose is exceedingly small, and, according to Schwartz and Pflüger, it is not sufficient to produce any difference of color in the blood of the umbilical vessels. (Eulenberg's "Vierteljahr.," 1873, vol. 2, pp. 219, 224.) Although, under compression of the cord, a child may die before breathing, from the want of a proper supply of oxygen through the blood, yet the appearances presented by the lungs would differ from those which are found in these organs after breathing has been once established. The cord sometimes by being coiled round the limbs or body produces deep depressions in the skin; in one observed instance the furrow thus caused was a quarter of an inch deep, the vessels at the base of the furrow being emptied of their blood, while those of the raised portions were congested. These appearances remained for some hours after birth. ("Brit. Med. Journ.," April 19, 1879, p. 587.)

5. *Malformation. Monstrosity.* There may be a deficiency or defect of some vital organ which would at once account for a child dying either during delivery or soon after its birth. Two cases are reported, in one of which the child died from an absolute deficiency of the gullet—the pharynx terminating in a cul-de-sac; in the other, the duodenum was obliterated for more than an inch, and this malformation had occasioned the child's death. ("Med. Gaz.," vol. 26, p. 542.) In a third, recorded by Mr. Fairbairn, a child was suffocated by a retraction of the base of the tongue, owing to defect of the frænum. ("Northern Journ. Med.," March, 1849, p. 278.) The non-establishment of respiration sometimes arises from the mouth and fauces of the child being filled with mucus. An enlargement of the thyroid gland has occasionally led to the death of a new-born child by suffocation. ("Edin. Month. Journ.," July, 1847, p. 64.) The epiglottis is sometimes fixed over the glottis so as

to prevent the entrance of air. In a case of this kind which occurred to Dr. Hicks, a child was saved by the introduction of a finger: the air suddenly rushed in, and the child was then enabled to breathe. But a child may be born in this state when no person is at hand to assist the woman; in this case it will die; and the lungs being found in the foetal or unexpanded condition, it will be pronounced still-born. Obstruction of the air-passages is a frequent cause of death among still-born children.

The varieties of *malformation* are very numerous, but there can be no difficulty in determining whether they are such as to account for death. Persons are not allowed to destroy monstrous births; and the presence of any marks of violence in such cases should be regarded with suspicion. It is the more necessary to make this statement, as there is an idea among the vulgar that it is not illegal to destroy a monstrous birth. Mr. Poole, of Cirencester, communicated to me a case which occurred some years since in his practice. A lady was delivered of a most hideous bicephalous (two-headed) monster. In his absence, and at the earnest solicitations of the friends, the nurse destroyed it. The question was—was this woman guilty of murder? The only case in reference to this point which is recorded by medico-legal writers, is that of two women who were tried at the York Assizes in 1812, for drowning a child which was born with some malformation of the head, in consequence of which it was not likely that it could survive many hours. It did not appear that there had been any malice or concealment on the part of the prisoners, who were not aware of the illegality of the act. (Paris and Fonlanque, "Med. Jur.," vol. 1, p. 228.) The absence of malicious intention would probably lead to an acquittal on a charge of murder, but such an act would doubtless amount to manslaughter; the degree of monstrosity or the viability of the offspring cannot be received as an extenuating circumstance. As to the first, if a liberty of judging of what was monstrous and what not, were conceded to any ignorant nurse, children simply deformed might be put to death on this pretence; as to the second, it is held in law that whoever accelerates death causes it—hence the fact that a child is not likely to live more than a few hours, does not justify the act of one who prematurely destroys it.

6. *Spasm of the larynx*.—Some children are born with uterine life, and on coming into the world make attempts to breathe, but, as Dr. Hicks has pointed out, owing to spasm of the larynx and retraction of the tongue, the air is unable to enter—the child dies soon after birth, and, on inspection, no air being found in the lungs, the child is wrongly pronounced to have been born dead. ("Guy's Hosp. Rep.," 1866, p. 176.) A careful examination of the fauces may show the presence of mucus or meconium, or a condition of the epiglottis which may account for the obstruction to respiration. Dr. Hicks has on more than one occasion seen the new-born child make these inspiratory efforts, and by lifting the epiglottis has given free passage to the air, and the child has been saved.

7. *Atelectasis*.—Atelectasis, as it has been elsewhere explained (*ante*, p. 609), implies simply an unexpanded state of the lungs. In some cases it is complete, in others partial. It can scarcely be regarded as a diseased condition, as the body of the child may be otherwise healthy;

the lungs themselves are in a normal state, and they can be easily expanded by the artificial introduction of air, or by other remedial measures when assistance is at hand. This imperfect expansion of the lungs is generally due to debility in the child, and it is especially a cause of death in weakly or immature children. But strong and healthy children may die from simple non-inflation of the lungs.

Assuming that in utero the child lives by what has been called "placental respiration," *i. e.*, a continuous supply of sufficiently oxygenated blood from the woman, another explanation may be offered. If anything should arrest the placental circulation during labor by interrupting the flow of blood to the child through the umbilical cord, this may cause its death before pulmonary inspiration can be established. The child is born asphyxiated, and this may explain the state of atelectasis. Every contraction of the uterus more or less interrupts placental respiration as it is above defined. The child lives inside the uterus by the placenta, and outside by the lungs. If the action of the placenta is destroyed before that of the lungs can be set up, this would explain the condition known under the name of atelectasis. (See a paper by Hofmann, Eulenberg's "Vierteljahr.," 1873, 1, p. 219.)

8. *Congenital disease.*—It has been elsewhere stated (p. 630, *ante*) that a child may be born laboring under such a degree of congenital disease as to render it incapable of living. The discovery of any of the foetal organs merely in a morbid condition amounts to nothing unless the disease has advanced to a degree which would be sufficient to account for death. There are, doubtless, many obscure affections, particularly of the brain, which are liable to destroy the life of a child without leaving any well-marked changes in the dead body. According to Dr. Burgess, apoplexy and asphyxia are common causes of death among newborn children. ("Med. Gaz.," vol. 26, p. 492; Henke's "Zeitschrift der S. A.," 1843, p. 67.) Probably diseases of the lungs are of the greatest importance in a medico-legal point of view; because, by directly affecting the lungs, they render it impossible for a child to live, or to survive its birth for a long period. These diseases in the foetal state are principally congestion, hepatization, tubercle, scirrhus, and oedema—the existence of any of which it is not difficult to discover. They render the structure of the lungs heavier than water, and thus prevent the organs from acquiring that buoyancy which in their healthier state they are known to possess. It is not common to find the lungs diseased throughout—a portion may be sufficiently healthy to allow of a partial performance of respiration.

Conclusions.—The following conclusions may be drawn from the preceding remarks:—

1. That a large number of illegitimate children, especially when immature, are born dead from *natural* causes.

2. That a child may die from exhaustion as the result of a protracted labor.

3. That if a child be prematurely born, or if it be small and weak even at the natural period, it may die from mere debility, or want of power in the constitution either to commence or to continue the act of breathing.

4. A child may die from loss of blood, owing to accidental rupture of the cord during delivery; it may even die from this cause after it has breathed.

5. That fatal bleeding is more likely to occur when the cord has been cut close to the abdomen than when it has been lacerated or cut at a distance from the navel.

6. That the division of the cord, whether by rupture or incision, without ligature, is by no means necessarily fatal to a healthy mature child.

7. That a child may die from accidental compression of the cord during delivery—the circulation between the mother and the child being thereby arrested before respiration has commenced.

8. That death may speedily follow birth from some malformation or defect, or from a defective condition of organs important to life.

9. That a child may die from congenital disease affecting the organs of respiration or the air passages.

CHAPTER LIII.

VIOLENT CAUSES OF DEATH.—SUFFOCATION.—DROWNING.—DEATH OF THE CHILD FROM COLD AND EXPOSURE.—STARVATION.—DEATH FROM IMMATURETY.—WOUNDS IN NEW-BORN CHILDREN.—FRACTURES OF THE SKULL, ACCIDENTAL AND CRIMINAL.—TWISTING OF THE NECK.—VIOLENCE IN SELF-DELIVERY.—POWER OF LOCOMOTION AND EXERTION IN FEMALES AFTER DELIVERY.

Violent causes of death.—In this chapter we have to consider those modes of death which are totally independent of the existence of congenital disease or other natural causes. In most cases of alleged child-murder, the body of the child bears about it the marks of physical injury, such as those which are indicative of strangulation, wounds, burns, and fractures. The marks of violence may be such as to leave no doubt that they were wilfully inflicted. In order to render either the woman or a confederate criminally responsible, it must be distinctly proved that the injuries were unlawfully inflicted on a *legally* living child, and that they were the cause of death. If the child has died after birth, from violence carelessly or ignorantly inflicted during birth or afterwards, or from culpable negligence, this will constitute a case of manslaughter. A question of medical responsibility may be raised under these circumstances, as where a medical man is charged with having caused the death of a child by gross ignorance and carelessness in the delivery of a woman. The following instance is reported by Chitty ("Med. Jur.," p. 416; also Archbold, p. 345): A man of the name of *Senior*, who, it appears, was an unlicensed medical practitioner, was tried for the manslaughter of an infant by injuries inflicted on it at its birth. The prisoner practised midwifery, and was called to attend the prosecutrix, who was taken in labor. The evidence showed that when

the head of the child presented, the prisoner, by some mismanagement, fractured and otherwise so injured the cranium, that the child died immediately *after* it was born. It was argued, in defence, that as the child was not born but *in ventre sa mere* at the time the wounds and injuries were inflicted, the prisoner could not be guilty of manslaughter. The judge, however, held that as the child was born *alive*, and had subsequently died from the violence, the case might be one of manslaughter. This opinion was afterwards confirmed by the other judges, and the prisoner was convicted and sentenced to imprisonment. From the decision in this case, it will be seen that if the prisoner had effectually destroyed the child before it was entirely born, he would not have been guilty of any crime!

Some of the causes of death in new-born children are unavoidable; others may be avoided by care and ordinary precautions. In some recent cases where the death of the child after its birth had been traced to culpable negligence on the part of the woman, our judges have directed a verdict of manslaughter, and have inflicted a severe punishment—ten years' penal servitude. (*Reg. v. Maynard*, Devon Aut. Ass., 1871; *Reg. v. Libbey*, Cornwall Aut. Ass., 1871; and *Reg. v. Sell*, Hereford Lent Ass., 1873.) In no case, however, have they dispensed with the proof that the child was *born* alive, either from medical evidence or from the confession of the woman.

Some general observations have been elsewhere made on the mode in which the dead body of a child in an alleged case of child-murder should be examined (*ante*, p. 599). A note of all marks of physical injury, however slight in appearance, may be of importance in the case. There are some forms of child-murder which are not necessarily attended with marks of violence; thus a child may be criminally destroyed by suffocation, drowning, exposure to cold, or privation of food. It may die under these circumstances, and its body may present no unusual appearance. These modes of destroying life will, therefore, first require consideration.

1. *Suffocation*.—This is a common cause of death in new-born children. A wet cloth may be placed over the child's mouth, or thrust into the cavity, either during birth or afterwards, and before or after the performance of respiration. To the latter case only could the term suffocation be strictly applied. In *Reg. v. Eley* (C. C. C., Aug. 1878), a case of alleged manslaughter, the child was found dead with a pocket handkerchief forcibly stuffed into its mouth. The state of the lungs showed that it had breathed, but it had not been heard to cry. It had died from suffocation, according to the medical evidence. The defence was that there was no proof that the child had been born alive. Notwithstanding the plain evidence of murder by the mode of death, the jury acquitted the prisoner. A child may be thus destroyed by being allowed to remain closely compressed under the bed-clothes after delivery or by its head being thrust into straw, feathers, ashes, and similar substances. Under these circumstances the child is not suffocated, but dies from the prevention of breathing. The appearances in the body in such cases are seldom sufficient to excite a suspicion of the cause of death, unless undue violence has been employed. There is commonly merely

lividity about the head and face, with slight congestion of the lungs. A careful examination of the mouth and throat should be made, as foreign substances are sometimes found in this situation, affording circumstantial evidence of the mode in which the suffocation has taken place. Thus wood, straw, feathers, ashes, tow, or a hard plug of linen may be, and in some cases have been, found blocking up the mouth and throat, drawn into these parts by aspiration when the mouth of a child has been covered with such substances. When a child is found dead under these circumstances a question will arise whether the ashes, dust, or other substances found in the air-passages have either been wilfully thrust into the mouth and throat, or accidentally drawn in by aspiration. Whether an accused person has placed the ashes in the mouth or buried the face of a child in them so that they might be thus drawn in, can make no difference in the nature of the crime. If the ashes are in large quantity, of large size, firmly impacted, and the lining membrane of the mouth presents signs of laceration or bruising, there can be no doubt that violence has been used. Aspiration would not explain facts of this kind. Again, the cinders and other substances may be found in the trachea and bronchi, into which parts they could not have been forced by manual violence. In all these cases the mouth and fauces require careful examination.

If a child has lived sufficiently long to be fed, it may be accidentally suffocated by the entrance of portions of solid food, such as the curd of milk, into the windpipe and air passages. A new-born child may be suffocated by having its head held over noxious vapors, such as the exhalations of a privy or of burning sulphur; and it is here necessary to remind a medical jurist that other highly poisonous vapors, *e. g.*, chloroform, or coal-gas, may be used by a criminal without leaving any indication in the body—except, possibly for a short time, that which may depend upon their peculiar odor. There are few of these cases of suffocation in which a positive medical opinion of the cause of death could be given, unless some circumstantial evidence were produced, and the witness were allowed to say whether the alleged facts were or were not sufficient to account for death. (“*Annales d’Hyg.*,” 1832, vol. 1, p. 691.)

On the other hand, if it be even clearly proved that death has been caused by suffocation, it must be remembered that a child may be accidentally suffocated, and the crime of murder falsely imputed. Dr. J. M. Duncan, quoting the observations of Dr. Buhl, states that obstruction of the air-passages by mucus and other matters is a frequent cause of death in new-born children. Among twenty-seven children dying in labor or shortly after birth, eleven died from obstruction of the air-passages with foreign matters. Eight were born dead, and of those which were alive at birth, none survived the first day. In ten of the cases the obstruction was produced by a greenish or greenish-brown slimy mass (meconium and mucus) filling the larynx and windpipe. In two of the cases, in which the child died during delivery, air was found in the lungs, and in only one of these, the air had been derived from the act of breathing during birth. (“*Edin. Monthly Med. Jour.*,” April, 1863, p. 924; also “*Med. Times and Gaz.*,” August 3, 1861, p. 117.) In Dr. Hicks’s case (p. 637, *ante*) the base of the tongue in a new-born child was so drawn

down by spasmodic action as to close the glottis by pressing backwards the epiglottis. The child was saved by simply raising the epiglottis, when air rushed in and breathing was established; but many children may be born under similar conditions when no assistance is at hand. Cases of this kind, however, rarely give rise to charges of child-murder, as no air is found in the lungs. A child might be killed during delivery by pressure applied to the chest; this might be such as not to produce any mark of violence. If the child had not breathed, there would be nothing to indicate the mode of death; if air had entered the lungs, then the usual appearances will be found in these organs (p. 606). In dealing with a case of this kind, it should be remembered that a child with its head born, but detained in the outlet by the size of its shoulders, might die from pressure exerted on the chest by the vagina. It might have breathed, but be born dead with the marks of suffocation about it.

There is another accidental cause of the death of a new-born child during delivery. The membranes or caul may be carried forward over the head and face, and the act of breathing thus mechanically prevented. If no assistance is at hand, the child, although born living, will die soon after birth in consequence of the prevention of respiration. If, when the dead body is found, the membranes are no longer there, the cause of the prevention of respiration would not be apparent. The child, although born living, would probably be pronounced to have been born dead. ("Mel. Times and Gaz.," January, 1863, p. 126.) The delivery of a child with a mask or caul around its head is not an unfrequent occurrence. In June, 1862, Mr. Blenkinsop, of Warwick, communicated to me a case in which a mature and healthy child so born was allowed to perish by those who had access to it. The caul was simply not removed, so that breathing could not be set up. The lungs contained no air. There was congestion of the brain and lividity of the body, but no mark of violence. There was some evidence that the child had been born living, and that the cause of death was the prevention of respiration by omission to do that which was necessary; but as the medical evidence showed that the child had not breathed, the coroner held that it had never had any (legal) existence, and that there was no ground for further investigation. Dr. Hunter, who was well aware of the risk to which a woman might be thus exposed, observes in relation to this state of things: "When a woman is delivered by herself, a strong child may be born perfectly alive, and die in a very few minutes for want of breath, either by being on its face in a pool formed by the natural discharges, or upon wet clothes; or by the wet things over it collapsing and excluding air, or being drawn close to its mouth and nose by the suction of breathing. An unhappy woman delivered by herself, distracted in her mind and exhausted in her body, will not have strength or recollection enough to fly instantly to the relief of her child." (Op. cit., p. 35.) It may be added that a primiparous woman may faint, or be wholly unconscious of her situation; or, if conscious, she may be ignorant of the necessity of removing the child, and thus it may be suffocated without her having been intentionally accessory to its death. In such cases, however, there should be no marks of violence on the body, or, if present, they should be of such a nature and in such a situation as to be readily explicable on the supposition of an acci-

dental origin. (See case by Dr. Dohow (Horn's "Vierteljahr.," 1864, 2, p. 123.)

An infant is easily destroyed by suffocation. It is a frequent form of infanticide. The late M. Tardieu stated that he had had the cases of 132 new-born children to examine, and in 72 of them he detected clear evidence of death by suffocation. ("Annales d'Hyg.," 1855, vol. 2, p. 372.) If the mouth and nostrils of a child are kept covered for a few minutes, by the face being closely wrapped in clothes, asphyxia may come on without this being indicated by convulsions or any other marked symptoms (see p. 484, *ante*). A suspicion of murder may arise in such cases; but the absence of marks of violence, with an explanation of the circumstances, will rarely allow the case to be carried beyond an inquest. Sometimes the body is found maltreated, with severe fractures or contusions on the skull, and marks of strangulation on the neck; concealed in a feather-bed or privy, or cut up and burnt. This kind of violence may properly excite a suspicion of murder, and lead to the belief that the allegation of death from accidental suffocation is a mere pretence. This, however, is purely a question for a jury, and not for a medical witness. Unless the case is of a glaring nature, the violence is considered to have been employed for the purpose of rather concealing the birth of a child than of destroying it. In the present day these cases of death from accidental suffocation, when properly investigated, can never involve an innocent woman in a charge of murder, although the facts may show in many instances that the death of the child was really due to great imprudence, gross neglect, or culpable indifference on her part. When culpable neglect or reckless indifference to the life of a new-born child has been proved against a woman charged with murder, a verdict of manslaughter has been returned.

The appearances in the body in cases of death from suffocation have been elsewhere described, in reference to adults (p. 477); they are similar to new-born children, provided respiration has been fully performed. M. Tardieu attaches great importance to the discovery of subpleural ecchymoses in the lungs of children: he has also noticed small effusions of blood on the surface and in the substance of the thymus gland. ("Ann. d'Hyg.," 1855, vol. 2, p. 379.) If the lungs float on water, as the result of breathing, then the appearances described will be met with: but it is worthy of remark that in three instances M. Tardieu met with similar appearances in children whose lungs had not received air, and sank when placed on water! They were children prematurely born, and under conditions which prevented full vital development. One born in the Hospital of Riboisière uttered several cries, but in spite of this, the lungs contained no air. The subpleural ecchymoses met with in children under these circumstances, are ascribed by M. Tardieu to the efforts made to breathe after birth (*loc. cit.*). Partial emphysema of the lungs is occasionally observed.

Some remarks have been elsewhere made on the evidence derivable from the presence of subpleural ecchymoses (p. 477). In death from suffocation they are not always found, and in other forms of asphyxia they have been occasionally seen, so that they cannot be considered as characteristic of any one form. In May, 1872, Dr. Moore, of Lancaster,

consulted me on the following case. A servant girl had given birth to a healthy child. This child was found alive about a quarter of an hour afterwards in a privy, and it lived a few minutes after the discovery. Its jaw was broken, its cheek torn, and the mouth contained ashes, some of which were found in the back part of the throat. The body was blanched, and there had evidently been a great loss of blood from the wounds and the torn umbilical cord. There was no engorgement of the lungs, nor were there any subpleural ecchymoses. The lining membrane of the trachea was stained with ashes, and a small cinder was found in the left bronchus. In this case there was no question respecting live birth, as the child was living when found—but What was the cause of death, and was this accidental, or the result of violence wilfully applied after birth? In the opinion of Dr. Moore, the mouth of the child had been forcibly torn open and filled with ashes in order to suffocate it; these ashes might have been then drawn by aspiration into the air-passages, and death caused partly by suffocation and partly by hemorrhage from the wounds, the child's body being bloodless. The condition of the lungs was not inconsistent with death from suffocation. For some remarks on death from suffocation in child-murder, with reports of cases, see a paper by M. Séverin Causé, "*Ann. d'Hyg.*," 1869, 2, 122, 443.

2. *Drowning*.—The fact of drowning cannot be verified by any appearances on the body of a child which has *not* breathed. Thus, if a woman caused herself to be delivered in a bath, and the child was forcibly retained under water (a case which is said to have occurred), it would of course die; but no evidence of the mode of death would be found in the body. After respiration, the signs of drowning will be the same as those met with in the adult. (See p. 420, *ante*.) The main question for a witness to decide will be, whether the child was put into the water living or dead. Infanticide by drowning is by no means common; the child is generally suffocated, strangled, or destroyed in other ways, and its body is then thrown into water in order to conceal the real manner of its death. The fact of the dead body of an infant being found in water must not allow a witness to be thrown off his guard: although a verdict of "found drowned" is so commonly returned in these cases, the body should be carefully inspected in order to determine what was really the cause of death. All marks of violence on the bodies of children that have died by drowning, should be such as to have resulted from accidental causes. The throat and air-passages should be particularly examined.

It is not necessary that the *whole* of the body of a child should be submerged, in order that it may be destroyed by drowning: the mere immersion of the head in water or the covering of the mouth by liquid, will suffice to produce the usual effects of asphyxia. The outlets of the ears and the air-passages should be examined for foreign substances which may be deposited in them. New-born children may be drowned or suffocated by being thrown into mud or into the soil of a privy. Sometimes the child is destroyed by other means, and its body is thus disposed of for the purpose of concealment. Should there be a large quantity of liquid present, the phenomena are those of drowning. The liquid portion of the soil abounding in sulphide of ammonium may be found, if the child was thrown in living, in the air-passages, gullet or stomach. The mere

discovery of soil in the mouth would not suffice to show that the child was living when immersed ; but the presence of foreign substances, such as dirt, straw, or ashes, in the air-passages, gullet and stomach, has usually been taken as a medical proof that the child was living when immersed, and that the solid substances had been drawn into the passages by aspiration or by the act of swallowing.

On these occasions the defence may be : 1. That the child was born dead, and that the body was thrown in for concealment ; but the medical evidence may show that it had breathed, and had probably been born living. 2. It may be alleged that the child breathed for a few moments after birth,—had then died, and that the woman had attempted to conceal the dead body. A medical witness may be here asked, whether a woman could have had power to convey the body to the place—a point which must, as a general rule, be conceded. 3. It is most commonly urged, that the woman being compelled to go to the privy, was there *delivered unconsciously* or unexpectedly ; that her waters had broken, and that she had no idea of anything more having happened ; or that the child had dropped from her, and was either suffocated or prevented from breathing. (“Med. Times and Gaz.,” Dec. 21, 1861, p. 646.) All these circumstances may readily occur, but on the other hand, such statements may be inconsistent with some of the medical facts. (See a case by M. Adelon, “Ann. d’Hyg.,” 1855, vol. 2, p. 453 ; also Casper’s “Klinische Novellen,” 1863, p. 585.) Thus the head or the limbs of a child may be found to have been separated or divided by some cutting instrument, or a cord or other ligature may be found tightly bound around its neck, or there may be a tightly-fitting plug in the throat. Then, again, the body may be entire, but the umbilical cord may be *cleanly cut*. This would tend to set aside the explanation of the child having accidentally dropped from the female : because in such an accident the cord should always be found *ruptured*. The practitioner should make a careful examination of the divided ends of the cord by the aid of a lens, or a rupture may be mistaken for a section with a sharp instrument. Mr. Higginson, of Liverpool, has published a case of some interest in this point of view. The child fell from the mother, and the cord broke spontaneously. “The torn ends were,” he states, “nearly as sharp-edged and flat as if cut.” (“Med. Gaz.,” vol. 48, p. 985.) This case goes to prove that a careless or hasty examination of the ends of the cord may lead to a serious mistake. When the cord is lacerated, this will be, *cæteris paribus*, in favor of the woman’s statement as to the mode in which her delivery occurred.

Drowning may be the result of accident from sudden delivery. A woman in an advanced state of pregnancy, while sitting on a chamber vessel, was suddenly delivered. The child fell into the fluids in the vessel, and before assistance could be rendered, it was dead. Whether, in any instance, the *drowning* of a child was accidental or criminal, must be a question for a jury to determine from all the facts laid before them. The situation in which the body of an infant is found, may be consistent with the supposition of accident. Thus a child may be accidentally drowned by its mouth falling into a pool of the discharges during delivery, although this would be rather a case of suffocation.

The throat, windpipe, and stomach of the child should always be examined on these occasions, as mud, sticks, straw, weeds, or other substances may be found in these parts, indicating, according to circumstances, that the child had been put into the water living, and that it had been drowned in a particular pond or vessel. In a charge delivered by the Recorder at the Central Criminal Court (Oct. 27, 1873) he is reported to have made these observations to the Grand Jury in reference to the finding of the body of a new-born child in a pail of water. "The law of infanticide in its present state was by no means satisfactory, and the consequence was, he feared, that many a crime of this kind was committed with perfect impunity. In the case under consideration, there was nothing to show that, at the time of its death, the child had an existence perfectly independent of the mother, and unless the Grand Jury were satisfied to the contrary it seemed to him that the charge of murder could not be entertained, although they might probably be of opinion, from the surrounding circumstances, that the infant was dropped into a pail of water with an intent to cause death." A woman aware of her condition, and not having the intention to destroy her child, would hardly resort to this method of self-delivery. Such an act would justify a verdict of manslaughter.

3. *Cold and Exposure*.—A new-born child may be easily destroyed by simply exposing it uncovered, or but slightly covered, to a cold atmosphere. In a case of this kind there may be no marks of violence on the body, or these may be slight and evidently of accidental origin. In death from cold the only appearance occasionally met with has been congestion of the brain, with or without serous effusions in the ventricles. (See COLD, p. 528, *ante*.) The evidence in these cases must be purely circumstantial. The medical witness may have to consider how far the situation in which the body was found,—the kind of exposure, and the temperature of the air, would suffice to account for death from the alleged cause. There is no doubt that a new-born child may soon perish from exposure to a low temperature, and that warm clothing is required for the preservation of its life. An inspection of the body should never be omitted on these occasions, because it might turn out that there was some latent cause of natural death which would at once do away with the charge of murder. Admitting that the child had died from cold, it becomes necessary to inquire whether it was exposed with a malicious intention that it should thus perish. Unless wilful malice be made out, the accused cannot be convicted of murder, and unless culpable neglect is proved, she cannot be convicted of manslaughter. In general, women do not expose their children for the purpose of destroying them, but for the purpose of abandoning them; hence it is rare to hear of convictions for child-murder where cold was the cause of death, although some medical jurists have called this infanticide by *omission*.

4. *Starvation*.—A new-born child kept long without food will die, and no evidence of the fact may be derivable from an examination of the body. There may be no marks of violence externally, nor any pathological changes internally, to account for death. This is a rare form of murder, except as it may be accidentally combined with exposure to cold. In order to convict the mother, it is necessary to show

that the child was wilfully kept without food, with the criminal design of destroying it. Mere neglect or imprudence will not make the case infanticide. The only appearance likely to be found on an examination of the body would be complete emptiness of the alimentary canal. Without corroborative circumstantial evidence, this would not suffice to establish the cause of death: a medical witness could only form a probable conjecture on the point. In a suspected case of this kind, the contents of the stomach should be tested for farinaceous and other kinds of food.

5. *Immaturity in cases of abortion.*—From the case of *Reg. v. West* (Nottingham Lent Ass., 1848), it would appear that if by the perpetration of abortion, or the criminal induction of premature labor, a child be born living at so early a period of uterine life that it dies merely from *immaturity*, the person causing the abortion, or leading to the premature birth, may be tried on the charge of murder. A midwife was alleged to have perpetrated abortion on a female who was between the fifth and sixth months of pregnancy. The child was born living, but died five hours after its birth. There was no violence offered to it; and its death appeared to be due entirely to its immaturity. The prisoner was acquitted, apparently on the ground that abortion might have arisen from other causes. In a case of this kind it must be clearly proved that the child survived its birth.

Among those causes of *violent* death which leave on the body of the child certain marks or appearances indicative of the cause, may be mentioned wounds, strangulation, and poisoning.

6. *Wounds.*—Probably this is one of the most frequent causes of death in cases of child-murder. Wounds may, however, be found on the body of a child who has died from some other cause. The principal questions which a medical witness has to answer are: 1. Whether the wounds were inflicted on the body of the child before or after death. 2. Whether they were sufficient to account for death; and 3. Whether they resulted from accident or criminal design. The child may have been destroyed by *burning*, and evidence must then be sought for by an examination of the state of the skin. All these questions have been fully considered in treating the subject of WOUNDS and BURNS, and they therefore do not require any special notice in this place. Incised wounds found on the bodies of new-born children may be referred to the use of a knife or scissors by the prisoner, in attempting to sever the navel-string, and they may therefore be due to accident. This point should not be forgotten, for a wound even of a severe kind might be thus accidentally inflicted. In such cases we should always expect to find the navel-string *cut*, and not lacerated. The end of it may, for the purpose of examination, be stretched out on a white card. This will in general suffice to show whether it has been cut or torn. Wounds, however slight, should not be overlooked: minute punctures or incisions externally may correspond to deep-seated injury of vital organs. The spinal marrow is said to have been wounded by needles or stilettoes introduced between the vertebræ, the skin having been drawn down before the wound was inflicted, in order to give to it a valvular character, and to render it apparently superficial.

The brain is also said to have been wounded, by similar weapons, either through the nose or the thinner parts of the skull (the fontanelles). Hence, in examining the head of a new-born child to determine the cause of death, it is always necessary to observe the state of the fontanelles. Children have been destroyed by small punctures made through these membranous coverings. Fatal wounds of the brain have been thereby produced. ("Ann. d'Hyg.," Nov. 1878, p. 498.)

In some instances the body of a child is found cut to pieces, and the allegation in defence may be that the child was still-born, and the body thus treated merely for the purpose of concealment. Dr. Toulmouche has reported a case of this kind, which was the subject of a trial in France in 1852. As the woman had not destroyed the lungs, experiments on these organs gave satisfactory results of perfect respiration. The cavities of the heart and great vessels were empty: the body was generally drained of blood, and the skin throughout very pale. This led to the inference that the mutilations must have been inflicted while the child was living; and as all the parts were healthy, and no natural cause of death was apparent, Dr. Toulmouche ascribed the death of the child to the wounds. The woman was convicted, and condemned to twenty years' confinement in the galleys. ("Ann. d'Hyg.," 1853, vol. 2, p. 200.) In this country she would probably have escaped under a verdict of "concealment of birth," and have been sentenced to a year's imprisonment.

Bleeding from the umbilical cord.—A woman may be delivered in secret; she may divide the umbilical cord and leave it untied. In this case a healthy child with a vigorous circulation may bleed to death unless a ligature is applied to arrest the flow of blood. Most women are aware of the necessity of this operation soon after the cord has been cut—the escape of blood from the cord would at once indicate what was required in order to arrest the bleeding. A woman having the power to tie the cord, and neglecting to do this might be charged with infanticide from culpable negligence. A case of this kind was tried at the Cardiff Winter Assizes (Feb. 1880), (*Reg. v. James*). The prisoner, a widow, was seized with labor-pains; she would not allow her servant to fetch a midwife who lived near, saying it was too late, and the child was born soon afterwards. She then cut the umbilical cord with scissors, but did nothing further, and the child was put on the bed when it uttered a faint cry. After a time she told the servant to take the child away. It was then dead and cold. It had obviously died from excessive bleeding. The medical evidence showed that the child was mature, and had been born alive, and the non-tying of the cord was the probable cause of death. It was proved further that the woman had provided no clothes for the child, and had refused the services of a midwife who lived near. She had deliberately cut the umbilical cord and left it untied. Under these circumstances she was charged with manslaughter, and with causing the child's death through culpable negligence; but the jury found that there was no culpable negligence, and she was acquitted.

Injuries to the head.—It has been elsewhere stated that during a protracted delivery, there is formed on the head of a child a tumor containing either serum, blood, or a mixture of the two. If a woman has been secretly delivered, non-professional persons may ascribe a tumor of this

kind to violence, whereas it may really have been produced by natural causes. The tumor is generally situated on one of the parietal bones, its situation depending on that part of the head which presents during delivery. After the discharge of the waters, the scalp is firmly compressed by the mouth of the uterus, and subsequently by the os externum. This pressure interferes with the circulation through the skin, and causes the compressed portion of the scalp to swell. In the simplest form of this tumor, serum only is found in the swollen part: occasionally this is mixed with blood, and there are small ecchymoses of the scalp, as well as of the pericranium and skull, but there is generally no injury to the bones, nor is there any laceration of the skin externally. In other cases blood is found effused in the tumor either under the scalp, the membrane covering the skull (pericranium), or within the skull itself. The term *cephalæmatoma*, or *caput succedaneum*, is applied to a tumor which has this natural origin (p. 634, *ante*). The sanguineous is more likely to be confounded with the effects of violence than the serous tumor; but it may be identified by the scalp being always uninjured, although it may present redness and lividity. Violence from blows or falls, which would produce bloody effusions beneath the scalp, or within the skull, would in general be indicated by injury to the skin or by fracture of the bones.

The only injuries to the head which require to be specially considered in relation to infanticide, are *fractures of the skull*; and here the question to which we may chiefly confine our attention is, whether the fracture arose from accident or criminal violence. The rules for determining whether these injuries were inflicted during life or after death have been elsewhere considered. (See WOUNDS, pp. 263–393.) Although it has been a matter of frequent observation that great violence may be done to the head of a child during parturition without necessarily giving rise to fracture, yet it is placed beyond all doubt that such an injury may occur by the expulsive efforts of the uterus in forcing the head of a child against the bones of the pelvis. Even the violent compression which the head sometimes experiences in passing the mouth of the uterus, may suffice for the production of fracture. (See “Edin. Med. and Surg. Jour.,” vol. 26, p. 75.)

It was formerly supposed that fractures of the skull in new-born children were always indicative of criminal violence; but cases which have occurred in obstetric practice have established the certainty of their accidental occurrence. These accidental fractures, it is to be observed, are generally slight; they commonly amount merely to fissures in the bones, beginning at the sutures and extending downwards for about an inch or less into the body of the bone. According to Dr. Weber, the frontal and parietal bones are the only bones liable to be fissured or fractured by the action of the uterus during delivery; and in the greater number of cases reported, the parietal bones only have presented marks of fracture. The possible occurrence of an injury of this kind as the result of uterine action, has been strained in several cases of child-murder, to explain the origin of fractures which could not fairly or reasonably be assigned to such an accident. A case was tried at Glasgow, in April, 1852 (case of *Ann Irvin*), in which there was no doubt, from the state of the lungs, that the child had fully breathed, and there was

violence to the head which satisfactorily accounted for its death. The whole of the right side of the head was deeply ecchymosed, and there was a large quantity of coagulated blood lying beneath the scalp. In the centre of the right parietal bone there was a fracture extending across the vertex for fully four inches, and involving a part of the parietal bone on the opposite side; it was in a continuous even line, not radiated and not depressed. The pericranium, bones, and soft parts in the track of the fracture were deeply ecchymosed, while on the surface of the brain, particularly on the right side, there was a copious effusion of clotted blood. It was impossible to refer severe injuries of this kind to the action of the uterus in delivery, or to violence applied after death. The prisoner alleged that the child was still-born. (See "*Edin. Monthly Jour.*," June, 1852.)

Accidental fractures and effusions of blood which are caused by uterine action, may be in general recognized by their slight extent. In cases of murder by violence to the head, the injuries are commonly much more severe; the bones are driven in, the brain protrudes, and the scalp is extensively lacerated. Such severe injuries as these cannot be ascribed to the action of the uterus in parturition. Here, however, it may be fairly urged, that the woman was unexpectedly seized with labor, that the child was expelled suddenly by the violent efforts of the uterus, and that the injuries might have arisen from its head coming in contact with some hard surface—as a floor or pavement. It must be admitted that a woman may be thus suddenly and unexpectedly delivered while in the erect posture, although this is not common among primiparous women; and that injuries may be thus accidentally produced on the head of a child.

A woman is often unable to distinguish the sense of fulness produced by the descent of a child, from the feeling which leads her to suppose that she is about to have an evacuation; and thus it is dangerous, when a labor has advanced, to allow a woman to yield to this feeling, for there is nothing more probable than that the child will be suddenly born. Mr. Rankin, of Carlisle, has reported two cases of this description, where there could not be the slightest suspicion of criminality. In one, a primipara, the child was actually born under these circumstances, but its life was fortunately saved; had there been no other convenience than a privy, it must have been inevitably lost. In the second, although a case of third pregnancy, the female was equally deceived by her sensations. ("*Edin. Month. Jour.*," Jan. 1846, p. 11.) It is true that this alleged mistaken sensation forms a frequent and specious defence on charges of child-murder; but still a medical jurist is bound to admit that an accident which occurs to women of the middle class may also occur to women of a lower class without necessarily implying guilt.

The following case shows that a fracture of the skull of a child may occur when a woman is delivered in the erect posture. In this instance there was merely the appearance of a bruise on the head, and the navel-string was ruptured (not cut) three inches from the navel. The child did not suffer from the fall, and continued well until six days after its birth, when it was seized with convulsions and died. A fissure of about

an inch and a half in length was found in the upper part of the left parietal bone. A clot of blood was found in this situation between the dura mater and bone, and there was congestion of the vessels of the membranes; with this exception there was no morbid appearance in the body. ("Association Journal," Oct. 14, 1853, p. 901.) Dr. Porter Smith, of Bath, communicated to me a case which occurred in November, 1856, in which the facts were similar to those above related. In consequence of the concealment of the body, however, the mother was charged with murder. The right parietal bone was fractured, and there was effusion of blood internally, but there was no mark of external violence. The cord had been ruptured at a distance of two-and-a-half inches from the navel. The stomach of the child contained the usual albuminous and mucous matters of the foetal state, without any appearance of food. The lungs contained air, and were highly crepitant; the foramen ovale and the ductus arteriosus were in their foetal condition. The child had probably been drowned in the discharges from want of assistance at the time of birth. The woman, who admitted that the child had fallen from her suddenly, was acquitted. Dr. Olshausen has published four cases of sudden delivery, in each of which the child dropped from the woman, and in two of them there were fissures in the parietal bones. The children recovered from the effects of the accidents. ("Med. Times and Gaz.," Sept. 1860; "Am. Jour. Med. Sci.," Jan. 1861, p. 279.) Other cases of rapid delivery in the erect posture are reported in the "Lancet" (Jan. 5, 1861, p. 13). In these there was no injury to the child, although in one case the delivery took place on the deck of a vessel.

A medical witness would find no difficulty in determining the probability of this explanation of the accidental origin of such fractures, if he were made acquainted with all the facts connected with the delivery. But the acquisition of this knowledge must be accidental; and it will in general be out of his power to obtain it. When the fractures are accompanied by cuts, punctures, or lacerations of the scalp or face, although their production might be accounted for by an alleged fall during parturition, the cause of these wounds would still remain to be explained. In fractures of the bones of the head in new-born children, the presence of effusions of blood on the outside of the skull, or on the membranes within, is one of the most common appearances. Effusions of blood beneath the skin of the scalp are by no means uncommon in new-born children, and are not necessarily indicative of criminal violence. Each case, however, must be decided by the circumstances attending it. Effusions on the membranes and in the substance of the brain are generally the result of great violence to the head.

Twisting of the neck.—Children are sometimes destroyed in the act of birth by the neck being forcibly twisted, whereby a displacement of cervical vertebræ, with injury to the spinal marrow, may occur, and destroy life. Such injuries are immediately discovered by an examination of the body. It should be remembered that the neck of a child is very short, and that it always possesses considerable mobility.

Destruction by fire.—New-born children are sometimes destroyed by placing their bodies in a fierce fire. The result of this is that only

charred flesh with white fragments of burnt bones may be found. In one case elsewhere reported, the body of a child was found in a sauce-pan boiled. It was here a question whether it had been put in living or dead (see p. 411).

Violence in self-delivery.—When the marks of violence found on the head, neck, or body of a child cannot be easily referred to uterine action or to an accidental fall, it is common to ascribe them to the efforts made by a woman in her attempts to deliver herself—the destruction of the child being an accidental result of these efforts. A medical opinion in such cases must depend upon the nature, situation, and extent of the injuries ; and each case must be therefore decided by the circumstances attending it. A medical witness, however, should always be prepared to allow that a woman at the time of her delivery, owing to pain and anxiety, may be deprived of all judgment, and may destroy her offspring without being conscious of what she is doing. It is therefore a sound principle of law that mere appearances of violence on a child's body are not *per se* sufficient, unless there is some evidence to show that the violence was knowingly and intentionally inflicted, or the appearances are of such a kind as of themselves to indicate intentional murder. (Alison.) But, judging from the verdicts returned in cases which have hitherto occurred, it would be very difficult to suggest any appearances which would be considered by a jury sufficient to indicate murderous violence.

Power of exertion in recently-delivered women.—On these occasions, a witness will often find himself questioned respecting the strength or capability for exertion, evinced by the lower class of women shortly after child-birth. Dr. Alison remarks that many respectable medical practitioners, judging only from what they have observed among the higher ranks, are liable to be led into an erroneous opinion, which may affect their evidence. He mentions a case, in which a woman accused of child-murder walked a distance of twenty-eight miles in a single day, with her child on her back, two or three days after her delivery. (Case of *Anderson*, Aberdeen Spring Circ., 1829.) Instances have even occurred in which women have walked six and eight miles, on the very day of their delivery, without sensible inconvenience. (“Criminal Law,” p. 161.) In one case (*Smith*, Ayr Spring Circ., 1824), the woman was engaged in reaping,—she retired to a little distance, effected her delivery by herself, and went on with work for the remainder of the day, appearing only a little thinner and paler than usual. In *Reg. v. Stowler* (Wells Aut. Ass., 1865), two witnesses proved that the prisoner, who was tried for the murder of her child, was at work with them in a field about 800 yards from a pond in which the body was afterwards found. They left the prisoner weeding, returned in about an hour, and she was not then in the field. After a time she returned, sat on a bank, and then resumed her work. The witnesses noticed that, on her return, there was a great difference in her appearance. In this short interval she had been delivered, had disposed of the body of the child, and resumed her work, as if nothing had happened. A firm resolution, with a desire to conceal her shame, may enable a woman, immediately after her delivery, to perform acts connected with the disposal of the body of her child which, from ordinary experience, might appear to be far beyond her strength.

In *Reg. v. May* (Court of Exchequer, May, 1857), for concealment of birth, it was proved that the prisoner, a domestic servant, had been sent to market with some poultry. On her return, she asked the boy who drove the cart to stop. He did so: she got out and went to a recess in the hedge by the side of the road, and in five minutes she was observed following the cart, and she walked home a distance of a mile and a half. She went about her usual work on that and the following day. She had been delivered of a child in the recess, and it was subsequently found there. One witness heard it cry, but it soon died.

Conclusions.—The conclusions to be derived from the contents of this chapter are :—

1. That a new-born child may die from violent causes of an accidental nature.

2. That some forms of violent death are not necessarily attended with external signs indicative of violence.

3. That a child may be accidentally suffocated during delivery.

4. That the usual marks of death from suffocation or drowning are not apparent, except in the bodies of children which have breathed.

5. That the state of the umbilical cord may often furnish important evidence.

6. That a new-born child may speedily die from exposure to cold or from want of food.

7. That slight fractures of the bones of the cranium may arise from the action of the uterus on the head of the child during delivery.

8. That women may be unexpectedly delivered while in an erect posture; the umbilical cord is under these circumstances sometimes ruptured, and the child may sustain injury by the fall.

9. That the violence found on the body of a child may be sometimes referred to attempts innocently made by a woman to aid her delivery.

10. That some women recently delivered may have strength to exert themselves and walk great distances.

CHAPTER LIV.

DEATH OF THE CHILD FROM STRANGULATION.—STRANGULATION BY THE NAVEL-STRING.—ACCIDENTAL MARKS RESEMBLING THOSE OF STRANGULATION.—CONSTRICTION BEFORE AND AFTER DEATH.—BEFORE AND AFTER BREATHING.—BEFORE AND AFTER THE SEVERANCE OF THE NAVEL STRING.—EXAMINATION OF WOMEN.—MEDICAL RESPONSIBILITY.

AMONG the forms of violent death which are generally attended with appearances indicative of criminal design are the following :—

7. *Strangulation.*—The destruction of a new-born child by strangulation is not an unfrequent form of child-murder; and here a medical jurist has to encounter the difficulty, that the strangulation may have been accidentally produced during delivery by a twisting of the umbili-

cal cord round the neck. We must not hastily conclude, from the red and swollen appearance of the head and face of a child when found dead, that it has been destroyed by strangulation. There is no doubt that errors were formerly made with respect to this appearance; for Dr. Hunter observes: "When a child's head or face looks swollen, and is very red or black, the vulgar, because hanged people look so, are apt to conclude that it must have been strangled. But those who are in the practice of midwifery, know that there is nothing more common in natural births, and that the swelling and deep color go gradually off if the child live but a few days. This appearance is particularly observable in those cases in which the navel-string happens to gird the child's neck, and where its head happens to be born some time before its body." (Op. cit., p. 27.)

Strangulation by the *navel string* can of course refer to those cases only in which it becomes firmly twisted round the neck *after* the child has breathed. This is rather a rare occurrence, because under these circumstances death more commonly takes place by compression of the cord, and by the consequent arrest of circulation before the act of breathing is performed. The only internal appearance met with in death from this cause is a congested state of the cerebral vessels. The presence of ecchymosis on the scalp, as well as of lividity of the face, is very common in new-born children when the labor has been tedious and difficult; and therefore, unless there were some distinct marks of pressure about the neck, with a protrusion of the tongue, such appearances would not justify a suspicion of death from strangulation.

It has been supposed that the strangulation produced by the wilful application of any extraneous constricting force to the neck would be known from the accidental strangulation caused by the cord, by the fact that in the former case there would be a livid or ecchymosed mark or depression on the neck, while in the latter there would not. Severe violence to the neck of a new-born child may produce in the seat of constriction not only ecchymosis but a laceration of the skin, muscles, and windpipe; but these appearances are not always present even in homicidal strangulation. In April, 1861, Dr. Evans, of Sunderland, communicated to me the particulars of the case of a new-born child which had been destroyed by strangulation. Great violence had been used, but there was no trace of discoloration in the course of the ligature, or of ecchymosis in the tissues beneath. The muscles compressed were very dark in color. In most cases when a ligature is applied to the neck during life the skin above and below it becomes much swollen and presents an œdematous character. This indicates an application of violence when there is still some vital power in the body of the child.

The navel-string itself may be used as a means of constriction, and the mark or depression may sometimes present an appearance of ecchymosis. Among various cases which might be quoted in support of this statement, is the following reported by Mr. Foster. In April, 1846, he was summoned to attend a lady in labor with her first child. The labor was of a lingering kind, owing to the size of the head; and the child came into the world dead. The navel-string was found coiled three times round the neck, passing under the right armpit; and upon removing it

three parallel discolored depressions were distinctly evident. These extended completely round the neck, and corresponded to the course taken by the coils. The child appeared as if it had been strangled. ("Med. Gaz.," vol. 37, p. 485). Had this child been born secretly, this state of the neck might have created a strong suspicion of homicidal violence. Strangulation after birth could not, however, have been alleged, because there would have been no proof of respiration. When a blue mark is found on the neck of a child whose lungs retain their foetal characters, it is fair to presume, *cæteris paribus*, that it has been accidentally occasioned by the twisting of the umbilical cord during delivery. Mr. Price has communicated to the same journal the account of a case in which the cord, which was short, was so tightly twisted around the neck of a child, that he was compelled to divide it before delivery could be accomplished. There was in this instance a deep groove formed on the neck, conveying the impression to himself and a medical friend that, in the absence of any knowledge of the facts, they would have been prepared to say that the child had been wilfully strangled by a rope. ("Med. Gaz.," vol. 38, p. 40.) A diagnosis might have been formed, as in the preceding case, by examining the state of the lungs. Dr. Mutter met with a case in which a child was born dead, and the cord was tightly twisted around its neck; when removed, the neck exhibited a livid circle of a finger's breadth, smooth and shining; but on cutting into this mark, no ecchymosis was found. ("North. Journ. Med.," Jan. 1845, p. 190.) In *Reg. v. Martin* (Lewes Lent Ass., 1860), the material question was, whether a mark round the neck had been caused accidentally by the navel-string; this was denied by the medical witness. A similar question also arose in another important case—*Reg. v. Pyne* (Gloucester Winter Ass., 1858).

Dr. Williamson, of Leith, has directed attention to an important fact connected with the state of the lungs in a new-born child, and the medical opinions which may be expressed from their condition as furnishing evidence of live birth. Referring to Mr. Price's case, in which the cord was tightly twisted round the neck of the child, he states that in similar cases which have occurred to himself, the child has breathed immediately on the birth of the head; but owing to the shortness of the cord, the child would have been strangled and born dead unless he had divided it. Thus, then, a child might die apparently strangled, and not be born alive, although it might have so breathed during birth that the lungs would present the usual characters of respiration. If the circumstances were not known, a medical man might be led to say that the child had been born alive, and had been destroyed by strangulation. ("Edin. Med. Jour.," Feb. 1858, p. 714.) The proof of respiration, as it has been elsewhere stated, is, however, not necessarily a proof of live birth. From these cases it will be perceived that ecchymosis in the depression on the neck, furnishes no distinction between constriction produced by criminal means, and that which may result accidentally from the navel-string. In the following case ("Ann. d'Hyg.," 1841, vol. 1, p. 127), a woman charged with the murder of her child by strangulation appears to have been unjustly condemned. The child had fully and perfectly breathed: the lungs weighed one thousand grains, and when di-

vided, every portion floated on water, even after firm compression. There was a circular depression on the neck, which was superficially ecchymosed in some parts. From an investigation of the facts, this appeared to have been a case in which a mark on the neck was accidentally produced by the umbilical cord, during attempts at self-delivery on the part of the woman: she was nevertheless convicted and condemned to a severe punishment, chiefly from the opinion expressed by two medical witnesses, that a soft and yielding substance like the umbilical cord could *not* produce a depression and ecchymosis on the neck of a child during birth. They attributed the mark to the wilful application of a ligature like a garter; but the experiments of Dr. Négrier clearly show that the umbilical cord has sufficient strength to produce a mark, and with it a fatal constriction. (“Ann. d’Hyg.,” 1841, loc. cit.)

In the same volume of the “Annales d’Hygiène” (at p. 428), will be found the report of another case, suggesting many important reflections in regard to the medical jurisprudence of infanticide. In this instance the navel-string and the membranes were actually used by a woman as a means of strangulation; the child had not breathed, but was by this act of violence prevented from breathing. There was superficial ecchymosis on each side over the muscles of the neck. The defence was, that the child was born with the cord around its neck, and that it was from this circumstance accidentally strangled; but the medical evidence tended to show that the cord had been violently stretched, and employed as a means of strangulation. The child had *not breathed*, and the medical witnesses considered that it had been born dead, owing to the violence used by the woman. The cause of death here was certainly not strangulation, but arrested circulation. In the mean time, the case proves that ecchymosis (a blue mark) may be the result of violent constriction produced by the navel-string. A case occurred to Mr. M’Cann in September, 1838, in which the navel-string, which was of its full length, had been also used as the means of strangulation. It was twisted once round the neck, passed under the left arm, over the shoulders, and round the neck again, forming a noose or knot, which, pressing upon the throat, must have caused strangulation, as the tongue protruded, and there were other clear indications of the child having been strangled. The hydrostatic test applied to the lungs proved that respiration had been performed.

When the mark on the neck is deep, broad, much ecchymosed, and there is extravasation of blood beneath, with injury to the muscles or trachea, and ruffling or laceration of the skin, it is impossible to attribute these appearances to accidental compression by the navel-string. The lividity produced by it in the cases hitherto observed has been only slight and partial, and unaccompanied by laceration of the skin, or injury to deep-seated parts. On the other hand, in homicidal strangulation, as much more violence is commonly used than is necessary for destroying life, we may expect to find great ecchymosis and extensive injury to the surrounding soft parts. On some occasions all difficulty is removed by the discovery of a rope, tape, or ligature, tied tightly round the neck; or, if this be not found, the proofs of some ligature having been used will be discovered in the indentations or irregularly ecchy-

mosed spots left on the skin—the depressed portions of the skin being generally white, and the raised edges livid or œdematous.

It has been doubted whether a child can be born with the navel-string so tightly round the neck as to produce great depression of the skin and ecchymosis, *i. e.* to simulate homicidal strangulation, and at the same time perform the act of respiration fully and completely. It is important, therefore, when this hypothesis is raised in order to account for a suspicious mark on the neck, to examine closely the state of the lungs. Unless the cord be designedly put round the neck of the child *after* the head has protruded, the effect of the expulsive efforts of the uterus, when a coil has become *accidentally* twisted round the neck, would be to tighten the cord, compress the vessels, and kill the child by arresting the maternal circulation, at the same time that this pressure would effectually prevent the act of breathing. Hence the lungs usually present the appearances met with in still-born children generally; but the case which occurred to Dr. Williamson (p. 655) shows that this state of things may sometimes occur, and that a child may breathe, and die strangled by the umbilical cord before its body is entirely born. Medical witnesses, however, should not be too ready to accept such a suggestion: a careful examination of the neck will show whether a ligature has or has not been wilfully applied after birth. In *Reg. v. Robinson* (Lewes Summer Ass., 1853), there was around the neck, the mark of a ligature which had been *tied very tightly*. The child had fully breathed, and according to the medical evidence it had died from strangulation, owing to an accidental twisting of the cord during delivery. In examining a suspicious mark on the neck of a new-born infant, it is proper to notice whether it does not, by its form or course, present some peculiar indentations which may render it certain that a ligature has been wilfully employed after birth. When it is found that a child has fully breathed, the presence of a deeply ecchymosed or an œdematous mark on the neck with injury to the skin and muscles is, *cæteris paribus*, presumptive of homicidal strangulation. Death from accidental constriction of the cord during delivery should, as a general rule, leave the lungs in their foetal condition.

Marks on the neck of a child may be accidentally produced by the navel-string without necessarily destroying the child's life. Two cases of this kind are reported by Professor Busch ("Brit. and For. Med. Rev.," vol. 10, p. 579); and a child may be destroyed without ecchymosis being a necessary consequence of the constriction produced by it. There is much less risk of strangulation from twisting of the cord during birth than is commonly believed. Out of 190 cases Dr. Churchill found the cord round the neck in fifty-two children, and the shortest cord so disposed was eighteen inches long; Dr. Négrier found it round the neck in twenty cases out of 160 natural labors. ("Ann. d'Hyg.," 1841, vol. 1, p. 137.)

The *appearances* met with in the body in death from strangulation have been elsewhere fully considered (p. 456, *ante*). The facts of a case communicated to me in March, 1865, by Mr. Cann, of Dawlish, will, however, serve to show the appearances which may present themselves in a new-born child. A maid-servant in a family was secretly delivered of a child. When the body was found, it was observed to be full-grown,

and there was a piece of tape which had been tied tightly in a bow, twice round the neck. The tongue protruded between the lips; two deep furrows were found round the neck after the removal of the tape; there was great oedema with swelling of the skin between and above them, and the right hand was clenched. The lungs were of a light-red color: they filled the chest, were highly crepitant, and floated readily on water, even when divided into sixteen pieces, and these had been submitted to strong pressure. They weighed, however, only 626 grains. The heart was healthy: the right side contained some coagula of blood—the left side was empty; the foramen ovale was open. The scalp was much congested, the congestion almost amounting to small effusions of blood: the pia mater was also congested. The inferences drawn from these facts were, that the child had been born alive, and that it had died from strangulation. The lungs were as light as they usually are in the fetal state, showing that, although they had received air, the pulmonary circulation had not been perfectly established. Juries take a very lenient view of these cases of death by strangulation. In *Reg. v. Cresswell* (Gloucester Spring Ass., 1878), the child was found dead with a cord tied tightly round its throat. It was clear that it had been born alive, and had died from strangulation. It was suggested for the defence that the cord was tied round the throat to conceal the birth, and not with intent to murder. The woman was found guilty of manslaughter!

Accidental marks resembling those of strangulation.—In the fore part of the neck of a child a mark or depression is sometimes accidentally produced by forcibly bending the head forwards on the chest, especially when this has been done repeatedly and recently after death, while the body is warm. It may occur, also, as an accident during labor. Such a mark must not be mistaken for the effect of homicidal violence. It has been a question whether, independently of the constriction produced by the umbilical cord, the neck of the uterus might not cause, during its contractions, an ecchymosed mark on the neck. I am not aware that there is any case reported which bears out this view; and it seems highly improbable that any such result should follow.

The discoloration may be in detached spots or patches—situated in the fore part of the neck, and evidently not arising from the employment of any ligature. These marks may depend on the forcible application of the fingers to the fore part of the neck of the child, and the indentations have been known to correspond—a fact which has at once led to a suspicion of the cause of pressure and the mode of death. At the same time, it should be borne in mind that a superficial mottling of the skin occurs after death in new-born infants, in parts where moderate pressure only may have been accidentally produced. This would not be attended with ecchymosis, and its true nature would be at once determined by comparing the discolored spots with the surrounding skin. It may be alleged, in defence, that such marks might have been accidentally produced—1. By the forcible pressure produced by the child's head during labor. 2. They will be more commonly referred to violent attempts made by a woman at self-delivery, during a paroxysm of pain. This explanation is admissible, so long as it is confined to injuries which, by any reasonable construction, might be caused during labor; but supposing

the marks to have been certainly produced after the complete birth of the body, it will not of course apply.

Among marks simulating violence, which are sometimes found on the necks of new-born children, Mr. Harvey has pointed out one of a singular kind. In February, 1846, he was present at a delivery in which a child was expelled rather suddenly; and after making two or three convulsive gasps, it died. Whilst endeavoring to restore animation, he observed a bright-red mark extending completely across the upper and fore part of the neck, from one angle of the lower jaw to the other, as though it had been produced by strangulation with a cord, except that the mark was not continued round to the back of the neck. It was of a vivid red color, and not like a bruise or ecchymosis, but it had very much the appearance of a recent excoriation. It was most clearly defined in front, where it was about a quarter of an inch in breadth, and it became diffused at the sides. The face was not swollen, and there was no fulness of the veins. ("Med. Gaz.," vol. 39, p. 379.) A distinction in this instance might have been based upon the color of the mark, the uninjured state of the cuticle, and the absence of congestion of the face and venous system. Nevertheless, the fact is of some importance, and should be borne in mind during the examination of the body of a new-born child alleged to have been strangled. Another case, which was the subject of a coroner's inquest, was published by Mr. Rose in the same journal (vol. 37, p. 530), in which red marks on each side of the nose of a new-born child were mistaken for the effects of violence applied to the nostrils during a supposed attempt at suffocation. Mr. Rose examined them closely, and considered that they were *nævi* (mother's marks), and had nothing to do with the death of the infant.

A medical witness may be asked on these occasions, whether he will undertake to swear that the ligature or the fingers had been applied to the neck of a child before or after its death, or before or after it had breathed. It is proper to observe that, so far as external marks of strangulation are concerned, there is no difference in the appearances, whether the constriction is made during life, or immediately after death while the body is warm. Casper's experiments render it highly probable, that when a constricting force is applied to the neck of a dead child, at any time *within an hour* after death, the marks cannot with certainty be distinguished by any appearance from those made on a living body. ("Wochenschrift," Jan. 1837.) With regard to the second point, it may be stated, that whether the child has breathed or not, provided it be *living* and the blood circulating, marks of violence on the neck will present precisely the same characters. In the absence of any visible discoloration of the skin, it may be a question whether this should be taken as evidence of the means of constriction not having been applied during life. What we are entitled to say from observed facts is, that ecchymosis from the ligature is not a necessary consequence of constriction, either in a living or a recently dead child: although we might expect that there would be few cases of deliberate child-murder in which, when strangulation was resorted to, there would not be some ecchymosed mark or discoloration, chiefly from the presumption that great and unnecessary force is suddenly applied. Besides, it is not improbable that a slighter degree of force

would cause ecchymosis on the skin of a new-born infant, than would be required to produce such an appearance on that of an adult.

Another question has been put—namely, whether a medical witness will undertake to say that the constricting force had not been applied to the neck of the child until after its body had been entirely born. This, of course, must be a pure matter of speculation. The appearance caused by a ligature applied to the neck of a *living* child, would not be different whether the child was partially or entirely born. If the child had actually breathed, the appearances in the body would be the same, and there are no medical facts by which it could be determined whether the act of strangulation proved fatal during birth or afterwards. A medical witness has also had this question put to him—Whether the strangulation occurred before or after the navel-string was severed. It would appear that the severance of the cord has been sometimes regarded as a legal test of an independent circulation being established in the child; but this is obviously an error, depending on a want of proper information respecting the phenomena which accompany birth. Respiration, and therefore an independent circulation, may take place *before* the cord is divided; and its severance, which is never likely to occur until after birth, cannot consequently be considered as a boundary between a child which is really born alive, and one which is born dead. A premature severance might possibly endanger the life of a child, instead of giving it an independent existence. A healthy and vigorous child may continue to live and breathe independently of the mother, before the division of the cord, and the time at which the severance is made depends on mere accident. Hence the marks of strangulation on the neck of a living and breathing child, must be the same whether the cord has been divided or not. The entire birth of the body is, however, now considered to be legally complete although the navel-string has been divided.

8. *Poisoning.*—This is placed among the possible means of perpetrating child-murder, but we rarely hear of *new-born* children being thus destroyed. Children destroyed within a week of birth generally die from some acts of violence like these already described, the object of the perpetrators of the crime being to ensure a rapid and certain death. Professor Hofmann of Vienna describes a case in which a girl destroyed her child by *nux vomica* on the second day after birth. She mixed the powder with camomile tea, and gave it to the child. It had convulsions, and died in three hours. Cadaveric rigidity was strongly developed in the body of the child when found on the third day. No particular appearances were met with except those of asphyxia in the chest. No trace of strychnia could be detected in the stomach or liver. The earliest age at which I have known a trial to take place for the murder of a child by poison was two months. (*Rex v. South*, Norf. Aut. Circ., 1834.) A quantity of arsenic was given to an infant, and it died in three hours and a quarter after the administration of the poison. At this age the case can scarcely be called one of infanticide in a medico-legal signification, because all that it would be necessary to prove would be the cause of death; the question of life or live birth would not require to be entered into. If in a case of child-murder, death from poison should be suspected, it must be

sought for in the usual way. Some cases have occurred, in which children have been wilfully destroyed a week or two after birth, by the administration of opium or excessive doses of purgative medicine. Oil of vitriol has been also used to destroy life.

In cases in which infants are destroyed by poison, there is generally great difficulty in tracing the act of administration to the guilty person. The fluid food given to them renders the admixture of poison easy, and as many persons may have access to this food, it is often impossible to fix upon the criminal. In one instance which came to my knowledge, an illegitimate child had been placed out to nurse by its mother, a woman in a good social position. It was noticed that after each visit paid by the mother the child was sick, and after repeated attacks of illness, the child died. On inspection arsenic was found in the body, and this was beyond doubt the cause of death. There was no suspicion against the nurse; but a strong suspicion fell on the mother, from the circumstances above mentioned. There was evidence, however, that the child was not at any time fed by the mother when she visited it, and that the mother had no access to the child's food. No poison could be traced to her possession, and she was not seen by the nurse, who was present, to give anything to the infant. The only fact that transpired was that, at each visit, she took it in her arms and was observed to rub its gums with her fingers, and soon after her visits, sickness followed. There was reason to believe that she had concealed small quantities of arsenic under her finger-nails, and that she had administered the poison while rubbing the gums of the child!

Conclusions.—The following conclusions may be drawn from the preceding remarks:—

1. That congestion of the face and head in a new-born child, is not a proof of death from strangulation.

2. That strangulation can take place only in children which have breathed.

3. That a child may be strangled during birth by the accidental twisting of the navel-string round its neck.

4. That the navel-string may produce a livid or ecchymosed depression on the neck, like any other ligature.

5. That marks on the neck produced by accidental causes, may resemble those which arise from strangulation.

6. That the effect of constriction on the neck, either by the navel-string or any other ligature, is the same, if the child be *living*, whether it has or has not breathed.

7. That the effect is the same whether the child has been *partially* or *entirely* born.

8. That the effect of a ligature on the neck of a *living* child is the same whether the navel-string has or has not been severed.

9. That a new-born child may die from strangulation, without this fact being necessarily indicated by ecchymosis on the neck. This depends on the nature of the ligature, and the amount of force used.

Examination of women. Medical responsibility.—In general it is the mother of the child who is charged with the murder; and in this case it may be necessary, in order to connect her with the child, to determine

whether she has or has not been *recently delivered*. Medical evidence may show that the date of delivery does or does not correspond with the date of the birth and death of the child. The usual appearances in cases of recent delivery both in the living and dead body, have been elsewhere fully described. (See DELIVERY, *ante*, pp. 554-561.) These appearances necessarily vary according to the time at which the examination is made. M. Toulmouche has reported in detail several cases showing the post-mortem appearances met with at different dates. ("Ann. d'Hyg.," 1864, 2, 349.)

If the reputed mother of the child is *dead*, a coroner or magistrate may issue an order for a post-mortem examination of the body, and the case will present no difficulty; if *living*, a serious question may arise as to medical responsibility. In general, a woman consents to be examined, but it may happen that she will refuse to submit to a physical examination. An innocent woman is just as likely to refuse permission as one who is guilty; but, if circumstances point to one out of several women in a household, the refusal to permit an examination would of course be interpreted against her. It has happened on more than one occasion that medical men have assumed to themselves the right of enforcing an examination of suspected women, and by threats or otherwise, they have compelled them to undergo this. Such a course of conduct is in the highest degree indecent and improper; but when a woman willingly consents to be examined, a medical man is justified in making an examination, and giving evidence thereon. It would, however, be only fair in such a case to give her the warning which every magistrate and coroner is bound to give to any woman charged with murder, before requiring an answer to a question which may be used in evidence against her at the subsequent trial.

The case is widely different, however, when a medical man takes this authority upon himself, and compels a suspected woman unwillingly, or under duress, to submit to a physical examination. By taking this illegal course, he is forcibly compelling a woman accused of murder, to produce positive proof of her guilt—such a course is entirely opposed to the spirit and practice of English jurisprudence. The mischievous results of such officiousness on the part of a medical man are well illustrated by the following cases. The first of them is noticed in the "Lancet," May 29, 1869. A surgeon and an inspector of police, at Hitchin, insisted upon examining two women, a mother and daughter, in order to determine whether either of them had been lately delivered of a child. This was against their consent, and in the absence of the husband and father. He brought an action against them and recovered damages. ("Lancet," Sept. 2, 1871, p. 333.) The other case was that of *Weir and Wife v. Hodyson*. (Liverpool Winter Ass., 1861.) The dead body of a child had been found near the house of the plaintiff. The defendant, a surgeon, went with an inspector of police to see Mrs. Weir; and, having informed her that she was suspected of having had a child, told her that he had come to examine her by the authority of the law, and that she must submit. She refused at first, and proposed to send for a medical man whom she knew. In the end the defendant examined her, and found that there was no ground for the charge. The

jury returned a verdict of 200*l.* damages for the assault! . . . The police can give no legal power to a medical man to make such an examination in a suspected case, and the ultimate consent of the woman, if extorted by threats or intimidation, will be no answer to a charge of indecent assault. One of the latest cases (*Warne v. Serjeant*) was tried at the Manchester Winter Ass., 1878. It was here doubtful whether the woman had given her consent to an examination, and the jury found a verdict for the defendant. The judge observed that even if the surgeon had been honestly misled by the woman's conduct, it would still be an assault.

In all cases, whether the charge against a woman be one of concealment of birth, abortion, or child-murder, a medical man must act upon his own discretion. An examination of her person, with a view to obtain evidence against herself, is unlawful except with her free consent.

A coroner issuing an order for the compulsory examination of a woman under these circumstances, would be acting *ultra vires*, and any medical man obeying it would incur a serious responsibility. In August, 1871, a case occurred near Leominster, which has placed this question in cases of alleged infanticide in a painful light. A young lady, the sister of a clergyman, committed suicide rather than submit to a physical examination by two medical men, under the order of a coroner. The coroner held an inquest on the body of a child in a case of alleged child murder. A suspicion arose that this young lady had been recently delivered. Two medical gentlemen, provided with a written order from the coroner, went to the rectory where the lady was residing, and requested an interview with her for the purpose of ascertaining whether she had recently had a child. She refused to see them, and subsequently destroyed herself. All the particulars of this tragedy were not made known, but the attempt to examine this young woman for the purpose of obtaining evidence against her on a charge of child-murder, appears to have had such an effect on her mind as to lead to suicide. The fragmentary particulars of this sad case will be found in the "*Lancet*" for 1871, vol. 2, pp. 333, 471, and 477. The 6 and 7 Will. IV., c. 89, under which an order was issued by the coroner on this occasion, empowers a medical man to examine a *dead* body, and give evidence touching the cause of death; but it says nothing about the examination of *living* women. Such an order would be obviously illegal, and a medical man acting under it would render himself liable to an action for an indecent assault.

It can only be by the free consent of the person inculpated, that a personal examination for evidence can be made. The *Tichborne* case has furnished a good illustration of the care taken by our judges that an accused person shall not unknowingly furnish evidence against himself. It was alleged on this occasion that if the "claimant" had been bled in the temporal artery, a scar would remain; and a proposition was made that he should be then examined by two medical witnesses who had been called for the prosecution. The Lord Chief Justice Cockburn ruled that such an examination could not be made except by the consent of the accused. This was given, and the examination accordingly took place in court. A similar rule has been long acted on in the Scotch courts. Thus in a divorce case tried in 1860 (*Edinburgh Sessions cases*, 1860), the

court refused to receive certain evidence which was tendered regarding the condition of a woman, on the ground that they could not compel her to submit to another examination, and the evidence tendered would therefore have been entirely *ex parte*. In July, 1873, in a suit of nullity in the English Divorce Court, Sir J. Hannen was obliged to decide the case upon the evidence of the husband only. The wife refused to submit to an examination, and there was no legal power to compel her to undergo this, against her will. (*Hewitt v. Pery*, falsely called *Hewitt*, July, 1873.) These cases suffice to show the course which a medical witness should pursue on all occasions in which a person does not voluntarily consent to a personal examination.

It is creditable to the authorities of the borough of Leeds that they have issued a paper of instructions to their constabulary force, with regard to the duties and legal liabilities of police surgeons, when women are charged with child-murder, criminal abortion, or concealment of birth. ("Town Clerk's Report," April, 1878.)

BIRTH. INHERITANCE.

CHAPTER LV.

LIVE BIRTH IN CIVIL CASES.—DATE OF BIRTH.—SIGNS OF LIVE BIRTH INDEPENDENTLY OF RESPIRATION OR CRYING.—VAGITUS UTERINUS.—TENANCY BY COURTESY.—LEGAL BIRTH.—POST-MORTEM BIRTHS.—MINORITY AND MAJORITY.—PLURAL AND MONSTROUS BIRTHS.

Date of birth.—Medical evidence has occasionally been demanded in courts of law respecting the actual date of birth in those cases in which a period of a few days, hours, or even minutes, was required to prove the attainment of majority,—and therefore a legal responsibility for the performance of civil contracts into which the parties had entered, either knowingly or ignorantly, when minors. Some such cases have been decided by the evidence of the accoucheur himself,—others, when the accoucheur was dead, by the production of his case-books; and it is worthy of notice that the strictness and punctuality of some medical practitioners in making written memoranda of cases attended by them, have in more than one instance led to a satisfactory settlement of such suits, and the avoidance of costly litigation. The proof of the exact date of birth is also of considerable importance in certain cases of contested legitimacy.

Medico-legal questions connected with this subject arise in contested suits relative to succession or the inheritance of property. A child that is born alive, or has come *entirely* into the world in a *living* state, may

by the English law inherit and transmit property to its heirs, even although its death has immediately, and perhaps from morbid causes necessarily, followed its birth. Should the child be born dead, whether it died in the womb or during the act of birth, it does not acquire any civil rights; for it is not regarded as a life in being, unless it manifests some sign of life *after* it is entirely born and separated from the mother. Some have considered that *partial birth*, provided a child is living, should suffice to confer the same rights on the offspring as the proof of entire birth; but great difficulty might arise in civil cases, if the bare extrusion of a *part* of the body sufficed for all legal purposes of *entire* birth. It might become a casuistical question, as to how much of a body should be in the world in order to constitute legal birth; for there is no reason why, in a medical sense, the extrusion of the head and shoulders should constitute birth any more than the extrusion of a hand or a foot. If it be said that the act of breathing should be combined with a partial extrusion of the body, this would be unjust; because a child is alive—its heart is evidently pulsating, and its blood circulating, as freely before the act of breathing as afterwards. Besides, it is admitted that children may be born alive, and live for some time without respiring; and this want of respiration is no objection to these children being considered living in law. In a case referred to hereafter, a child was pronounced to have been legally born alive, although it had certainly not breathed; and that a child may manifest life for a certain time without leaving in its body any evidence of respiration is clear from numerous reported cases (p. 600, *ante*). If, then, proof of respiration be not demanded in cases of entire, it could scarcely be required in cases of partial birth. In the event of partial being treated as synonymous with entire birth, there would be no end to litigation; and medical opinions would vary in every case. It is doubtful whether, under such circumstances, the law could be administered with any degree of certainty or impartiality. Admitting, then, that a child must be *entirely* born in order that it should acquire civil rights, it will next be necessary to examine the proofs required to show that it has been *born alive* in a legal sense. The question here is different from that of live birth in reference to child-murder. We may presume that a practitioner is present at a delivery in which a child is born in a doubtful state, or where its death speedily follows its birth. The civil rights of the child and its heirs, will depend upon the careful observation made by a practitioner, of the circumstances attending the delivery. It is proper that he should note the time when the birth is completed, by the body of the child being entirely out of the body of the mother. Children born at or about midnight are liable to have the date of birth wrongly registered; and the legal difference of twenty-four hours, which a few seconds or minutes may make, may hereafter affect their own rights, if they survive, or those of others, if they die.

Signs of live birth independently of respiration, or crying.—The visible respiration of a child after its birth, or as it may be manifested by its *crying*, is an undoubted sign of its having been born alive; but as it has just been stated, a child may acquire its civil rights, although it may be neither seen to breathe, nor heard to cry. The pulsation of a

child's heart, or even the spasmodic twitching of any of the muscles of the body, has been regarded as a sufficient proof of live birth. The latter sign has been judicially so pronounced—*à fortiori*, therefore, the motion of a limb will be considered sufficient legal evidence, in an English court of law, of life after birth. It is to be observed that the length of time during which these signs of life continue after a child is born is wholly immaterial: all that is required to be established is, that they were positively manifested. A child which survives entire birth for a single instant acquires the same civil rights as if it had continued to live for a month or longer. These facts will be better understood from the following case (*Fish v. Palmer*), which is reported to have been tried in the Court of Exchequer in 1806. ("Beck's Med. Jur.," vol. 1, p. 354.) The wife of the plaintiff *Fish* was possessed of landed estate in her own right. She died in 1796, after having given birth to a child which was supposed at the time to have been born dead. In consequence of the plaintiff's not having had a living child (as it was assumed) during the marriage, the estate of the wife was claimed and taken by the defendant *Palmer*, her heir-at-law—the husband being obliged to surrender it under the circumstances. From information derived many years after the death of his wife, from some women who were present at the delivery, the plaintiff was led to believe that the child had not been born dead, and that the estate had therefore been surrendered to the plaintiff under a mistake. An action was brought to decide this question in 1806, ten years after the death of the wife, and it lay with the plaintiff to prove his allegation that the child had been born *living*. Dr. Lyon, the accoucheur, had died some time before the trial; but it was proved that he had declared the child to have been living an hour before it was born, that he had directed a warm bath to be prepared, and when the child was born, gave it to the nurse to place in the bath.

The child neither cried nor moved after its birth, nor did it manifest any sign of active existence; but the two women who placed the child in the bath swore that when it was immersed there appeared twice a *twitching or tremulous motion of the lips*. They informed the accoucheur of this, and he directed them to blow into its throat, but it did not show any further signs of life. The main question in the trial was whether this tremulous motion of the lips was a sufficient proof of the child having been born alive. The obstetric experts who were summoned to give evidence on this occasion differed in opinion. Drs. Babington and Hughton stated that had the child been born *dead*, or had the vital principle been extinct, there could have been no muscular movement in any part of its body; therefore the child had, in their opinion, been born alive, and had manifested some evidence of life after its birth. Dr. Denman, who was called for the defendant, dissented from this view. He contended that from the evidence the child had not been born alive, and in explanation of this drew a distinction between uterine and extra-uterine life. He attributed the tremulous movements of the lips after birth to the remains of uterine life. The jury, however, under the direction of the court, did not adopt this view of the case. They pronounced by their verdict that the child had been born living, and the plaintiff thus recovered an estate of which he had been for ten years deprived.

From the result of this case it would appear that the English law does not recognize any distinction between uterine and extra-uterine life, as drawn by Dr. Denman. The question is simply life or death—living or dead? Dr. Denman did not assert that the child was born dead. On the contrary, he assigned the movements observed by the witnesses to the continuance of life—but of *uterine* life. The act of breathing is commonly set down as the boundary; but a child is not necessarily dead until it breathes, as the recovery of numerous children born with uterine life clearly proves. The fallacy of trusting to breathing as a criterion in the living or dead body is fully shown in the chapter on INFANTICIDE. Breathing is justly regarded by the English law as only one sign of life; and proof of the possession of active and vigorous life is not required. It cannot be admitted, physiologically, that any tremulous motion of the muscles can ever take place spontaneously in the body of a child really dead, and the spasmodic movement of the lip differs only in degree from the motion of a leg or arm, or of a rib by the intercostal muscles. If a certain quantity or degree of life were required to be proved, instead of the bare fact of its actual presence or entire absence, the most subtle medical distinctions would be continually drawn. Non-professional persons might be easily deceived as to the act of breathing in these feeble subjects, and an examination of the dead body would not suffice to remove the doubt, since new-born infants may live for hours without any air being found in the lungs; but a person is not so likely to be deceived about the movements of an arm, a leg, or a lip.

It has been objected to this view of the case that the movements described may be the mere remains of muscular irritability, and not a sign of actual life or the vital force; but it seems to me that this is practically an admission of the presence of life, or vital force under another name. Muscular irritability and spontaneous contractions are not manifested in bodies really dead, and their spontaneous occurrence proves that some vital power must still remain in the body of a child.

Some medical jurists have contended that there should be, in all cases, evidence not only of the breathing, but of the crying of a child, in order to justify a medical opinion that it was born alive; but according to Blackstone ("Commentaries," vol. 2, ch. 8, p. 127), "*Crying*, indeed, is the strongest evidence, but it is not the *only* evidence;" and Coke says, "If it be born alive it is sufficient, though it be not heard to cry, for peradventure it may be born dumb;" he also describes "*motion*, stirring, and the like," as proofs of a child having been born alive. So far the decision of *Fish v. Palmer* is borne out by good legal authority; and we may consider that although the mere warmth of the body would not be evidence of live birth, yet the slightest trace of *vital* action, in its common and true physiological acceptation—such as crying, breathing, pulsation, or motion—observed after entire birth and separation from the mother, would be deemed, in English law, a sufficient proof of the child having come into the world alive.

A late eminent Scotch judge informed me that in Scotland, the husband's right of courtesy, or life-rent in his wife's estate, depends upon there having been a child of the marriage born alive; and for the proof of live birth it is required to be shown, not merely that it had breathed,

but that the child had cried after it was born. Dr. Beck remarks that the Scotch law is more precise than the English, in thus demanding proof of *crying*; but it should be added that it is more unjust. The case of *Dobie v. Richardson* (Court of Session, 1765) is sufficient to prove this. Dobie's wife brought forth a child about nine months after marriage which breathed, raised one eyelid, and expired in convulsions about half an hour after its birth, but *was not heard to cry*. The mother died in child bed, and the question was whether the *jus mariti* was not lost by the death of the wife within the year, without a child of the marriage which had been heard to cry. The decree made in the case was, that as the wife did not live a year and a day after her marriage, and as it was not proved that the child or foetus, of which she was delivered, was heard to *cry*, the husband was not entitled to any part of his deceased wife's effects (Beck's Med. Jur., 1, 358). The learned judges in this case did not stultify themselves by affirming that the child in question was born *dead*. This is a physiological and not a legal point. A child which died in convulsions half an hour after its birth could not be described as having been dead. The law of any country may assume its own standard of life at birth. The Scotch law thus assumes "audible crying," but it cannot alter the physiological fact that a child may be born living without crying. It is not merely a living but a "crying" child which conveys the right of courtesy to the husband across the border. This will be further seen from the decision in the case of *Blackie* (Court of Session, 1833).

There is some reason to believe that, in any future case, this will not be taken as a precedent. The attainment of greater knowledge on the nature and the proofs of life from the results of medical experience and observation, and the fact that these physiological questions have become more generally known and better understood, will probably lead to a different decision. That there should not be a power of proving life (when the death of a child takes place speedily after birth) except by direct evidence that the child had cried, is in truth a view of the matter wholly indefensible. From what will be hereafter stated (*Flagitus uterinus*, infra) it will be seen that the crying of the child is not necessarily a sign of live birth, for it may cry during the act of birth, and die before its body is born; while the fact that it breathes and moves after birth, although from accidental circumstances it may not cry, is unexceptionable evidence of its having been born alive.

The case of *Brock v. Kelly* involved a claim by a widow to the estate of her husband, on the ground that a child born twenty years before had been born living, although it was at first supposed to have been stillborn. The case came before Vice-Chancellor Stuart, in April, 1861, and his decision confirmed the views here expressed. Dr. Freeman noticed at the birth of this child, and after separation from the mother, that there was a slight pulsation in the cord, showing a feeble but independent circulation. There was no other indication of breathing than an arched state of the chest. He had, it appears, made an entry in his diary of the birth being that of a *live* child, and believing it to be alive, he caused it to be placed in warm water to sustain its vitality; he felt sure of its being alive, for the reason above assigned. This statement was confirmed

by the nurse, who had been heard to say that the child was born alive, but died the same day. This may be regarded as strong evidence that the child was really born with life, although in a passive state of excitation. At the time when these observations were made, namely, twenty years before, the legal question of live birth was not raised, and there could have been no conceivable motive for misstating the facts, or inventing a state of things to suit a legal claim.

Dr. Tyler Smith supported the opinion of Dr. Freeman in an affidavit, considering that the fact that pulsation was observed in the umbilical cord after delivery was a physiological proof that the child in question was not born dead. On the other side, Drs. Lee and Ramsbotham gave their opinion that there was no proof in this case of breathing having taken place after birth, and that nothing less than breathing could establish the fact of live birth! The child, therefore, in their judgment, was not born alive. In their judgments, a child must breathe before it can be said to possess independent life. The Vice-Chancellor decided the proof of breathing was not necessary, and held that there was sufficient legal evidence of life after birth in the pulsation observed by the accoucheur. This decision is in accordance with law and common sense. Pulsations indicate an action of the heart, as much as motion of the chest indicates an action of the intercostal muscle.

There is a difficulty in relying upon the suggested proof derivable from the presence of air in the lungs. It is well known, and cases are described under the section of INFANTICIDE, that a child may breathe and die before its body is born. Therefore, unless there are eye-witnesses to testify to the act of visible breathing, the test is not only valueless, but fallacious. It would mislead a court of law. On the other hand, children are born and live for many hours in a state of passive existence, and after death no air is found in the lungs. These are the cases which would be truly pronounced stillborn by those who were not present at the birth, although the accoucheur and nurse may have distinctly seen movements of the arms, legs, or lips, or even a convulsed state of the body! Many cases of this kind are described in the section on INFANTICIDE; for such cases of life without respiration have been thought to form a serious obstacle to any inference from experiments on the lungs.

The following case, in which all the facts were accurately observed in reference to the manifestations of signs of life after birth, and the duration of life in a new-born child, clearly proves that the English courts are correct in relying upon proofs of life, irrespective of breathing or crying. It shows, too, that the decision of Vice-Chancellor Stuart in the case of *Brock v. Kelly* was based on sound physiological reasons, and that any other decision would have been unjust. This case occurred to Dr. Seale, U. S. ("Amer. Journ. Med. Sci.," July, 1870, p. 278.) He induced labor in a woman by ergot of rye, at about the seventh month of gestation. A large child was born after some difficulty, but it did not make the slightest effort to breathe. There was distinct *pulsation in the cord*. Was this child living or dead? As it had not breathed, according to some accoucheurs, it would be regarded as dead. The pulsation of the cord would be treated as of no importance, *i. e.*, as giving no indication of life after birth. But this child was really born living, a fact

proved by what followed. Flagellation and alternate sprinkling with hot and cold water produced a violent spasmodic contraction of the diaphragm, which caused the entire infra-mammary region to be very much depressed. There was no doubt that this was a case of atelectasis pulmonum, or inexpansibility of the lungs, a state which continued for *five minutes* after the birth of the child. The cord was now severed, and about half an ounce of blood was allowed to flow slowly from the foetal end. The tongue, which had fallen back, was drawn forward. A sudden spurt of a drachm of blood flowed when the constriction was relieved, and the child began to breathe very feebly, and so continued to breathe at long intervals. The heart beat very feebly. The pupils were widely dilated, they did not respond to the influence of a bright light, and the child was suffering from all the symptoms of compression of the brain. This condition lasted one hour, when the child ceased breathing.

According to the evidence of Drs. Lee and Ramsbotham in the case of *Block v. Kelly* (p. 668 *ante*) this child was born dead, and would have been so pronounced for the first five minutes after birth, the pulsation of the cord and the spasmodic movement of the diaphragm being regarded by them only as indications of uterine life. Yet it is clear that this child was born living—that it lived before the act of breathing, which after all was performed only in the most imperfect manner. To have pronounced it dead within the first five minutes of its birth, and living for an hour afterwards, would have been inconsistent; yet if the slight indications pointed out were not signs of continued life these conclusions would necessarily be drawn, involving a *reductio ad absurdum*. The child would have had no power of inheriting or transmitting property for the first five minutes after its birth because it was dead, and would have acquired this power for the last fifty minutes because it was living! According to the French law a child so living for five minutes, or an hour, after birth would be pronounced non-viable and incapable of acquiring or transmitting property.

A healthy full-grown child recently born may make an attempt at inspiration, but the closure of the larynx from convulsions, or some irritant such as the vaginal discharges, meconium, etc., may impede the entry of air into the lungs. The chest in this case is arched, the head thrown back, and there is a convulsive rigidity of the muscular system; the tongue is firmly retracted, especially at its base. Unless the finger of the accoucheur is passed quickly down the base of the tongue, and the epiglottis raised by pressing it forwards, the child would never inspire, although it might have a perfect capacity to breathe. Dr. Braxton Hicks met with a case of this kind; air entered the lungs immediately after the above operation, and the child breathed and lived. According to the theories propounded in reference to the cases of *Fish v. Palmer* and *Brock v. Kelly*, this child would have been pronounced dead or stillborn up to the time at which the accoucheur removed the impediment to its breathing. It has been observed that a respiratory action ensues upon any stoppage of the placental supply to the child, and, moreover, that this may occur in the uterus as well as in the vagina; and it has been remarked that foreign substances, which had been drawn in under these circumstances, may be found in the bronchial tubes. If this be so, then

the finding of the natural secretions in the bronchial tubes would not be an absolute proof of inspiration having been established ; it would merely show that there had been an action of the chest during birth similar to that of inspiration. Still this must be regarded as a living action, and therefore indicative of life in the child.

There is no doubt that the best test to apply to such cases for the determination of *physiological* life is *auscultation*. The beating of the heart, as determined by the ear or the stethoscope, applied even for five consecutive minutes, is an undoubted sign of life, in a physiological sense, whether the child breathes, cries, or moves. M. Bouchut noticed, on one occasion, that this kind of passive life continued in an infant for twenty-three hours after its birth. Feeble but distinct pulsations were heard at long intervals, but there was no motion of the ribs. Attempts at resuscitation were made, but the motions of the heart became more and more feeble, until they entirely ceased. An examination showed that the lungs had not received air. As we take the cessation of the heart's action to be the only certain evidence of death, so the existence of pulsation in the heart or arteries, when clearly perceived by the ear, stethoscope, or finger, is positive evidence of life in a physiological sense. Is this *legal* life ? Would the wilful destruction of such a child constitute murder ? Would this proof of pulsation without muscular motion, breathing, crying, or any other sign of active life, confer tenancy by courtesy, or transfer an estate by inheritance or survivorship ? M. Bouchut justly observes that apparent death succeeding to birth, and characterized by the presence of a beating of the heart and an absence of respiration, is only a diseased condition of the new-born child (see "Atelectasis," INFANTICIDE); and, whether it is cured of this or dies, it is living, although it has not breathed ; or, as a German jurist remarks, "*Scheintod ist Scheinleben*." By taking away its right of succession, the law punishes the child and its heirs for a malady with which it is born ("Gaz. des Hôp.," 1855, No. 124 ; and "Med. Times and Gaz.," August 19, 1856). They who contend that crying or breathing alone should be taken as a sign of life after birth, would of course pronounce such a child to have been born *dead*, even at the time that they might be listening to the pulsations of its heart ! (Casper, "Klinische Novellen," 1863, p. 564.) Such pulsations would probably be referred by them to the remains of uterine life of which the law takes no cognizance.

Vagitus uterinus.—Let us suppose that the evidence of a child having been born alive is stated to be that it was heard to cry—it may be a question for a medical witness, in cross-examination, whether this is to be taken as an absolute proof of live birth. The answer must be in the negative, because a child may cry before its body is entirely born ; or there may have been what is called *vagitus uterinus*—a uterine cry after the rupture of the membranes. (See INFANTICIDE.) It is quite certain that a child may breathe without crying, but it cannot cry without breathing ; yet neither the crying nor the breathing is an absolute proof that the child was actually born alive. As in all cases of this description there must be eye-witnesses, either professional or not ; the evidence will not rest solely upon a mere medical possibility of the occurrence of such a cry before birth ; and proof will be required of the crying of the

child *after* it was born. The determination of the momentary existence of children after birth is of importance in a legal point of view, in reference to the following subject.

Tenancy by courtesy.—This signifies, according to Blackstone ("Com.," vol. 2, p. 426), a tenant by the courts of England. If a married woman possessed of estate die, the estate passes from the husband to her heir-at-law, unless there has been a child born *living* of the marriage during the life of the wife, in which case the husband acquires a life-interest in the property. The only defence of this singular custom is, that it is of great antiquity. An unsuccessful attempt was made a few years since to substitute for it the reasonable provision, that the marriage should entitle the husband to the right, which he can now only acquire by the fulfilment of certain accidental conditions. Incurable sterility, a protracted labor, deformity in the pelvis of the wife, or the necessary performance of craniotomy on a healthy well-formed child, may, under this custom, lead to an aversion of the inheritance. The tenancy, in contested cases, is generally established or disproved by medical evidence; and the following are the conditions which the law requires in order that the right should exist:—

1. The child must be born *alive*. Cases have been already referred to in which the motion of a lip and the pulsation of the umbilical cord were held to be sufficient legal proofs of live birth. Some physiologists have objected to these as inadequate proofs of life in a medical sense; and if the question were one of pure physiology, and not of law, there might be some ground for the objection. In truth, however, the law does not require proof of *active* life in a child, but merely some evidence, however slight, that it has been born *living*; and the amount of proof to satisfy the purposes of justice must of course rest, not with physiologists, but with the expounders of the law.

The *crying* of a child, properly attested by disinterested witnesses, has been held in cases of disputed tenancy to be sufficient evidence of live birth; this is, in fact, one of the tests given by Lord Coke. At page 602, *ante*, some cases are related in which new-born children survived birth several hours, but manifested no signs of active life either by crying or in any other mode, and after death there was no air in the lungs. As in cases of infanticide, if the evidence of live birth rests entirely on an examination after death, the absence of air from the lungs will not necessarily show that a child has come into the world dead, nor will the presence of air in these organs prove that it has been born alive, because it may have breathed and died before birth. The child must be heard to cry, or be seen to breathe or move after birth. The fact that the lungs are not distended with air, and that they immediately sink in water, either when entire or when divided into small pieces, is no proof that a child has not breathed and cried during birth and afterwards. It does not require full inflation of the lungs for these conditions to exist. Dr. Barnes states that in experimenting on the lungs of children which had cried during birth, he has found that they sank in water. ("Brit. Med. Jour.," April, 1874.)

In a case noted by Mr. Willing, a woman was suddenly delivered at five and a half months. The child cried loudly when born. It survived

forty-four hours. The eyelids were perfectly closed. It weighed one pound and a quarter, and it measured from head to foot eleven inches. ("Obstet. Trans.," 1875, vol. 16, p. 86.) At p. 227. of the same volume, there is another case of a child born at the sixth month, which cried loudly several times, and lived twenty-one hours. It weighed one pound six ounces, and measured twelve inches in length. In a third case of a six months' child, which occurred to Dr. Vernon, p. 611, *ante*, it was strong enough to cry; and yet, probably, had its history been unknown, a medical witness would have been prepared to state, from an examination of the lungs, which contained no air and sunk in water, that it must have been born dead, and certainly could not have had the power of uttering a cry! A child born at the fifth month has been known to cry; but the state of its lungs is not recorded. In the case of *Gardner v. Llewellyn* (1856), a medical witness who appeared for the plaintiff stated as his belief that a child born at the fifth month could *not respire*, and if it could not breathe (so as to fill the lungs) it could not cry! This may have been consistent with his experience, but it is not consistent with facts observed by others. One of the greatest difficulties that lawyers have to contend with in getting at medical truth is this strong disposition on the part of witnesses to act upon a foregone conclusion, and to "fix" all natural events by an exclusive reference to their individual experience.

2. The child must be *born* while the *mother* is *living*. From this it appears that if a living child were removed from the outlet, or extracted from the uterus by the Cæsarean operation after the death of the mother, the husband would not become entitled to enjoy his wife's estate; although the child might survive its removal or extraction, and succeed to the estate on attaining its majority! How such a case would be decided in the present day it is difficult to determine; but one instance is quoted by most medico-legal writers from Lord Coke, in which, about three centuries since, the decision went against the husband in consequence of the child having been removed from the uterus by the Cæsarean section *after* the death of the wife. (For a singular case involving this question in France, see "Ann. d'Hyg.," 1838, vol. 1, p. 98.) In the case of *Llewellyn* (*supra*) the late Baron Alderson ruled that the husband could not take the estate unless the child was proved to have been born during the marriage, *i. e.*, during the life of the woman. One of the latest cases in which this question was raised on appeal is that of *Treherne v. Layton*, June, 1875. An estate had been left to the wife by her grandfather, after her death to her children, and in case she died leaving no issue, then to his next of kin. She had a child which just breathed and then died; and after her own death the estate was claimed by the next of kin, while the husband, the father of the child, claimed it as his child's heir-at-law. It was not disputed that the wife died "leaving no issue," but it was contended for the husband that the state was vested in his child by its momentary life, and all the judges held that it could not be divested by the child's death. The old custom of tenancy by courtesy was thus confirmed in spite of the words in the grandfather's will.

Cæsarean extraction.—The Cæsarean operation has rarely been performed in England except when a woman was actually dying or dead. A medical man wishing to perform it may find that the husband or representative of the deceased parturient woman will object to its performance, although the child may be living in the womb, and there may be a reasonable hope, by an immediate operation, of extracting it living. The late Dr. Lever informed me that on two occasions in 1858, the husbands thus refused to allow him to operate on the dead body of the wife. I apprehend that no medical man would proceed to operate by force, or against the will of the husband: at the same time, in refusing his permission, the husband is not guilty of any legal offence. The practice on the Continent has been to undertake it while the woman was living, and the result has shown that it may be performed successfully both with regard to mother and child. In cases in which a tenancy by courtesy would be likely to arise, it would be to the interest of the husband to allow the operation of extraction to be performed while the wife was living; but he would have no such interest in its performance after her death; and if the child has not attained a sufficient stage of maturity to survive, there can be no reasonable object in performing it. Important legal consequences may hereafter ensue from a more general adoption of this practice in England in respect to deformed women. Thus, supposing in any case a child were removed alive while the woman was living, both of them dying shortly afterwards.—Would the husband become a tenant by her courtesy? The law says the child must be *born*; and some lawyers would find ground for arguing whether extraction by the Cæsarean operation should be regarded as “legal birth.” “*Illud autem valdè controversum est inter jurisconsultos, an is qui editus est, exserto matris ventre, reputetur partus naturalis et legitimus et successionis capax.*” (Caranza.) According to Fonblanque, the question is settled in the affirmative—a child extracted is a child born. (“*Med. Jur.*,” vol. 1, p. 236.) Our ancient law authorities do not appear to have contemplated that the operation would ever be undertaken on a living female. The words of Lord Coke, which are considered to express the state of English law, are:—“If a woman seised of lands in fee taketh husband, and by him is bigge with childe, and in her travail dyeth, and the child is ripped out of her body alive, yet shall he not be tenant by the curtesie, because the child was not born during the marriage, *nor in the life of the wife*, but in the meantime her land descended.” According to Mr. Hobler, the Cæsarean operation does not divert the course of descent, or devest the husband of the life-estate, provided the child be born alive, and the mother was living when the child was born. (“*Obstetric Record*,” vol. 3, p. 66.) *Birth*, and extraction by the Cæsarean operation, are, therefore, treated by him as similar conditions.

There is no law to compel a man to perform this operation, and no law to prohibit it. Some years since the duty of a medical man on these occasions was made a subject of investigation by a committee of the French Academy of Medicine, and the conclusion at which they arrived, was that in the case of a pregnant woman recently deceased, a medical man might and ought to perform the Cæsarean operation, if there were

any probability of removing from her body a child in a viable state, *i. e.*, with a power to maintain an extra-uterine life. The date of viability, according to some authorities, is fixed at the 108th(?) day. Hence it is advised that no operation should be performed on a woman unless her pregnancy has reached this date. English practitioners would not be guided by any fixed period, but by the circumstances attending each case.

As a proof that the operation is not always necessary, even when circumstances may appear to call for it, the following case, mentioned by the late Sir B. Brodie as having occurred in a French hospital, is of some interest. It is that of a woman whose pelvis was considered to be too small for the egress of the child. As she was at the full term of gestation, the Cæsarean section was proposed; but before the operators were ready to commence, the child was expelled by the natural efforts of the uterus, or, as Sir Benjamin expressed it, "the child preferred coming into the world by the old road!" ("Lancet," Dec. 1853.) This, however, is not the only case of the kind on record. There is great reason to believe that Continental practitioners are too officious in suggesting the performance of this operation, and that it has been often undertaken to the serious risk of the life of a woman, when if left to nature, she would have done well. A case is reported to have occurred in Scotland in 1847, in which the Cæsarean operation was considered by several practitioners of experience to be the only means by which delivery could be accomplished. Fortunately for the woman, the labor was somewhat rapid, and she was delivered of a dead child, weighing about three pounds, before the arrival of those who had considered that the operation would be required. ("Ed. Monthly Jour.," July, 1847, p. 30.) The fact is, on these occasions nature adapts means to ends in a most unexpected manner.

Medical jurists have differed respecting the period of gestation at which the operation should be performed. This would of course depend on the earliest period at which a child might be born capable of living. In reference to tenancy by courtesy, a child might be extracted alive as early as the fifth month, but it would not be likely to survive unless it were at or about the seventh month. When a woman dies undelivered, it is difficult to say for how long a period the child may survive in the uterus. It has been stated that a child may thus continue to live for many hours, but this is not borne out by any facts, and the physician who makes the suggestion admits that no time should be lost in removing it from the uterus. In the case of *L'Hotellier*, above referred to ("Ann. d'Hyg.," 1838, vol. 1, p. 98), the child was removed alive a quarter of an hour after the death of the woman. Dr. Madge operated in a case of convulsions *twenty minutes* after the death of the woman, but the child was then dead. There were no signs of uterine action after the mother's death. ("Amer. Jour. Med. Sci.," July, 1872, p. 585.) Some have alleged, that unless the operation is performed *immediately* after the death of the woman, the child would not be extracted living. The condition of the foetus in utero is, however, peculiar, and quite distinct from that of a child living by the act of breathing. There may be a limited independent survivorship, and the operation may be per-

formed so late as from a quarter to half an hour after the death of the woman, with the probability of extracting a living child. There is no doubt that it will carry with it the greatest chance of success when performed immediately after the circulation between the woman and the child has ceased. This time will be marked by the cessation of the heart's action in the woman. Dr. Lorain recently extracted a child from the body of a woman, æt. thirty-five, in her eighth pregnancy. She died from eclampsia, and immediately after she drew her last breath, the abdomen was opened and a child at full term was extracted. In about a minute it began to breathe. ("Amer. Journ. Med. Sci.," Oct. 1873, p. 561.) In March, 1867, a woman, æt. 25, died of apoplexy in the eighth month of her pregnancy. With the consent of the husband the Cæsarean operation was performed within *five minutes* after the mother's death, and a male child weighing hardly four pounds was extracted. It was seemingly dead, but by artificial respiration life was restored, and the child is reported to have done well. ("Lancet," 1870, vol. 2, p. 87.) Dr. Harris, U. S., in an elaborate paper on the viability of the fœtus after the death of the mother, quotes a case which occurred in the practice of Dr. Blundell at Guy's Hospital. A woman far advanced in pregnancy was run over in the street, and she died in a few minutes after she had reached the hospital. In thirteen minutes after her last respiration the abdominal section was commenced. In *fifteen* the fœtus was out of the uterus and subjected to restorative measures. Its lungs were inflated by means of the tracheal tubes: the warm bath was used and artificial respiration persevered with. In thirteen minutes the child began to breathe a little and the umbilical cord to pulsate, and in time restoration was complete. This writer states that from hundreds of post-mortem Cæsarean operations not one in five infants show any signs of life when the uterus is opened, and not one in ten lives to be delivered. ("Amer. Journ. Med. Sci.," Oct. 1879, p. 389.)

Mr. Buckell, of Winchester, reports a case in which a woman had been dead from *twenty to thirty minutes*. He then performed the Cæsarean section, which occupied only three minutes, and removed the child living. The pulsation of the cord was scarcely perceptible, and the heart acted very feebly. Artificial means were resorted to to establish respiration, and in about an hour they were successful. He refers to ten cases of Cæsarean section, with two recoveries of the mothers: and of six living children recovered, three survived two months. ("Brit. Med. Journ.," Aug. 4, 1877, p. 135.) It has been said that extra-uterine life may be maintained for two hours or more after the death of the mother, but this is very doubtful. The statement rests on no reliable proof.

3. The child must be born capable of inheriting; therefore, if it be a *monster* which cannot legally take an estate, the husband does not acquire a right of tenancy. The connection of teratology or monstrosity with medical jurisprudence has been most ably investigated by M. St.-Hilaire. Although legal questions connected with monstrous births do not often occur, yet it is proper that a medical witness should be acquainted with certain facts respecting them. The law of England has given no precise definition of what is intended by a *monster*. According to Lord Coke, it is a "being which hath not the shape of mankind; such

a being cannot be heir to or inherit land, although brought forth within marriage." A mere deformity in any part of the body, such as supernumerary fingers or toes, twisted or deformed limbs, will not constitute a monster in law, so far as the succession to property is considered, provided the being still have "*human shape*." Even a supernumerary leg would not probably be allowed to avert an inheritance! Various classifications of monsters have been made, but these are of no assistance whatever to a medical jurist, because each case must be decided by the peculiarities attending it; and his duty will not be to state the class and order of the monster, but simply in what respect it differs from a normal human being. In consequence of the want of a sufficient number of precedents on this subject, it is difficult to say what degree of monstrosity would be required in law in order to cut off the civil rights of a being. Monsters may be acephalous (headless), dicephalous (two heads with one body), or disomatous (two bodies with one head). Others again, like the Siamese twins, have two distinct bodies united by a broad band of skin. Would an acephalous monster be considered as devoid of human shape? Would a disomatous monster be allowed to inherit as one?—to marry as one?—or how would legal punishment be inflicted in the event of one of the bodies infringing the laws? Such are the singular questions which have been propounded by medical casuists in relation to these beings; and there is obviously ample room for the exercise of much legal ingenuity in respect to these questions. According to St.-Hilaire, the rule which has been followed in all countries respecting these monstrosities is to consider every monster, with two equally developed heads, whether it be disomatous or not, as two beings; and every monster with a single head, under the same circumstances, as a single being. He ascribes the origin of this rule to the performance of the rite of baptism in all Christian countries upon each head, when the monster is dicephalous. This view appears rational when we consider that with two heads there are two moral individualities; while with a single head, there is one will and one moral individuality. But it is doubtful how far this doctrine would be accepted by jurists and legislators.

The *Siamese twins*, *Chang and Eng*, may be regarded as forming the most remarkable duplex monster of modern times. They were born in 1811, and appeared first in England in 1830, and afterwards in 1869. They were united by a broad thick band, extending from the lower part of the chest bone to the other (cartilage ensiformis). The band was four inches in length, and seven inches in circumference. The nerves and bloodvessels of each met in the centre of it, but there was no direct blood-communication between the two. There were two distinct hearts, the pulses having been observed to differ in frequency and character. The respiration was wholly independent of each other. Their mental operations were entirely distinct, and they were known to differ in opinion on the question of bathing, etc. In short, they were really two distinct men, with the misfortune of having this connecting band between them.

Under the circumstances mentioned, it would have been impossible in relation to civil and criminal jurisprudence to make both responsible for the acts of one. Living for forty years in America, they exercised the rights of citizenship as independent persons, and had married two sisters,

such person had sufficient capacity to know that the act was forbidden by law.

Boys at or under 14 have been tried and convicted of rape on several occasions. Under the new Criminal Code it is provided that there shall henceforth be no presumption of law as to the age at which a boy becomes capable of committing a rape.

A person attains his legal majority, or is completely of age, the first instant of *the day before* the twenty-first anniversary of his birthday, although forty-seven hours and fifty-nine minutes short of the complete number of days counting by hours: and this mode of calculating age and time is applicable to all other ages before and after twenty-one. This is on the principle that a part of a day is, in a legal point of view, equal to the whole of a day. A few minutes or hours may thus determine the attainment of majority, and with this, the responsibility of minors for civil contracts, or the validity of their wills. By 1 Vict., c. 26, no will made by any person under the age of twenty-one years shall be valid; and as the day of a person's birth is included in the computation of his age, and there being in law no fraction of a day, a valid will may be made at any time in the day before that which is usually considered the twenty-first anniversary of birth.

There is another aspect in which this question of age may be viewed—namely, in reference to the responsibility of accused persons for debts, or alleged criminal acts. In *Reg. v. Thornhill* (Stafford Lent Ass., 1865), the prisoner was indicted for a misdemeanor in carnally knowing and abusing one Mary Sambrook, being a girl above the age of 10 and under the age of 12 years. It appeared in evidence that the girl's birthday was on the 5th of December, 1852, and the offence was alleged to have been committed on the 4th of December, 1864. The question then arose whether this girl was at the time under the age of 12 years, so as to bring the offence within the statute. It was objected by the prisoner's counsel, that as on the 5th of December the girl would enter on her 13th year, she had therefore completed her twelfth year on the 4th of December, and that the law did not recognize a fraction of a day in such a case, so that she was 12 years old as much on the first hour of that day as on the last—and his lordship (Pigott, B.) so held. The indictment contained counts alleging rape and assault, but, after the cross examination of the girl, his lordship stopped the case, and the prisoner was acquitted. It is obvious that this principle would equally apply to charges of felony for the carnal knowledge of children until 10 years of age, as well as to the misdemeanor of taking girls under the age of 16 years from the custody of their parents, or of stealing children under the age of 14 years from their parents or guardians. (24 & 25 Vict., c. 100, ss. 50, 51, 55, 56.) The proof of the exact date of birth sometimes rests with a medical man.

The subject of *plural births* has been regarded as appertaining to medical jurisprudence; but I am not aware that there is any case on record in which the evidence of a medical man has been required respecting it. This is a simple question of primogeniture, which has been generally settled by the aid of depositions or declarations of old relations or servants present at the births. Of course, in the absence of eye-wit-

nesses, the question of priority of birth must be a matter of conjecture. It cannot be determined by the size or weight of the child, but it might be determined by the observation of certain marks or deformities in one or more of the children.

LEGITIMACY.

CHAPTER LVI.

PRESUMPTION OF LEGITIMACY.—NATURAL PERIOD OF GESTATION.—DURATION OF PREGNANCY FROM ONE INTERCOURSE.—PREMATURE BIRTHS.—SHORT PERIODS OF GESTATION.—VIABILITY.—EARLIEST PERIOD AT WHICH A CHILD MAY BE BORN LIVING.—EVIDENCE FROM THE STATE OF THE CHILD.—PROTRACTED BIRTHS.—THE PERIOD OF GESTATION NOT FIXED BY LAW.

Legal presumption of legitimacy.—Every child born either in lawful matrimony, or within a period after the death of her husband in accordance with the natural duration of gestation, is considered by the English law to be the child of the husband, unless the contrary be made clearly to appear by medical or moral evidence, or by both combined. [In a recent case in Pennsylvania, *Dennison v. Page* (5 Casey, 420), where a child was born three months after marriage, which the husband instantly disclaimed, and never, during his life, recognized, it was held, that where a child is born during wedlock, of which the mother was visibly pregnant at the marriage, it is presumed, *juris et de jure*, to be the offspring of the husband, and that its illegitimacy cannot be proved by the mother after the husband's death. But see the very able dissenting opinion of Lowrie, J., 1 Grant, 377.—P.] It is only in reference to *medical* evidence that the subject of Legitimacy can here be considered; but it is extremely rare to find a case of this kind determined by medical evidence alone. There are generally circumstances which show that a child whose legitimacy is disputed is the offspring of adultery, while the *medical* facts may be perfectly reconcilable with the supposition that the claimant is the child of the husband. These cases, therefore, have been repeatedly decided from *moral* evidence alone—the medical evidence respecting the period of gestation or physical capacity in the parties, leaving the matter in doubt. The present state of the English law on this subject appears to be this. A child born during marriage is deemed illegitimate when, by good medical or other evidence, it is proved that it was *impossible* for the husband to have been the father—whether from his being under the age of puberty, from his laboring under physical incapacity as a result of age or natural infirmity, or from the length of time which may have elapsed since he could have had

such person had sufficient capacity to know that the act was forbidden by law.

Boys at or under 14 have been tried and convicted of rape on several occasions. Under the new Criminal Code it is provided that there shall henceforth be no presumption of law as to the age at which a boy becomes capable of committing a rape.

A person attains his legal majority, or is completely of age, the first instant of *the day before* the twenty-first anniversary of his birthday, although forty-seven hours and fifty-nine minutes short of the complete number of days counting by hours; and this mode of calculating age and time is applicable to all other ages before and after twenty-one. This is on the principle that a part of a day is, in a legal point of view, equal to the whole of a day. A few minutes or hours may thus determine the attainment of majority, and with this, the responsibility of minors for civil contracts, or the validity of their wills. By 1 Vict., c. 26, no will made by any person under the age of twenty-one years shall be valid; and as the day of a person's birth is included in the computation of his age, and there being in law no fraction of a day, a valid will may be made at any time in the day before that which is usually considered the twenty-first anniversary of birth.

There is another aspect in which this question of age may be viewed—namely, in reference to the responsibility of accused persons for debts, or alleged criminal acts. In *Reg. v. nesses, the question of priority of birth must be a matter of conjecture. It cannot be determined by the size or weight of the child, but it might be determined by the observation of certain marks or deformities in one or more of the children.

LEGITIMACY.

CHAPTER LVI.

PRESUMPTION OF LEGITIMACY.—NATURAL PERIOD OF GESTATION.—DURATION OF PREGNANCY FROM ONE INTERCOURSE.—PREMATURE BIRTHS.—SHORT PERIODS OF GESTATION.—VIABILITY.—EARLIEST PERIOD AT WHICH A CHILD MAY BE BORN LIVING.—EVIDENCE FROM THE STATE OF THE CHILD.—PROTRACTED BIRTHS.—THE PERIOD OF GESTATION NOT FIXED BY LAW.

Legal presumption of legitimacy.—Every child born either in lawful matrimony, or within a period after the death of her husband in accordance with the natural duration of gestation, is considered by the English law to be the child of the husband, unless the contrary be made clearly to appear by medical or moral evidence, or by both combined. [In a recent case in Pennsylvania, *Dennison v. Page* (5 Casey, 420), where a child was born three months after marriage, which the husband instantly disclaimed, and never, during his life, recognized, it was held, that where a child is born during wedlock, of which the mother was visibly pregnant at the marriage, it is presumed, *juris et de jure*, to be the offspring of the husband, and that its illegitimacy cannot be proved by the mother after the husband's death. But see the very able dissenting opinion of Lowrie, J., 1 Grant, 377.—P.] It is only in reference to *medical* evidence that the subject of Legitimacy can here be considered; but it is extremely rare to find a case of this kind determined by medical evidence alone. There are generally circumstances which show that a child whose legitimacy is disputed is the offspring of adultery, while the *medical* facts may be perfectly reconcilable with the supposition that the claimant is the child of the husband. These cases, therefore, have been repeatedly decided from *moral* evidence alone—the medical evidence respecting the period of gestation or physical capacity in the parties, leaving the matter in doubt. The present state of the English law on this subject appears to be this. A child born during marriage is deemed illegitimate when, by good medical or other evidence, it is proved that it was *impossible* for the husband to have been the father—whether from his being under the age of puberty, from his laboring under physical incapacity as a result of age or natural infirmity, or from the length of time which may have elapsed since he could have had

intercourse, whether by reason of absence or death. When the question turns upon any of these conditions, medical science is required for its solution, and on these occasions skilled experts are usually selected by the litigants. With proof of immorality on the part of the wife, so important on these occasions, a medical witness is not in the least concerned.

Access or non-access.—This question is usually left to the jury upon the general evidence adduced; but medical opinions may occasionally assist them in coming to a conclusion. In *Morrall v. Morrall* (Gloucester Winter Ass., 1879), an infant claimed the title to certain property. The defence was that the child was illegitimate, on the ground of non-access on the part of the deceased husband. The mother of the claimant was married in 1865 to S. Morrall. After six years of married life without issue, Morrall was attacked with disease of the brain, and in May, 1871, he was placed under restraint in a lunatic asylum. In this asylum he was occasionally visited by his wife, and he remained there until the day of his death, which occurred on the 3d of September, 1872. On the day following his wife gave birth to a full-grown child, the claimant in this action, and four months after she married one Joseph Nixon, under whose roof she had gone to live on her husband's death, and in whose house the birth of the child in question had taken place.

There was evidence that the wife visited the asylum in January, 1872, in company with a relative of Nixon's. The interview with her husband lasted from twenty minutes to half an hour. No one else was in the room, and the patient was under no restraint. He was rational during the visit, and apparently in good health. There was no other evidence of access. Medical evidence was then given by the physicians of the asylum showing that the opportunities of access arising from an interview between a patient and his wife as described could hardly result in the manner suggested, but that the state of Morrall's physical health at the time that the child must have been begotten rendered it impossible that he could have been the father. In addition to this there was evidence that Nixon had admitted the child to be his, and this admission was confirmed by some correspondence on the part of the widow. The learned judge said that the child having been begotten during lawful wedlock it was presumptively legitimate, and that was so, even if the wife was also during that time committing adultery. It was admitted that the husband and wife did meet at the asylum on the 18th of December, but the question would be under what circumstances that meeting took place, for mere personal access would not be sufficient. The question, therefore, for the jury was: Had the defendant satisfied them that Samuel Morrall, who died on the 4th of September, 1872, had not intercourse with his wife at or about the time when in the ordinary course of nature he might have been the father of the child. They answered this question in the affirmation that there had been no sexual access, and the verdict was entered for the defendant.

In cases of contested legitimacy, the English law does not regard the date of *conception*, which cannot be fixed, but the date of *birth*, which can be fixed. Medical evidence may relate—1st, to the actual length of the period of gestation; this may be in a given case so short

or so long as to render it medically impossible that the husband could be the father. 2dly, there may be physical incapacity in the husband to procreate; he may be too old or too young—or he may labor under some physical defect rendering it impossible that he should be the father. 3dly, there may be sterility or incapacity in the wife, rendering it impossible that the child should be the offspring of a particular woman; in other words, the claimant may be a supposititious child.

Natural period of gestation. Duration from one intercourse.—The first point to be considered is—What is the natural period of gestation, and whether this is a fixed or variable term. According to the testimony of experienced accoucheurs, the average duration of gestation in the human female is comprised between the *thirty-eighth and fortieth weeks* after conception. Numerous facts show that the greater number of children are naturally born between these two periods. Out of 186 cases reported by the late Dr. Murphy, the greater number of deliveries took place on the 285th day (“Obstetric Reports,” 1844); but his opinion is that 301 days may be taken as the average limit of gestation. (“Lancet,” Nov. 11, 1844, p. 284.) Dr. Blundell considered that the average period was 274 days; Sir J. Simpson (*Bromwich v. Waters*, Chester Lent Ass., 1863), 277 days, *i. e.*, nine calendar months and a week; and other accoucheurs of repute have fixed upon 280 days. Among 500 cases observed by the late Dr. Reid, there were 283 in which the period of gestation was within 280 days, and 217 cases in which it went beyond this period. Dr. Duncan found in a group of forty-six cases, that 275 days is the average interval between that which he terms “insemination” (intercourse) and parturition. The largest number of cases on any particular day was seven on the 274th day. (“Edin. Monthly Journal,” 1854, vol. 9, p. 230.) The most common cause of this variation in time is, that the usual mode of calculation, by reference to the suppression of the menstrual discharge, even in a healthy woman, may lead to a possible error of two, three, or even four weeks, since there is no sign whereby, in the majority of women, the actual time of *conception* can be determined. Some have been able to determine by peculiar sensations, the time at which they have conceived; but, as a general rule, this must be a matter of pure conjecture when they are living in connubial intercourse.

On the other hand, accidental and isolated cases have clearly proved that a great difference naturally exists among women with respect to the period of gestation; and it is probable that in no two is it necessarily the same. When there has been only *one* intercourse, the duration of pregnancy may be certainly calculated without reference to any changes in the female constitution: for the date of conception, within certain limits to be presently mentioned, would be fixed. Observations of this kind have shown that women have differed from each other; and in several instances the time has exceeded or fallen short of the period of forty weeks, which has been usually set down as the legal limit of natural gestation. In three cases of one intercourse known to the late Dr. Rigby, labor came on in 260, 264, and 276 days, making a difference of sixteen days. (“Med. Times,” March 14, 1846, p. 471.) In three other instances which were privately communicated to me by Dr. S. W.

J. Merriman, labor commenced at 281, 283, and 286 days respectively after one intercourse; and in a case which occurred to Dr. Reid, the labor did not commence until after the lapse of 293 days from a single intercourse. (“Lancet,” July 20, 1850, p. 79.) In another case accurately observed, communicated to me in March, 1865, the gestation lasted 281 days. Menstruation had ceased on the 16th September, intercourse took place on the 20th, quickening occurred on the 23d January following, and a full-grown male child was born on the 28th June following. In two cases, for which I am indebted to the late Mr. Carrington, the women were delivered respectively in 249 and 260 days after a single intercourse. In a third, in which pregnancy was the result of a rape, there was an interval of 261 days between intercourse and delivery. Hence it will be perceived that in well-observed cases, where there could be no motive for misstatement, and in which the characters of the women, some of whom were married and had already borne children, were beyond the reach of suspicion, a difference of not less than *thirty-three days* has been observed to occur, *i. e.*, between the earliest case reported by Dr. Rigby and the latest reported by Dr. Reid. This is worthy of remark, because in one case (*Luscombe v. Prettyjohn*) it was legally held that 299 days, only six days longer than in Dr. Reid’s observation, was an *impossible* period for human gestation! In addition to the above facts, showing the variability of the period after a single intercourse, the following may be cited. Dr. Macilwain, U. S., has reported a case of gestation, which he thinks must have extended to 296 or at least to 299 days. (“Amer. Jour. Med. Sci.,” July, 1848.) I am indebted to Dr. Oldham for nine cases, which have fallen under his observation, in which the duration of pregnancy from a single intercourse was accurately observed:—

Case.	Days.	Case.	Days.
1	266	6	281
2	268	7	283
3	271	8	284
4	280	9	285
5	280		

It is to be observed of these cases that Nos. 4, 5, and 6 represent the periods of gestation in the same woman at different times.

Dr. Lockwood has published the following as the result of his experience. The actual duration of the term of gestation in the human subject, *i. e.*, the interval between intercourse and delivery, was ascertained by him in four cases:—No. 1, aged 19, duration 272 days (first confinement); No. 2, aged 30 (first confinement), duration 276 days; No. 3, aged 17, duration 270 days; No. 4, aged 44 (seventh confinement), duration 284 days, the child weighing fourteen pounds. (“Brit. Amer. Jour.,” 1847, p. 214.) M. Devilliers has also published the particulars of nine cases, in which the interval from a single intercourse was accurately determined. Delivery took place at the following periods:—229, 246, 257, 267, 301, 276–281, 278–283, 270, and 266–272 days, making an extreme difference of 49 days in the earliest and the latest periods between intercourse and delivery. (“Gaz. Méd.,” March 4, 1848.) Another authority, Dr. Ahlfeld, made his observations on 425

women, whose children seemed mature, and, reckoning from the day of conception he found that the average duration of gestation was 269.9 days. Out of thirty cases of single or well-defined coitus collected by Ahlfeld, gestation varied from 233 days to one case of 313 days. The average of all was 269.17 days, which corresponds closely with the period obtained by other modes of observation. ("Amer. Jour. Med. Sci.," Oct. 1870, p. 566.) Hecker's tables gave an average of 273.5 days. According to a more recent obstetric authority, Dr. Stadtfeldt, of Copenhagen, the mean duration in sixty-five pregnancies observed by him was 271.8 days, and the extent of variation was from 250 to 293 days. ("Brit. Med. Jour.," Oct. 1877, 599.) Dr. Strathy reports a case in the same journal, April, 1876, p. 505, in which a married woman was delivered of a child weighing five pounds, 298 days after the last intercourse with her husband.

There is reason to believe that the *date of conception* after a single intercourse, varies in different women and in the same woman at different times. It is customary for physiologists to date conception from intercourse; but the researches of Bischoff and Raciborski have shown that a variable interval may elapse, according to the situation of the ovum at the time. It has also been supposed that women conceive more readily at some periods than at others, and that intercourse had within eight to twelve days from the cessation of the menstrual discharge is more favorable to conception than at any other period. Dr. Oldham met with a case in which impregnation took place twelve days after menstruation; and he states that he has known it to occur at the respective times of ten days, twelve days, and even twenty-one days after the monthly period; and he knows of no fact to disprove the opinion that the human female is susceptible of impregnation at any time between her monthly periods. According to Dr. Duncan, a single insemination at any period of the interval between two menstrual periods may result in fecundation. ("Edin. Monthly Journal," 1854, vol. 9, p. 233.)

The experience of Dr. Oldham is confirmed by that of the late Dr. Reid. This gentleman admits that impregnation is more likely to occur immediately after the termination of a menstrual period than at any time during the interval. The next most likely period is immediately previous to the occurrence of menstruation, and the probability of conception becomes slighter as the time is more distant from this epoch; but there is no period in the menstrual interval at which impregnation may not occur. ("Lancet," Sept. 3, 1853.) According to Raciborski, from observations made in Paris on one hundred women, no more than six or seven had become impregnated at the mid-term from the menstrual periods. In several cases of single intercourse, the dates being certain, conception took place twelve and fourteen days after menstruation. It may be therefore fairly taken as a fact, irrespective of any modern theories of ovulation, that a woman may conceive from intercourse had at the inter-menstrual period (mid-period), although in a given number of instances, it is probable that the conceptions would be more numerous within six or seven days after the cessation of the menses than at any other time.

In this case it is assumed that intercourse and conception are synchro-

nous, but recent physiological researches have proved that the date of *conception* is not fixed by the date of *intercourse*. The time occupied by the descent of the ovum along the Fallopian tube varies, while the time required for the passage of the male fluid to meet the ovum is also subject to variation. The investigations of Bischoff and Valentin show that the spermatozoa may retain their movements, and probably their fecundating power, for so long a period as *seven days* within the body of a woman. Fecundation cannot result unless the matured ovum meets these bodies in an active or living condition; and conception may be regarded, in the language of Dr. Meigs, as the fixation of a fecundated ovum upon the living surface of the woman. Conception may therefore take place either in a few hours, or, according to Valentin's observations, at so long a period as seven days, after intercourse. But this does not satisfactorily explain such extreme differences as were observed in the cases of Dr. Rigby and Dr. Reid (thirty-three days), or in those of M. Devilliers (forty-nine days)—*ante*, p. 684. We must therefore be prepared to admit, either that conception may in some cases be delayed for so long a period as from five to seven weeks after intercourse, or that there may be a difference of from five to seven weeks in the duration of pregnancy. Whatever may be the explanation adopted, it is obvious that, in a medico-legal view, the only conclusion at which we can arrive is, that the period of gestation in woman is *not*, as it was formerly supposed to be, a fixed and invariable term.

Great mistakes have arisen in the calculation of the period by the use of the word "month"—some intending by this a *lunar*, and others a *calendar* month. Nine lunar months would be equal to 252 days, while the average of nine calendar months would be 270 days—the latter period varying according to the particular months of the year over which the pregnancy might extend. To prevent mistakes or that misunderstanding of evidence which has so frequently arisen, it would be advisable that medical witnesses should always express the period of gestation in weeks or days, concerning which there can be no misunderstanding; it would be also proper to adopt the plan of always commencing the calculation from the period of the last cessation of the menses, rather than from two weeks later. The latter rule is often followed, and this discrepancy is another cause of confusion.

Premature birth. Short periods of gestation.—From the preceding remarks we may regard all births before the thirty-eighth week as premature, and all those which occur after the fortieth week as protracted cases; and one great point for a medical witness to determine is, whether the external characters presented by a child correspond to those which it should present, supposing it to be legitimately born. When the birth is premature, this sort of corroborative evidence may be sometimes obtained; because, assuming that there has been no access between the parties before marriage, children born at the fifth or sixth month after marriage cannot, if the offspring of the husband, present the characters of those born at the full period. It is not so with protracted births, for children are not more developed in protracted cases than they are in those which occur at the usual period. This would lead to the inference that when a child has reached a certain stage of development it ceases to grow—a

view which is borne out by the observations of Dr. Rüttel. (Henke's "Zeitschrift," 1844, p. 247.) This gentleman observed that the size of a child did not increase in proportion to the length of gestation. In protracted human and animal gestation the offspring is not remarkable for size and weight. Thus, robust mothers have had small children, and small mothers strong and sometimes unusually large children. The late Dr. Murphy states that he met with a fully developed child which was born after a gestation of only 251 days. ("Lancet," Nov. 30, 1844, p. 284.) For an account of the characters presented by children at different uterine ages, see INFANTICIDE (p. 596, *ante*).

Development of the child.—In judging from marks of development on the body of a child as a test of uterine age, we must make full allowance for the exceptions to which they are liable. The nearer the supposed premature delivery approaches to the full period of gestation, the more difficult will be the formation of an opinion. Although the characters of a seven-months child, as a general rule, are usually well-marked, and may be known by common observation, it is not possible to distinguish with absolute certainty a child born at the eighth from one born at the ninth month. Burns observes that gestation may be completed, and the child perfected to its natural size, a week or two sooner than the end of the ninth month; and other accoucheurs corroborate this view. (Dr. Murphy, in "Lancet," Nov. 30, 1844, p. 284.)

When, however, the facts are such that to be the offspring of the husband it must be a six-months child, and it is born mature, there can be no reason to doubt that it is illegitimate. (*Eager v. Grimwood*, Exchequer Sittings, Jan. 7, 1847.) But the fact that a child born at nine months is small and resembles in size and weight a seven or eight-months child, cannot be taken as a medical proof of illegitimacy. Children born at the full period vary considerably in size and weight; yet, although small, there is commonly about them an appearance of *development*, which is especially apparent in the features. If there should be a general want of development in the body, and if certain foetal peculiarities remain—as, for example, the membranæ pupillares, or, in the male, the testes do not occupy the scrotum—these facts lead to a strong presumption that the child has not reached the full period. On the other hand, when a child is born with the full signs of maturity about it, at or under seven months from possible access of the husband, there is an equally strong presumption that it is illegitimate. The great progressive stage of development is considered to be during the last two months of gestation—the changes which the foetus undergoes are greater and more marked at this than at any other time. The general opinion is that an eight-months child is not with any certainty to be distinguished from one born at the ninth month. If the body of a child is large and fully developed, it would be considered to have been born at the full period of gestation, and any opinion which had led to the supposition that it was a seven-months child would be attributed to some mistake in the calculation. Dr. Beck states it as barely possible that a child born at seven months may *occasionally* be of such a size as to be considered mature, yet he qualifies this statement by the remark, that the assertion is most frequently made by those whose character is in danger of being destroyed. The important

medical question is, however,—Has a really seven-months child ever been born so developed as to be mistaken by an experienced person for one that was mature? He adduces no case of this kind in support of his opinion. There can be no doubt of the correctness of this statement, that a *mature* child, born *before* seven full months after intercourse, ought to be considered illegitimate; but it would be difficult to maintain this proposition consistently with the above admission, for there is no obvious reason why a child should not acquire premature development during the latter half of the sixth as well as at the seventh month.

In *Bromwich v. Waters* (Chester Lent Ass., 1862) the question of premature development arose incidentally upon an alleged gestation of 259 days. It was stated that intercourse had taken place upon the 9th of November, 1861, and a child was born on the 26th July, 1862—a period of 259 days, or thirty-seven weeks. The child had the appearance of a mature child. The counsel for defendant admitted that a child born at this period, *i. e.*, three weeks before maturity, might be as large as one born at the ninth month, but he denied that it would be so perfectly developed in all its parts. When the question was put to the late Sir J. Simpson, who gave evidence at the trial in favor of the defendant, he said that full size was generally combined with full development; and he further stated that it was against all the laws of nature that children should be born full-grown even a fortnight before the usual term of gestation, which he fixed at nine calendar months and a week. According to this view, if there had been intercourse on the 9th of November, 1861, the day of probable delivery would be a week after the 9th of the following August, *i. e.*, on the 16th August, 1862. Hence, as the child was actually born in a *mature state* on the 26th of July, this was three weeks before the usual term; and therefore, in his opinion, impregnation from some other person had probably taken place three weeks earlier than the period assigned by the woman (Whalley). Sir J. Simpson considered it to be as rare that a child should be born full-grown three weeks before the usual period as that a man should attain one hundred years of age! (“Report of the Trial of *Bromwich v. Waters*,” 1863, p. 33.) There are not many medical witnesses, however, who would venture to affirm that in the last three weeks of gestation there are such marked changes in the body of a child as to render this difference in time always perceptible, or who would venture to bastardize a child or convict a woman of adultery because, when born at the 259th day after intercourse, the child had about it the usual appearances of maturity. This would be equal to affirming that variations in size might take place at the ninth, but not at the eighth month of gestation. But facts are adverse to the theory. Dr. Rüttel, an experienced observer, has met with several instances in which women have been delivered *two* and even *three* weeks before the expiration of the ordinary term (280 days), and the children were as perfectly developed, to all appearance, as other children which had been born at the full period; at any rate they could not be distinguished from them by competent observers.

In another part of this work (INFANTICIDE, p. 597, *ante*), some cases are related which prove that at the ninth month, children are occasionally born of a size and weight greatly exceeding the average. Thus a

nine-months child has been born weighing eighteen pounds, and measuring thirty-two inches, whereas the usual weight is from six to seven pounds, and the length eighteen inches. In such an exceptional case, there is reason to believe that had the child come into the world at the seventh month, it would have appeared to the accoucheur to have reached the full term. As it is impossible to say when such an exception is likely to occur, and a lawyer is always entitled to take advantage of either extreme, it follows that in any case in which this question arises, a witness will be bound to admit that a seven-months child may be born of the average size and weight of a nine-months child, or to give some valid reason for the fact that great variations in size and weight may occur at the ninth, but never at or about the seventh or eighth month of gestation. He must also be prepared to affirm from facts within his knowledge that, in these extreme cases, the doubling of the weight and length of the child is not progressive, but that it suddenly takes place at or near the ninth month. If the child is a male, and the testicles are found in the scrotum, there is every reason to believe that it has passed the seventh and even the eighth month of uterine life. (See INFANTICIDE, p. 597, *ante*.) The differences of opinion among obstetric experts in reference to this question appear to admit of explanation. All will agree that, as a general rule, a seven-months child might be distinguished from a nine-months child, unless the latter was a twin; but at the same time it must be admitted that if variations in development take place at the full term, there is nothing to prevent such variations from occurring at the seventh and eighth months of gestation. Dr. Rigby, who had had a large experience as an accoucheur, said that he had often met with instances of well-developed children born within *seven months* of marriage, but only with the first child. The date of marriage must not, however, always be taken as the date of conception. ("Obstet. Trans.," 1875, p. 227.) Dr. Hicks informs me that he has seen a child born seven months after marriage as large as at the full term; but, as he suggests, this child might really have been begotten so as to be born at the full term. In order to determine this point by unexceptional facts, it would be necessary to collect a series of cases of impregnation from one intercourse, in which the children were born seven months after such intercourse, and were proved to have had the average size and weight of mature children. In the mean time counsel will care little for the rule, but will take every advantage of the existence of admitted exceptions.

Earliest period at which a child may be born living. Viability.—The fact that a child has had the strength to survive its birth for a certain period has been supposed to furnish additional evidence of maturity; for it is well known that under a certain age, children are not born living, or if living they speedily die. Therefore it has been argued, if a child born at the fifth or sixth month after the first cohabitation be born living or survive, this should, *ipso facto*, be taken as a proof of its illegitimacy. According to the English law, it is not necessary that a child, when born, should be capable of living, or *viable*, in order that it should take its civil rights. Thus, it may be born at an early period of gestation—it may be immature, and not likely to survive—or, again, it may be born at the full period of gestation, but it may be obviously laboring under

some defective organization, or some mortal disease, which must necessarily cause its death within a short time after its birth. Fortunately, these points are of no importance in relation to the rights of inheritance; an English medical jurist has only to prove that there was some well-marked physiological sign of *life* after birth. Whether the child was mature or immature, diseased or healthy, is a matter which does not at all enter into the investigation. In this respect our law appears to be more simple and just than that which prevails in France. By Art. 725 of the Code Napoléon, no child that is born alive can inherit unless it is born, as the law terms it, *viable*. The meaning of this word is not defined by the law itself, and there are probably no two lawyers or physicians in that country who place upon it the same interpretation. The French law seems to intend (Devergie, vol. 1, p. 700; Briand, p. 173), by viability in a new-born child, that it should have breathed and be capable of living out of the womb of its mother, and independently of her; also, that it should be capable of living for a longer or shorter period after its birth. It would be difficult for any system of jurisprudence to lay down a more vague or incorrect principle than this; and medical witnesses may consider themselves fortunate that in this country they have not to take part in the unsatisfactory litigation to which such a principle must necessarily give rise.

The question, therefore, to be considered is, What is the *earliest period* of uterine life at which a healthily-formed child can be born living, and with a capacity to live after its birth and to attain maturity? It is now universally admitted that children born at the seventh month of gestation are capable of living, although they are more delicate, and in general require greater care and attention to preserve them than children born at the ninth month; the chances are, however, very much against their surviving. It was the opinion of Dr. William Hunter—and it is one in which most modern authorities concur—that few children born before *seven calendar months* (or 210 days) are capable of living to manhood. They may be born alive at any period between the sixth and seventh months; or even, in some instances, earlier than the sixth: but this is rare; and, if born living, they commonly die soon after birth. There is one case on record, of a child having been born living so early as the *fourth month* of gestation ("Brit. and For. Med. Rev.," vol. 2, p. 236); and another, in which a woman aborted at the fourth and a half month of pregnancy. M. Maisonneuve saw the woman two hours after delivery: he then found the foetus in its membranes, and on laying these open, to his surprise it was still moving. He applied warmth, and succeeded in partially restoring it; for a few minutes the respiratory movements were performed with regularity, but in spite of the establishment of respiration, the child died about six hours after its birth. ("Jour. de Méd.," and "Med. Gaz.," vol. 39, p. 97.) Dr. Ellis brought before the Obstetrical Society a foetus born five months and ten days dating from the last menstrual period (5½ months' gestation). Immediately the child was born it cried so loudly that it was heard downstairs, and continued at intervals to cry as loudly as a full-grown infant. It could not be made warm. It passed meconium, but no urine. It swallowed without trouble. The eyelids were closed. Its weight was

one pound and a quarter, length eleven inches. It lived just forty-four hours. Other cases of a similar kind have been elsewhere described (p. 673). It was said that this child was not *viable*. It had potential life, but it must breathe to be legally alive. ("Brit. Med. Journ.," April, 1874, p. 547.) In two instances of abortion about the *fifth* month, Dr. Davies, of Hertford, noticed that the foetus showed signs of life after its birth, by moving its limbs ("Med. Gaz.," vol. 40, p. 1022); and the following case, in which a child born at the *fifth* month survived upwards of twelve hours, occurred to Mr. Smythe. A woman in her second pregnancy, and in the 147th day of gestation, had severe flooding with rupture of the membranes. Labor occurred on the following night, when a small but well-formed foetus was expelled, giving no other indication of life than a feeble action of the heart, and a strong pulsation in the umbilical cord. It was resuscitated, and *cried* as strongly as a child born at the full period of pregnancy. It weighed less than two pounds, and measured exactly twelve inches. It swallowed some nourishment, but died about twelve hours after birth. The membranæ pupillares were entire, the testicles had not descended, the head was well covered with hair. The length and weight, as well as the presence of hair, indicated a foetus between the sixth and seventh months; but as it is asserted that the period of gestation is accurately given, this must be regarded as an extraordinary instance of premature development. There was clearly nothing in the organization of this child to have prevented its growing to the age of maturity—in other words, it was *viable*. ("Med. Chir. Rev.," July, 1844, p. 266.) In November, 1865, Mr. Carter communicated to me the particulars of a case in which a child was born living at the *fifth month* of gestation. It cried slightly when it was born, and during the half-hour that it was kept unsevered from its mother, it made frequent efforts to breathe. It was perfectly formed. It was about one foot in length, and its weight was fully one pound and a quarter. It died soon after it was born. Mr. Moore has reported a case of a child born living at the fifth month. ("Lancet," Nov. 11, 1865.) A case is reported, in which a child born at five and a half months survived its birth between three and four hours ("Med. Gaz.," vol. 19, p. 165); and on a trial for child-murder (*Reg. v. West*, Nottingham Lent Ass., 1848), a midwife was indicted for causing the death of a child by bringing about the premature delivery of the mother, when she was between the fifth and sixth months of her pregnancy. The child in this instance lived five hours after its birth. Capuron mentions a case in which a child was born at the sixth and a half month of pregnancy, and at the date of the report it was two years old, and enjoyed excellent health. In another instance a child was born at the same period, and lived to the age of ten years. ("Med. Lég. des Acc.," pp. 162, 208.) In a case which fell under my own knowledge, a child was born at the sixth and a half month of gestation, and lived a fortnight. (See another case, "Med. Gaz.," vol. 32, p. 623.) Capuron considers that a child born at the 180th day, or at the sixth month after conception, may be sufficiently mature to live, *i. e.* that there would be no reason to presume it was illegitimate, merely because it survived its premature birth. On the other hand, if born before the sixth month with sufficient maturity

to live, this fact, although by no means a proof, affords, in his opinion, a strong presumption of its illegitimacy. Of eight cases of children born living (by abortion) at the sixth month, Mr. Whitehead states that seven perished within six hours after birth, and one only attained to the age of ten days. ("On Abortion," p. 249.)

Dr. Rüttel, who has examined this subject with great care, states, as the result of his experience, that he attended a married woman, who was afterwards delivered of a living child in the *fifth month* of her pregnancy: the child survived its birth for twenty-four hours. He delivered another woman of twins, in the *sixth month* of her pregnancy: one was dead, and the other continued alive for three hours, its life being indicated only by the visible pulsation of the heart, but there was no perceptible breathing. This fact strongly corroborates the remarks made elsewhere as to life without active respiration (INFANTICIDE, p. 612, *ante*); it has also an immediate bearing on the proof of life in reference to tenancy by courtesy (p. 673, *ante*). In another instance of the birth of male twins, at the *sixth month*, each weighed three pounds. Dr. Rüttel saw them a year after their birth, and they were then two healthy strong children. (Henke's "Zeitschrift der S. A.," 1844, p. 241.) Dr. Barker, of Dumfries, met with a case, in which a female child was born on the 158th day of gestation, or twenty two weeks and four days after intercourse. The size and weight of the child corresponded with the period at which it was born: it weighed one pound and measured eleven inches. It had only rudimentary nails, and very little hair on the back of the head; the eyelids were closed, and remained closed until the second day; the nails were hardly visible; the skin was shrivelled. The child did not suck properly until after the lapse of a month, and she did not walk until she was nineteen months old. When born, the child was wrapped up and placed in a box before the fire. Three and a half years afterwards the child was in a thriving state and healthy, but of small make; she then weighed twenty-nine pounds and a half. ("Med. Times," Sept. 1850, p. 259; also Oct. 12, p. 392.) Mr. Annan, surgeon of Kinross, has recorded a case in which a child was born between the end of the sixth and the middle of the seventh month, and lived for a period of four months and eight days; it weighed a pound and a half when seven days old. ("Med. Times," Sept. 9, 1848, p. 304.) In a case which occurred to Dr. Outrepont, of Bamberg, (reported in Henke's "Zeitschrift," vol. 6), there was the strongest reason to believe that gestation could not have exceeded twenty-seven weeks. The child (a male) weighed, when born, one pound and a half, and measured thirteen and a half inches. The skin was covered with down and much wrinkled—the limbs were small—the nails appeared like white folds of skin, and the testicles had not descended. It breathed as soon as it was born, and by great care its life was preserved. It is singular that its development was very slow until it had reached a period which would have corresponded to the forty-second week of gestation. Dr. Outrepont saw the child when he had attained the age of eleven years, and then he appeared to be of the size of a boy of eight years. The only remarkable point about the case is the length of time which the child lived. In a case quoted in the "Lancet," (Aug. 23, 1851, p.

177), a child born at six months and ten days, was thriving satisfactorily when four months old. (See also "Med. Times," Feb. 16, 1850, p. 129.)

Hence it may be considered as established that children born at the seventh and even at or about the sixth month, may be reared, and that the fact of their surviving for months or years cannot be taken as a proof of illegitimacy. In forming our judgment on these occasions, we are bound to look less at the period at which a child is born, than at the marks of development about the body. The case reported by Mr. Smythe (p. 691, *ante*) is corroborative of this view. Dr. Bonnar has recently published a tabulated view of 112 cases of premature births of living children—the dates of gestation extending from the 120th to the 210th day. Among these cases 35 children died within the first twenty-four hours; 13 more before the completion of one week; 1 in six weeks; 4 in four months. The following lived, or were living at the date of the report: 1, seven and a half months; 8, from one to two years; 1, three and a half years; 5, from ten to fifteen years; 6, to adult age; 5 lived not stated how long. ("Critical Inquiry regarding Superfoetation," 1865, p. 13.)

Protracted births. Long periods of gestation.—The questions connected with retarded gestation have given rise to considerable discussion in legal medicine. That gestation may be retarded or protracted beyond the fortieth week is now, I believe, not disputed by any obstetric writer of reputation. Some accoucheurs have denied it, because they have not met with such cases; but the medico-legal relations of such questions as these do not depend upon the solitary experience of practitioners. It is only by the accumulation of well-ascertained facts from all authentic sources that medical knowledge can be made available for the purposes of the law; otherwise, owing to the mere accident of a witness not having met with any exceptional instances, a court may be entirely misled in its judgment by trusting to his opinion. It is the more important to attend to this, because most of the cases involving questions, either of contested legitimacy or of the chastity of women, turn upon protracted rather than upon premature delivery.

In standard works on Midwifery will be found authentic reports of cases in which gestation continued to the forty-first, forty-second, forty-third, and even to the forty-fourth week. The late Dr. Murphy regarded 301 days, or forty-three weeks, as the average limit of gestation. ("Obstetric Report," p. 4.) Dr. Lee met with a case in which he had no doubt that the pregnancy lasted 287 days; the labor did not take place until forty-one weeks after the departure of the husband of the lady for the West Indies. ("Med. Gaz.," vol. 31, p. 917.) Dr. William Hunter met with two instances in which gestation was protracted until the forty-second week. Dr. Montgomery met with a case in which delivery did not ensue until between the forty-second and forty-fourth weeks. ("Med. Gaz.," vol. 19, p. 646.) Dr. Merriman has published a valuable table on the subject of protracted gestation, on which the most experienced accoucheurs have been in the habit of relying. Of 114 pregnancies calculated by him from the last day at which the women menstruated, and in which the children appeared to be mature, the following were the periods:—

In the 37th week	.	.	.	8	In the 41st week	.	.	.	23
" 38th "	.	.	.	18	" 42d "	.	.	.	15
" 39th "	.	.	.	14	" 43d "	.	.	.	10
" 40th "	.	.	.	33	" 44th "	.	.	.	4

Another well-marked case, occurring forty-four weeks precisely after the cessation of the menses, has been communicated to me by Dr. S. W. J. Merriman.

From these results Dr. Merriman considers that in the greater number of women, gestation is completed in the fortieth week from the cessation of the menses, and next to this period, in the forty-first. In the evidence given by this gentleman in the *Gardner Peerage* case before the House of Lords in 1825, the case of longest protraction on which he was able to rely was that of a married woman, who was in the habit of calculating from the last day on which her monthly period ceased. This lady was delivered 309 days, or forty-four weeks and one day, from the time at which she supposed that she had conceived. In another case mentioned by the witness the period was 303 days, or forty-three weeks and two days from the termination of the last monthly period. It was objected to this evidence, by the Attorney-General, that it was impossible to fix the exact date of conception, and, as the female might have really conceived only a day or two before the expected return of menstruation, twenty-eight days (or four weeks) should be deducted from the periods assigned by the witness. Admitting the validity of this objection—and the fact upon which it is based is indisputable—it followed that the longest protracted case observed by Dr. Merriman might have really been only a case of ordinary gestation extending to forty weeks and one day. An objection of this kind may of course be successively urged in law to any inference from a calculation so made, and it was thus that in the *Gardner Peerage* case the medical evidence failed to render it certain that gestation might be so protracted as to support the legitimacy of the claimant; namely, to 311 days or forty-four weeks and three days. Hence, in considering this question, it is necessary to make full allowance for such a cause of error; and, in calculating the pregnancy from the last day of the last menstrual period, we should deduct the interval of menstruation, if known, and at least twenty-eight days if unknown. In these cases of contested legitimacy the offspring is commonly the result of a *single* intercourse, hence the date of conception is fixed within limits already described (p. 684); and a comparison can be instituted only between the period of gestation thence deduced, and the periods taken in other cases which are equally free from error.

A well-marked case of gestation passing beyond what is commonly set down as the average period, was communicated to me by M. Howell, of Walton-on-Naze. This occurred in a healthy woman, aged 30, who had borne three children, the youngest being 4 years old. She had menstruated with regularity up to the third week in June; the menses then stopped without any apparent cause. Her delivery took place 323 days after their last appearance. Allowing that impregnation occurred at the intermenstrual period, this would make the gestation 309 days; or assuming that impregnation did not occur until twenty-eight days from the date of the last menstruation, this would make the period 295 days, or forty-two weeks and one day.

A case is reported by Dr. Power in his work on "Human Pregnancy," in which gestation is said to have extended to 325 days. Mr. Chattaway, of Knighton, a former pupil, communicated to me the following instance of protracted gestation. A healthy woman, æt. 36, the wife of a farmer, applied to him to attend her in her confinement, which she expected to take place in September, 1856. The menses appeared for the last time in December, 1855, and she quickened in the beginning of April, 1856. About the middle of September (*i. e.*, on the 283d day, dating from the last menstruation) Mr. Chattaway was summoned to attend her, and he found her laboring under severe false pains; there was also a discharge of mucus tinged with blood. The case went on until the 19th November, 1856, when the patient was delivered of a female child of the average size. It would thus appear, according to the ordinary mode of calculation, that deducting twenty-eight days from the last appearance of the menses, gestation was protracted in this instance to 330 days, or forty-seven weeks and one day.

This, of course, is open to the suggestion that the menses had ceased from some accidental cause, and that pregnancy had taken place some weeks subsequently. In reference to this objection, it may be observed that few women have such unusually protracted pregnancies. Then, again, all practitioners may not have met with protracted cases; but the fact being clearly ascertained in one case, it is unnecessary to search for more, unless we doubt the credibility of reporters well qualified to observe, and who could have had no conceivable motive to misrepresent the facts which came before them. On this part of the question I think it is unnecessary to argue. The advocates of a fixed and limitable period differ from each other by a space of at least ten or twelve days, and each must either take his own experience for the final decision of this question, or it must be allowed that men of equal powers of observation with themselves, have met with exceptional instances.

Protracted cases of gestation are always open to the objection that the menstrual function may have been suspended from some hidden morbid cause, one or two months before the actual date of conception, and that there may have been some error in the calculation by which the period has been determined. If, however, the objection is admitted under these circumstances, it would be only equally just to admit that in any given case the ordinary and so-called fixed period, also calculated from the cessation of menstruation, is based on a fallacy. The menstrual function may have accidentally ceased, or continued for several intervals after conception, and thus a corresponding change should be made in fixing the ordinary period of gestation. This view of the question implies that no reliance can be placed on the date of the cessation of the menses as evidence of the actual duration of pregnancy, whether natural, premature, or protracted. My colleague, Dr. Hicks, informs me that he met with a case in which the pregnancy of a woman appeared to be protracted to between twelve and thirteen months. There was every reason to believe that this woman became pregnant during the absence of the menses, and that these had been suspended for some time before intercourse took place. This is no

doubt the explanation of a large number of cases of alleged protracted gestation.

In the *Gardner Peerage* case, the Attorney-General was quite willing to rely upon the cessation of the menstrual discharge as a good criterion of the duration of pregnancy, when by such a mode of calculation this was not made to exceed forty weeks, and thus fitted in with his own view of the case! But it is obvious that this condition must be either taken or rejected altogether as evidence: if taken, we have no right, in alleged protracted cases, to refer the suppression to disease, for the sake of shortening the period, when in ordinary cases we do not refer its continuance to disease, because this would tend to lengthen it: if rejected, it would be in the highest degree unjust not to give to a claimant the beneficial presumption of his having been born legitimate, when the cases adduced in evidence against his claim, are actually based upon a precisely similar mode of calculation!

It is, however, difficult to admit that all the protracted cases recorded by different observers have depended upon mistakes being made in the calculation of the period, since this calculation is based on the same principles as those adopted in cases of ordinary pregnancy. Hence, if there is a mistake in the one case, there would be in the other; if an error in the exception, there would be an error in the rule. Either the average term of pregnancy is wrongly calculated by most accoucheurs at the thirty-eighth or fortieth week, or it is rightly calculated to extend occasionally to the forty-fourth, or, admitting these protracted cases, to the *forty-sixth* week. But, even setting aside the obvious answer to an objection of this nature, some of the protracted cases observed were instances of impregnation from a single intercourse; and, making due allowance for the interval for conception, the general inference would not be affected, and no fallacy could have arisen in these cases of protraction from mistakes dependent on the cessation of menstruation.

The late Dr. Reid's conclusions, derived from numerous facts and cases, represent the views of an experienced observer on this much-disputed question. They are—"1. The duration of pregnancy is not altogether a fixed period: it varies somewhat in the human female as it does in the lower orders of animals. 2. This deviation, however, is not to any great extent: the only *certain* data of calculation are those dependent on the *known time of conception* (of intercourse?). 3. The *average* duration of the pregnant state, when calculated from this event, is about 275 days, or it may have a range of from 270 to 280 days. 4. There is no full or satisfactory evidence of gestation having been prolonged beyond 293 days. 5. The Code Napoléon, which allows 300 days, may be regarded as liberal. 6. The menstrual period must generally serve as our guide, in default of some exact knowledge: it is, however, often fallacious, and is only a means of approximation to the probable time of parturition. 7. The fortieth week after the last appearance of the menses is the most likely period, and the forty-first week the next." Dr. Strathy ("Brit. Med. Jour.," April, 1876, p. 505), after giving a case of his own which reached to 298 days after the last intercourse in the married state, refers to reported cases by different authorities, in which the periods were as

follows:—Dr. Bently, 291 days; Mr. Skey, 293; Dr. Macilwain, 293; Dr. Reid, 287 to 293; and Dr. Ashwell, 300.

Dr. Duncan ("Edin. Monthly Journal," 1854, vol. 9, p. 230) draws the following conclusions regarding the duration of pregnancy:—1. That the interval between conception and parturition (the real duration of pregnancy) has not been exactly ascertained in any case. 2. That the average interval between insemination (intercourse) and parturition (commonly called the duration of pregnancy) is 275 days. 3. That the average intervals between the end of menstruation and parturition have no standard length, but vary within certain limits. 4. That while absolute proof of the prolongation of real pregnancy beyond its usual limits is still deficient, there is evidence to establish the probability that it may be protracted beyond such limits to the extent of three or even four weeks.

Mr. Duncan, of Shetland, has fully reported the case of a woman who in her first pregnancy was not delivered until 300 days after the last menstrual period. The second and third pregnancies lasted for about 285 days. In the fourth, to which he especially refers, she carried her child 325 clear days from the last menstruation—the longest period recorded, excepting in one case quoted by Dr. Duncan. ("Med. Times and Gaz.," 1877, p. 712.)

It will be perceived from the conclusions drawn by Dr. Reid, that he admits a variation of 23 days, *i. e.*, from 270 days (the shortest period) to 293 days, the longest known to himself from a single intercourse. There appears to be no valid reason why the variation should not be even greater than that which is here assigned, and why the duration of pregnancy might not extend occasionally to 296 and even to 301 days. It is merely a question of individual experience. An accoucheur who admitted a variation of 23 days, and who had known gestation to be protracted to the 293d day after intercourse, would hesitate to pronounce a child illegitimate merely because it had been born on the 296th or the 300th day after possible access of the husband. There is no doubt a limit to gestation, but it is not in our power to fix it; hence we find obstetric writers of repute adopting periods which have no point of agreement among themselves. Some stop short at 280 days; others, like Dr. Reid, fix the maximum yet known at 293 days; Dr. Murphy allows from his experience at least 324 days; and Dr. Meigs considers that gestation may be continued to twelve months, or 365 days. ("Obstetrics, the Science and the Art," 1849, p. 194.) The fact is, the term has not yet been fixed, even approximately, by medical science: hence, in a disputed case, other circumstances must be looked to in order to lead a court of law to a safe decision. It is at present hopeless to reconcile the conflicting medical opinions which exist on the subject of the duration of pregnancy in the human female. There is, indeed, only one point on which all modern observers agree—namely, that the period cannot be limited to a fixed and invariable number of days or weeks, but that it is liable to variation according to circumstances not fully understood.

In *Renouf v. Eden* (Queen's Bench, March, 1870), an action for seduction, the defendant denied his liability on the ground that the plaintiff, *æt.* 19, was not delivered until 301 days after their last interview. *Med.*

it was a premature case, the child having been *mature* when born. The question then was reduced to this: Was this alleged protracted gestation of 311 days consistent with medical experience? Many medical witnesses, comprising the principal obstetric practitioners in the kingdom, were examined on this point. Their evidence was conflicting, but a majority concurred in the opinion that natural gestation might be protracted to a period which would certainly cover the birth of the alleged illegitimate child. On the moral side of the question, it was clearly proved that Lady Gardner, after the departure of her husband, was living in open adulterous intercourse with a Mr. Jadis; and on this ground Lord Gardner obtained a divorce from her after his return. He subsequently married a second wife, by whom he had the claimant, Alan Legge Gardner. It was contended that the other claimant was really the son of Lady Gardner by Mr. Jadis. The decision of the House was that this claimant was illegitimate, and that the title should descend to the son of the second Lady Gardner.

The decision appears to have been chiefly based on moral circumstances; for had not the first Lady Gardner been living in adultery at the time of her husband's departure, it is highly probable, from the medical evidence bearing strongly that way, that the legitimacy of the child would have been admitted. Morally speaking, the decision could not be impugned, but medically speaking it assumed that gestation could never be protracted to the 311th day after probable intercourse. Considering that conception is not necessarily the immediate result of intercourse (p. 686), and that we have no data for fixing the precise time of its occurrence, this decision could hardly be supported on medical grounds. We should not be justified in affirming that every child born forty-four weeks and three days after the opportunity of intercourse with the husband was *ex necessitate rei* an illegitimate child, and that the wife was an adulteress. It is true that their lordships did not decide directly that the one claimant was illegitimate, because he could not have been born only after 311 days' gestation; but their decision practically led to this result, as the other claimant was pronounced to be the only son and rightful heir of Lord Gardner. Of the seventeen medical experts examined on this occasion, five supported the opinion that the duration of human pregnancy was *limited* to *about* nine calendar months, *i. e.*, for thirty-nine to forty weeks, or from 273 to 280 days—or, strictly speaking, from 270 to 280 days; one of the witnesses, indeed, said from 265 to 280 days. These witnesses, of course, gave a negative to the possibility, unless by miracle, that Henry Fenton Jadis, *alias* Gardner, could have been the product of 311 days' gestation. On the other side, of twelve medical gentlemen, who seemed to agree with respect to the above-mentioned period as the natural term of gestation, the greater number maintained the *possibility* of pregnancy being protracted to nine and a half, ten, or even eleven calendar months, and of course to 311 days—the alleged term of gestation, at which the counter claimant was born—and they thus admitted the possibility that Mr. H. F. Jadis, *alias* Gardner, might be a ten-and-a-half months' child. (Lyall's "Med. Evid. on the Duration of Pregnancy," etc., p. 8.)

M. Stolz, a recent writer on the subject, after stating that the ordinary

period of gestation is from 270 to 280 days, admits that it may extend to a fortnight beyond the latter period, but not longer, whatever may be the circumstances to cause protraction. Protracted labor, extending over five or six days, must not be included in this term. The death of a child may favor its retention in utero, and thus add to the apparent length of gestation.

The Code Napoléon cuts short all difficulties respecting the period of gestation, in cases of contested legitimacy, by fixing upon the term of 180 days after marriage, and 300 days after dissolution of marriage or non-access, between which periods children born may be regarded as legitimate. In Germany it is laid down that gestation may be protracted from 301 to 308 days, but not beyond. The general law of Germany places the period for ordinary gestation among women not married, at 285 days, but for a married woman divorced, or whose husband has died, it allows 302 days. Hohl, who records these facts, thinks that there is injustice in this fixed rule regarding time, and that in exceptional cases a period of from 322 to 336 days might be admitted. ("Ann. d'Hyg.," 1873, vol. 2, p. 153.) It is more reasonable and just to leave the question open, than to assign an arbitrary period, to which there must necessarily be numerous exceptions.

P A T E R N I T Y.

CHAPTER LVII.

DISPUTED PATERNITY.—PARENTAL LIKENESS.—AFFILIATION.—POSTHUMOUS CHILDREN.—SUPERFŒTATION IN RELATION TO LEGITIMACY.—SUPERSTITIOUS CHILDREN.—SEXUAL MALFORMATIONS.

Disputed paternity. Parental likeness.—It has been stated that the law does not pretend to determine who begat a child when it has been born during wedlock, and from circumstances it might be the child either of the husband or of an adulterer. But medical jurists have recommended that family likeness should be looked to on these occasions,—not merely a likeness in *feature* and figure, but in gesture and other personal peculiarities which may have characterized the alleged parent. These are called questions of *paternity*: they seldom occur except in reference to cases of bastardy, and when they do present themselves, the evidence thus produced, even if affirmative, is properly regarded as only corroborative. In the *Townshend Peerage* case (House of Lords, May, 1843), a presumption based on family likeness was admitted by their lordships. The person whose legitimacy was in question was sworn by one of the

witnesses, to bear so strong a likeness as a child to the alleged adulterer, that he should have known him among five hundred children.

The proceedings in the *Douglas Peerage* case (1767-9) show that evidence of this kind is occasionally of some importance. The peerage was claimed by Archibald Douglas—the survivor of two brothers after the death of the alleged parents, Sir John and Lady Douglas. The claim was disputed, on the ground that the appellant and his deceased brother were supposititious children. Evidence for and against the legitimacy of the claimant had been collected from every quarter, and after it had been most minutely sifted and criticized, the case came on for judgment, in the Court of Session in Scotland, on the 7th of July, 1767. So important was the cause deemed, that the fifteen judges took eight days to deliver their opinions. The result was that seven of the judges voted in favor of the identity or legitimacy of Mr. Stewart, and seven against it; the Lord President, who had the casting vote, agreed with the latter, by which Archibald Douglas, *alias* Stewart, was cast on the world without either name or estate—thus furnishing one among numerous instances that learned judges as well as doctors can differ with precisely the same facts before them! An appeal from this decision was taken to the House of Lords, by which the judgment of the Court of Session was reversed in 1769, and Archibald Stewart (or Douglas) declared to be the undoubted son of Lady Jane, the sister of the previous holder of the title. Much stress was laid, in favor of the legitimacy of these children, on the fact that they closely resembled—the one Sir John, and the other Lady Douglas. The resemblance was said to be general; it was evident in their features, gestures, and habits. Lord Mansfield, in delivering judgment, made the following remarks, which comprise all that can be said on this subject: “I have always considered likeness as an argument of a child being the son of a parent, and the rather as the distinction between individuals in the human species is more discernible than among animals. A man may survey ten thousand people before he sees two faces exactly alike; and in an army of a hundred thousand men, every man may be known from another. If there should be a likeness of feature, there may be a difference in the voice, gesture, or other characters, whereas a family likeness runs generally through all of these: for in everything there is a resemblance, as of feature, voice, attitude, and action.” This kind of evidence has been objected to from its uncertainty; and I am informed, on good authority, that it was in this instance much disputed whether one of the children did resemble Lady Douglas; but it seems to have been generally admitted that the other child resembled the husband, Sir John. From this account it will be seen that evidence from family likeness is not strictly medico-legal; it can be furnished only by friends and relatives who have known the parties well, and are competent to speak of the facts from personal acquaintance with them. It will also be apparent that the affirmative evidence in such cases will be stronger than that which is negative, for it could hardly be inferred that a person was illegitimate because he did not resemble his parent.

The view taken by Lord Mansfield is based on physiological truth. The resemblance is not in features only, but in gesture—in the mode of

walking, sitting, or running, and in certain habits which are really inherited, for they appear in the child when it has reached manhood, although the child may have had no knowledge of its parent.

One of the witnesses in the *Tichborne* case (*Reg. v. Castro or Orton*, May, 1873), speaking to the identity of the claimant with Arthur Orton, chiefly relied on these grounds. He had known the Orton family for many years, and knew Arthur (the claimant) from his infancy up to the time of his leaving England in 1852. In 1870 he saw the claimant, then representing himself as Roger Tichborne, but the witness at once recognized him as the Arthur Orton whom he had known as a child, a boy, and a young man. When cross-examined on his reasons for this strong opinion after the lapse of many years, he said he had formed his opinion "not from likeness of features alone, but from the whole appearance of the man—his figure, his tone of voice, his features, all confirmed it, and, in fact, he could see no real difference." Other witnesses deposed that he had the features, voice, and figure of the father of Arthur Orton.

Parental likeness may be occasionally indicated by color or peculiarities belonging to the varieties of mankind, as of the intermixture of the negro or Mongolian with one of the Caucasian variety. In such a case the evidence afforded becomes much stronger; and supposing that two men of different varieties have had intercourse about the same time with the same woman, the color of the skin of the offspring might enable a court to determine the question of paternity. It is stated to have happened, on more than one occasion, that a black woman has given birth at the same time to a black child and a mulatto; Dr. Cunningham refers to a case in which a negress gave birth to twins, one a black and the other a white child. ("Lancet," May 9, 1846, p. 525.) This was probably a case of superconception. In *Stothard v. Aldridge* (Bail Court, January, 1856), the plaintiff sued the defendant for damages for the seduction of his wife. The defendant was a man of color, and the child born of the alleged adulterous intercourse, was proved by the medical witness to have been born colored and with woolly hair. The husband and wife were both light. This peculiarity fixed the paternity of the child on the black defendant.

Personal *deformities* are not necessarily transmitted from parent to child: yet it would appear, from the subjoined case, that a disputed question of affiliation has been settled on this principle. A woman alleged that a gentleman in whose service she had lived, was the father of a child of which she had been recently delivered. The solicitor who appeared to support the affiliation, rested his case chiefly on the fact that the child had been born with five fingers and a thumb on the right hand, the defendant himself having been born with a similar malformation on both of his hands. It was argued, on the other side, that the deformity might have arisen from the mother's imagination, as, while pregnant, she was constantly in the habit of seeing the defendant. The magistrates decided that he was the father of the child, and condemned him to pay the necessary expenses for its support. ("Med. Times," March 6, 1847, p. 47.) It is very likely that the decision was here influenced by moral circumstances, for otherwise the defendant might

have been the victim of a coincidence. Six-fingered children are, it is well known, born occasionally of five-fingered parents: and as the deformity existed only on one hand in the child, while it was on both hands in the parent, the medical proof that it was actually transmitted by generation was certainly not clearly made out. In some instances attempts have been made to fix the paternity of a child by the *color of the hair*, but this evidence is far less conclusive than that afforded by the color of the skin. In the case of *Frazer v. Bagley* (Feb. 1844) it was alleged that the wife of the plaintiff had had criminal intercourse with the defendant, and the last two children were stated to be the offspring of the latter. The plaintiff and his wife had dark hair, as well as all the children with the exception of the two last: these had red hair, and it was further proved that the defendant had red whiskers and sandy hair. No particular stress was laid upon this evidence, but it was received as a kind of indirect proof. Not much confidence can be placed in facts of this description, since red-haired children are often born to parents who have dark hair; and in one case the children born in wedlock were observed to have dark and red hair alternately.

Affiliation.—Questions of paternity are involved in those relating to *affiliation*. A man may allege that he is not the father of a particular child, by reason of certain circumstances upon which a medical opinion may be required. The necessary transmission of gonorrhœa or syphilis by intercourse may thus become a medical question. In September, 1844, a man was required, under the law of bastardy, to support two children alleged by a woman to be his; the time of gestation was within nine months. The accused denied that he had had intercourse with the defendant, or that he could have been the father, since he was at the time under medical treatment for the venereal disease. The medical questions may therefore assume this shape:—1. Are these diseases invariably transmitted by intercourse? 2. Do they interfere with the act of procreation? Under common circumstances they must both be answered in the negative.

A singular case of bastardy is reported to have occurred in Appenzell, Switzerland. The question was, which of two persons, who had had intercourse with the same woman within a period of *seventeen days*, was the father of an illegitimate child borne by the woman? The council, to which the case was referred, gravely resolved to postpone their decision until the features of the child were so far developed as to enable them to decide from *paternal likeness*. The equity of this difficult case would have been met by compelling each man to contribute to the support of the child! (Schneider's "Annalen der Staatsarzneikunde," 1836, 1 B. s. 470.) The following, which is a more doubtful case, was the subject of a communication to the "Lancet" (March 13, 1847, p. 336):—Two men, A and B, had intercourse, unknown to each other, with a young woman of delicate health; and after this had continued for some years, she was delivered of a female child—nine calendar months and three days after sexual intercourse with A, and nine calendar months, less five days, after similar intercourse with B; or at the end of 279 days after intercourse with A, and at the end of 271 days after intercourse with B:—that is, a period of *eight days* elapsed between the

periods of intercourse with the two men. The woman had no menstrual discharge in the mean time, and it is not believed that she knew any other man; she went her full time, had a good labor, and produced a fine healthy girl; she had a plentiful supply of milk, and enjoyed better health during her pregnancy and suckling than at any other time. The woman died, and the circumstances of the mixed intercourse having become known to A and B, they both refused to maintain the child. A contended that, as the woman was not delivered until nine months and three days after the connection with him, it was physically impossible the child could be his. B contended, on the other hand, that 280 days, and not nine months, is the period of gestation; and that the child having been born 279 days after connection with A, and only 271 days after connection with B, it was therefore probable that the child was begotten by A. There was no perceptible likeness to either of the men in the child, but a marked likeness to the mother. It is obvious from the remarks elsewhere made (*ante*, p. 693), that the periods of 271 and 279 days are comprised within the ordinary range of gestation: hence there would be no *medical* ground for affiliating the child to one more than the other. When two men have had intercourse with the same woman on the same day, it is impossible to settle the paternity except by the accident of likeness; as in the former case, justice to the offspring and to each possible father requires that each should be bound to support the child. In cases of affiliation under the law of bastardy, the evidence of the mother, if corroborated, is received in support of a question of disputed paternity; but sometimes these cases are decided by the length of the period of gestation. A man may prove, or a woman may state, that the intercourse took place at such a remote period as to be inconsistent with the ordinary duration of pregnancy. On this point some remarks have been made elsewhere (*ante*, p. 700). In the United States it appears that very long dates are allowed in bastardy cases; while in this country the tendency is to reject medical evidence altogether. In a case at Cheltenham (July, 1853) the date of intercourse was proved to have been 319 days before the birth of the child. The medical evidence on the whole was in favor of this protraction—one of the witnesses having met with two cases in which gestation was protracted, as he believed, to 310 days from intercourse,—but the case was summarily dismissed.

These questions of affiliation, when the interval is less than six or eight weeks, can rarely be determined by medical evidence; in a twin-case, it would be only just that one should be affiliated to each individual. In a recent case of affiliation, an attempt was made to set aside the order of a magistrate fixing the paternity on the putative father, on the ground that, as the intercourse was had and the child conceived in France, although born in England, it was removed from the jurisdiction of an English magistrate, and should be left to the French courts. The objection was properly overruled, and the alleged father was ordered to pay the usual sum for maintenance. The place of birth should properly fix the liability, as any other rule would be too vague. From what has been elsewhere stated it will be perceived that intercourse might take place in Scotland followed by conception in England and birth in Ireland.

So that there is a due relation between the date of intercourse and the date of birth, no other proof is required.

Posthumous children.—It has been supposed that a case involving a question of paternity might present itself on the marriage of a widow soon after the death of her first husband. If a child were born after the lapse of ten months, it might be a question whether it was a child of the first or second marriage—of the dead or of the living husband; and although there might be no dispute concerning its legitimacy, yet it would be difficult to settle its *paternity*. Such a case appears hypothetical. In order that any doubt should exist, a woman must marry within, at the furthest, *six weeks* after the death of her first husband, or the birth of the child would fall beyond the furthest limit of gestation, so far as he was concerned. The customs of society are, however, a bar to such marriages; and admitting that a child was so born, and that it might be the offspring of either husband, then the fact of its having been born during the marriage of the second husband would presumptively fix the offspring upon him, unless it could be shown that there was no possibility of access on his part. If there was a supposed greater likeness to the first than to the second husband, still this would not be allowed to defeat the legal presumption of the real parentage of the child. It appears to me that evidence much stronger than this would be required for such a purpose. (See Henke's "Zeitschrift," 1838, vol. 2, p. 432.)

Superfœtation in relation to legitimacy.—Most medico-legal writers, in treating legitimacy, have considered it necessary to introduce the subject of superfœtation. By this we are to understand that a second conception may at any time follow the first, and that gestation may go on to its full period in each instance independently of the other; so that if a woman were impregnated when in the third month of gestation, she would bear the first child mature in nine months, and the second child, also mature, at the end of twelve months after the first conception. This subject has been said to involve "not only the conjugal fidelity of a wife, but the disposition of property, and much of the comfort and happiness of society." Its importance to a medical jurist appears to me to have been here considerably exaggerated. So far as I have been able to ascertain, not only is there no legal case involving this question to be met with in the judicial records of this country, but none in reference to this state is ever likely to occur which would create the least practical difficulty. If we admit that a woman may, during marriage, present such a deviation from the common course of nature as to produce two perfectly mature and fully-developed children, the one three or four months after the other, how can such an event be an imputation on her fidelity? Superfœtation, if it occur at all, may occur as readily in married life during connubial intercourse, as among unmarried women. The following appears to be the only possible case wherein a medical opinion might be required respecting this alleged phenomenon. A married woman, six months after the absence or death of her first husband, gives birth to an apparently mature child, that dies; three months afterwards, and nine months after the absence or death of her husband, she may allege that she has given birth to another child, also mature. A medical question may arise, whether two mature children could be so born that

the birth of one should follow three months after the birth of the other; or whether this might not be a case, by no means uncommon, of twin-children—the one being born prematurely, and the other at the full period. (For a case of this kind, at two months' interval, see "Med. Gaz.," vol. 37, p. 27; and for another, at eight days' interval, see the same journal, vol. 47, p. 227; for a third, at thirty-two days' interval, "Am. Journ. Med. Sci.," April, 1845, p. 503.) In one case the abortion of one foetus occurred at the third month, while the other attained the full period. ("Assoc. Medical Journal," November 11, 1853, p. 997.)

Admitting that each child when born was mature and fully developed, and, therefore, that the second child presented a case of superfœtation, the first delivery must have taken place in the presence of witnesses, and it would then have been known whether another child remained in the uterus or not. If the two children were born within the usual period of gestation after the absence or death of the husband, then their legitimacy would be presumed, until the fact of non-access had been clearly established. The mere circumstance of their being apparently mature, and born at different periods, would *per se* furnish no evidence of their illegitimacy. On the other hand, if one or both of them were born out of the ordinary period, then, according to the evidence given, they might or might not be pronounced illegitimate. The law, therefore, appears to have no sort of cognizance of the subject of superfœtation, as such; it is generally merged in the question of protracted gestation, which has already been fully considered (p. 693).

Dr. Bonnar has lately examined the subject of superfœtation in another aspect, and some of the facts which he has brought forward are not consistent with the theory of the births of twins at different intervals. ("A Critical Inquiry regarding Superfœtation, with Cases," 1865.) The first question to which his researches were directed was,—At what period after parturition are the female procreative organs capable of again exercising their functions? It has been supposed that a period of thirty days must elapse in order to enable the organs to reacquire procreative power; but, according to Dr. Bonnar, the earliest period may be taken at the *fourteenth day* after delivery. Impregnation is not likely to take place until the organs have resumed their natural condition, and this will depend on the disappearance of the signs of recent delivery—such as the tender and swollen state of the vagina, the enlargement of the uterus with its relaxed mouth, and the lochial discharge. The persistence of the lochial discharge, the average duration of which after delivery Dr. Bonnar considers to be from one to three or four weeks, is of the greatest importance, as it is most likely to interfere with impregnation. The time for the restoration of the sexual organs to their natural state varies in different women, so that the date for re-impregnation must be more or less conjectural.

It has been usually considered that after the second or third month of pregnancy the cavity of the uterus is so sealed up in the development of the embryo as a result of impregnation, that it is impossible that any fruitful intercourse can take place. In two instances, however, according to Dr. Bonnar, viable children were born of the same woman at five-and-

a-half and four months respectively after the first delivery. On the theory of superconception the uterine organs must have been susceptible of a second impregnation up to the fourth month of gestation. But if the children were not born mature, the power of re-impregnation must have existed for one or two months longer than the period usually assigned—*i. e.* up to the fifth and sixth month of a pregnancy already existing. These researches may help to explain some legal difficulties which have occurred in reference to gestation. They furnish a curious comment upon the suggestion made by some medical jurists, that superfoetation involves the conjugal fidelity of a wife, for no suspicion of illegitimacy could be for a moment entertained simply on account of the shortness of the interval between the two deliveries of the same married woman.

Supposititious children.—Another medico-legal case, in relation to legitimacy, occurs when a woman feigns delivery, and represents the child of another person to be her offspring. She may substitute the living child of another woman for a dead child of which she herself has been delivered, or for a mole which may have passed from her. So, again, a male may be substituted for a female child, and *vice versa*. The practising of a fraud of this nature may seriously affect the rights of inheritance of parties; but it cannot be accomplished without great dexterity and cunning, or without the co-operation of one or more accomplices. Frauds of this kind have, in general, been committed by the aid of a low class of midwives. One instance occurred at Chelsea, in July, 1842, where the fraud was brought to light by the death of the supposititious child. The calling-in of a professional man would infallibly lead to discovery, when the question was simply whether delivery had or had not taken place; but if it be alleged that one living child has been substituted for another, the proof of this can depend on medical evidence, only when the age of the supposititious child does not happen to correspond to the date of the pretended delivery. (See “Ann. d’Hyg.,” 1829, vol. 2, p. 227.) The legitimacy of the claimant of the Douglas Peerage was disputed on this ground, but apparently without foundation. A remarkable case of this description will be found in Henke’s “Zeitschrift der S. A.” (1845, vol. 2, p. 172); and a trial took place some years since in England, involving the alleged substitution of a child, but requiring no medical evidence for its elucidation. (*Day v. Day*, Leicester Lent Ass., 1845.) In another case it was proved that a woman had substituted a doll for the dead body of a child of which she pretended she had been delivered. In a case mentioned by Dr. Chevers, one *Mussamat Janoo*, a midwife of Hissar, being employed to attend a woman in her confinement, persuaded her that the child of which she had been delivered was a monster with two heads, not fit to be looked at: she afterwards said that it was dead, and she would take it away and bury it. She accordingly went away. Next morning, the midwife’s services being required, she was sent for. She excused herself from going under the pretence that she (the midwife) had just been delivered of a child. This improbable story excited suspicion, and the police were called in: she declared that the child was her own. This she also maintained at the trial. It appeared, however, from the evidence of midwives who examined her shortly after the discovery of the child in her house, and also by the deposition of the civil

surgeon, that she exhibited no signs of recent delivery. Several of the neighbors who were constantly in the habit of seeing her, deposed that she had not exhibited any outward signs of pregnancy. She did not attempt to prove how she had disposed of the body of the child which she alleged had died immediately after its birth. She was convicted, and sentenced to imprisonment for seven years. ("Med. Jur. for India," p. 515, from the "Nizamut Adawlut Reports," 26th April, 1853.)

Cases involving a question of substitution are not very common. One of these (*Hutchins v. Hutchins*) was heard in the Vice-Chancellor's Court in May, 1851; and in this the amount of ingenuity required to perpetrate the fraud was only equalled by the skill with which the facts were exposed, and justice ultimately done to the rightful claimant. In another (*Gedney v. Smith*, Rolls Court, Nov. 1864) the fraud was nearly successful, and, but for the dying declaration of the woman herself, would probably have escaped detection and exposure.

A more daring attempt of this kind came before the House of Lords in 1870, in reference to a claim for the earldom of Wicklow (*The Wicklow Peerage case*, Committee for Privileges, April 1, 1870). The title and estate of the Earl of Wicklow passed at his death to his brother's issue. The first in succession was George Howard, who, after a career of dissipation, had died in October, 1864. He had been married in February, 1863, to Ellen Richardson, the daughter of a gentleman's coachman. In default of issue, the estate devolved on his brother Charles, the second in succession. Ellen Howard produced a male child who, she alleged, was born on the 16th May, 1864, and who, if such were the case, would be the rightful Earl. No medical man and no nurse attended Mrs. Howard, although it was her first confinement, and the infant was a seven months' child. It was never registered, and never baptized. There was further strong evidence that she had not borne a child, and that the child which she had produced as her own was obtained by her in August, 1864, from a girl who had been recently delivered in the Liverpool workhouse. Mrs. Howard was clearly identified as the person who had taken away a child at this time. Her story was thus proved to be false. The House of Lords decided against the claim, and came to the conclusion that the witnesses had been guilty of perjury.

In the more recent case of *Lady Gooch* (Nov. 1878) who was charged with fraudulently attempting to pass off a child as that of her husband, the facts were so clear that they almost suggested a doubt whether her conduct was not owing to some insane delusion. She endeavored to persuade a medical man to give a false certificate that she had borne a child, and she induced a nurse to procure a child and to give the appearance of a delivery while she was staying at a London hotel. A medical man who was called in examined her, and found that she had not been delivered of a child, and that the child produced as recently born, was about two weeks old. To carry off her fictitious pregnancy, she had worn pads to her abdomen. These proceedings had been carried on in spite of the remonstrances of a female attendant and her usual medical advisors, as well as the refusal of her husband to admit that she was pregnant. She was committed for trial, but the grand jury ignored the

bill, probably thinking that if fraud had been really intended, the accused would have been more secret in her operations. The medical men on this occasion acted with a due regard to the honor of the profession and their own reputations.

A case in which an attempt was made to pass off a child as that of a woman whose husband had recently died, is reported by Dr. Balfour ("Brit. Med. Journal," Feb. 14, 1880, p. 241). The plot was artfully laid but entirely failed; the state of the umbilical cord of the substituted child did not correspond with the alleged date of delivery of the woman.

The cases that have hitherto been tried, illustrate the importance of accurate observation on the part of medical men in their practice as accoucheurs. Notes of all cases should be made and preserved, including dates of attendance, &c.—daily symptoms and treatment. This should be an invariable rule when a medical man is suddenly called upon to attend, in her confinement, a woman who may not have previously consulted him. If he has had no previous knowledge of the pregnancy of a woman, and if, when he arrives, the child is said to have been born and is in the hands of a nurse, he should most distinctly satisfy himself, by a personal examination, that the woman has been actually delivered. He should also observe whether the child presents the appearance of a new-born child in reference to the state of the skin, the appearance of the cut navel-string, and other circumstances. It is an awkward exposure for a medical man to hear at a trial many years afterwards, that his patient was *not* delivered of a child, that a post-mortem examination of her body had shown that she had never borne a child, and that the supposed new-born babe was, at the date of his first visit, several days old—in short, to find that he himself has been cleverly made to give support to a fraud!

Sexual malformation.—The legitimacy of a child is open to be contested under other circumstances than those connected with the duration of gestation. The alleged parent may have labored under *physical incapacity*: if a male, he may have been affected with impotency—if a female, she may have labored under sterility; and if either of these conditions be proved, the illegitimacy of a child will be established, although the alleged period of gestation may be comprised within the ordinary limits. The sexual conditions now about to be considered have also important bearings in relation to divorce, and occasionally to the civil rights of a child that may be the subject of the malformation. One of the most common and obvious causes of impotency or sterility is malformation of the sexual organs, to which species of monstrosity the term *Hermaphroditism* is commonly applied.

Owing to arrested development, during the growth of the foetus, the sexual organs, which can scarcely be distinguished at the fourth month, occasionally assume an abnormal arrangement. These organs appear to be at that time more or less mixed; and sometimes the male and at others the female characters predominate. With this defective sexual development, the other peculiarities of the sexes are either wanting, or more or less blended. When the being has the general characters of a male with malformation of the generative organs, it is called *androgynus*

—when the characters are those of a female with a like malformation, *androgyna*. There can be no difficulty in identifying such cases, and, according to the degree of malformation, a medical jurist can have no hesitation in pronouncing these persons to be physically impotent. The organs are commonly so defective as to be wholly unfitted for the functions of either sex. It is not intended to be said that it is in all cases easy to assign the sex, but this is of minor importance: the main question is, whether the malformation is or is not such as to justify divorce, or to throw the imputation of illegitimacy upon children claiming to be the offspring of these beings.

Distinction of sex.—The determination of *sex* in these cases of *deformity* has been considered to be necessary under certain circumstances; as when, for instance, a title or entailed inheritance of lands is in question. Lord Coke has stated that, according to the law of England, an hermaphrodite may be either male or female, and it shall succeed according to the kind of sex which doth prevail. Thus it is obvious that the law will decide each case according to the special circumstances proved, but it must not be supposed that the decision is so easy as Lord Coke's dictum would imply. There are many cases in which neither sex can be said to prevail: the beings are positively neuter. The chief character of the male consists in the presence of testicles, and of the female in the presence of a uterus and ovaries; but in one instance both the testicles and the ovaries were wanting; there were essential characters of either sex, and during life it would have been impossible to say whether this being was male or female. (Cormack's "Monthly Journal," July, 1845, p. 492.) In the same journal (page 531) is reported another case, in which, notwithstanding the *external* resemblance to a female, the presence of one testicle in a scrotum showed that the being was of the male sex: yet this person passed for a woman until he had reached his 26th year! It is rare that there is external malformation without internal defect, but even when the female character preponderates, it is not improbable that the uterus or the ovaries may be absent, or the former may be malformed. Such beings are not known to menstruate; and even if there be capacity for intercourse, they are permanently sterile. Sexual desires are, however, commonly absent.

When the person is young, mistakes respecting the sex are more common than at an advanced period of life. As soon as the age of puberty is passed, certain changes take place in the configuration of the body, which may aid a medical practitioner in forming an opinion. Thus, a grave tone of voice, the presence of a beard, the width of the shoulders and narrowness of the pelvis will indicate, *cæteris paribus*, the male sex: while, when these conditions are absent, and there is a rotundity of the members, with want of prominence in the muscles, and a development of the mammæ, we may pronounce upon the female sex predominating. Although no testicles are apparent, still the being may be of the male sex, since it is well known that in persons otherwise well formed these organs occasionally do not descend to occupy the scrotum. Dr. Harris, of Clarksville, has related a singular case, in which, although no testicles could be found, there was a short but naturally-formed penis, through which the being regularly menstruated! The female character predomi-

nated in the corporeal development, and there was the rudiment of a vagina ("Med. Gaz.," vol. xl. p. 562). The fact that the being menstruated was here sufficient to assign it to the female sex. How easily mistakes may be made in the sex of young children is shown by a case which occurred to Mr. Terry, and is quoted in "Cormack's Journal" (April, 1845, p. 307). The child was christened as a female, and was so considered by the parents for two months, when, owing to some defect in the passage of the urine, it was brought to Mr. Terry, and he found there was a malformation of the penis—no vagina, a scrotum with one testicle down and the other descending. He therefore pronounced it to be a male, and its costume was altered accordingly. Another case occurred within my knowledge in 1872, in which a boy had been christened and brought up as a girl up to the age of 13, when, in consequence of a change in the voice and certain masculine habits, some doubts arose about the sex. On consultation with Sir W. Ferguson, he pronounced the child to be of the male sex, and its name and dress were altered accordingly. The testicles were retained in the abdomen, and this probably deceived the accoucheur and the nurse at the time of the birth.

A case of doubtful sex occurred to Dr. Flume. The bodily formation was that of a male, and the external organs presented chiefly the male characters; but on an inspection, there were found a uterus with ovaries and Fallopian tubes. This being had never menstruated. This writer thinks that the shape of the pelvis furnishes the best criterion of the sex. ("American Journal Med. Sci.," 1872, p. 512.)

In a paper published in the "Guy's Hospital Reports," 1867 (p. 419), Mr. Bryant has described various malformations of the sexual organs. In one of these there was an entire absence of vagina, and in another a great development of the clitoris, causing it to resemble the male organ. There were a glans and prepuce, the latter being very large. There was a depression, but no urethra, in the usual situation of the urethral organ.

The presence of a beard and whiskers is usually considered to characterize a male, but the growth of hair on the chin and face is sometimes as profuse in women as in men. Dr. Chowne examined a female named *Joseph Boisdechine*, on behalf of a man who was about to marry her, but who required a certificate as to the real sex of his intended wife before he entered into a matrimonial engagement! Dr. Chowne found nothing in her external conformation indicative of doubtful sex. The breasts were large and full, and the only resemblance to a male was in the abundance of beard and profuse whiskers. The upper lip was free from hair. (See "Lancet," Oct. 11, 1851, p. 335; Jan. 15, 1853, p. 66; "Med. Times and Gaz.," Jan. 15, 1853, p. 71.) Dr. Chowne has published a full account of this case in the "Lancet" for May 1, 1852 (p. 421). He has appended an engraving, which displays the female beard and whiskers. It is stated that this female was born with a quantity of hair on her chin, and that at eight years of age the beard was two inches long! In some instances this growth of hair in women is connected with sexual malformation. I have known an instance in which a Russian countess had so much hair upon her chin that she was

obliged to shave like a man. The following case of hairy development in a woman has been reported by Dr. Hills: M. C., æt. 42, dressmaker, suffering from mania, was admitted into the Norfolk Asylum, 1865. She had a vigorous growth of hair on the lips and chin, for which depilatories had been used, but these made matters worse. The upper part of the body is masculine in form, and the breasts are undeveloped, as in the male sex. The lower part of the body is feminine in outline, and the voice has the feminine tone and character. The clitoris was largely developed, having a distinct prepuce. There were no testicles in the labia, or in the inguinal canals. There was a distinct vagina, and the finger appeared to touch an os uteri. At an early age she had the slightest possible signs of menstruation on three consecutive occasions. In her girlhood she would not associate with other children. While in the asylum she evinced strong sexual passions, and behaved indecently to the attendants. She had thick mustaches, and a full beard. ("Lancet," June 25, 1873, p. 129.) An engraving accompanies this paper, in which the hair and the beard appear as much developed as in the male sex.

In some cases, an external examination will entirely fail in indicating the sex, and even the opportunity of an examination of the dead body may leave the case in doubt. An ingenious writer has laid it down that there are analogous organs in the two sexes which are never found in the same subject, and the separate existence of which would enable us to determine the sex. These analogous parts are the penis and the clitoris—the scrotum and the labia—the testicles and the ovaries—the prostate gland and the uterus. This, however, is an artificial and, as facts show, an incorrect means of distinction. (See report of a case, in which a body resembling the prostate gland and a uterus existed in the same being, "Med. Times and Gaz.," Feb. 18, 1860, p. 177.) If a penis could always be clearly distinguished from a clitoris, and a scrotum from the labia, the rule might be serviceable; but it fails where it is most required, *i. e.*, in the mixed conditions. As to the other means of distinction, even if correct, they will only enable an examiner to form an opinion of sex in the dead, whereas it is during the *life* of one of these beings that the law requires the aid of medical science in the solution of these questions. The reader will find, in the "Med. Times and Gaz.," an account of some remarkable cases of sexual malformation by Mr. Curling (Jan. 24, 1852, p. 84); by Mr. Fletcher (Feb. 7, 1852, p. 136); by Mr. Broadhurst (Feb. 21, 1852, p. 187); and by Mr. Waters (May 21, 1853, p. 538). Other cases, reported by Mr. Mann and Mr. Churchill, will be found in the "Association Journal," 1853 (Aug. 19, p. 720, and Sept. 9, p. 799).

Mixed cases.—A case has been already mentioned in which neither testicles nor ovaries were found after death, and more than one instance has occurred in which both have been found—a case of intermixture of the sexes or real hermaphroditism, physically speaking, but of course without the functional power of self-impregnation. The following case is mentioned by Briand: The subject was about eighteen years of age when he died. The body was partly that of a male in configuration, and partly that of a female. An examination of the sexual organs, externally, led to no satisfactory distinction; and on inspection after death a testicle was found in what was supposed to be the left labium, with an

epididymis and a spermatic cord attached to it as usual; while on the other side were an ovary, Fallopian tube, and the rudiments of a uterus. The authenticity of this case was for some time a matter of dispute; but another, equally singular in its features, occurred to Prof. Mayer, of Bonn. This case clearly shows that such extraordinary deviations may be met with in nature. The person examined by Mayer died in 1835, at the age of 55. Different opinions had been formed during the lifetime of the being respecting the sex, by the first anatomists in Europe: some affirming that it was a male, while others contended that it was a female. This difference of opinion is sufficient to prove that *external* examination does not always enable even a good anatomist to pronounce an opinion on the probable sex of the being. In the dead body was found, on the right side, a withered testicle, with a penis and prostate gland, as male peculiarities; while on the left side was an ovary, with a uterus, vagina, and Fallopian tube. ("Med. Gaz.," vol. xix. p. 135.) It should be stated that the general configuration of the body in this case was that of a female; but there was duality of sex. The right half of the body was male, and the left half female.

But cases may present themselves in which there is really no sex; the person cannot be assigned either to the male or female variety. M. Tardieu has given a report of a case apparently of this kind, in the "Annales d'Hygiene" (1872, 2, 149). In these beings it is probable that there may be rudimentary organs of one or the other sex. This being was married as a woman at the age of 25. Her husband lived with her for more than two years before he took steps for a separation. It then turned out that the physical conformation of this person rendered a consummation of the marriage impossible. The wife was found to have no organs essential to the female sex. There were neither breasts, vagina, uterus, nor ovaries. The pelvis was more like that of the male than of the female, and although then 27 years of age, the being had not menstruated and had not suffered from any periodical lucular or abdominal pains. On the other hand, with the exception of the conformation of the pelvis and the absence of breasts, there was no male development. When, on the one hand, there is an absence of vagina and uterus, and on the other of penis and testicles, it may be fairly said that this being had no sex.

Causes.—The causes of malformation of the sexual organs, as of all other kinds of monstrosity, are involved in mystery. We know that in the early part of utero-gestation, the sex of a foetus cannot be distinguished; while, even when it has reached the fourth month, the genital organs are so similar that the sex can seldom be determined on inspection. Some organs or parts appear to be formed by equal and symmetrical portions, which gradually approximate and unite in the median line of the body. We observe this mode of union in the bones of the head, chest, and spine, as also in the various fissures (raphes) of the skin, which are the remains of a union between two equal and symmetrical parts of an organ, now become one. In regard to defects in organization, it may be remarked that they almost invariably occur in or about some part of the median line; and they appear to proceed from a mere arrest of growth or development of those particular parts, either on one side or both, during

the early stage of uterine existence. In this respect, the fissures sometimes observed in the palatine bones, in the palate itself, or in the lip—the openings occasionally noticed in the chest, diaphragm, anterior parietes of the bladder, as well as in the spinal canal, are precisely analogous in origin to the defective development of the sexual organs. There is nothing absolutely removed or lost, but there is an arrest of development; an opening, or fissure, which nature intended to be only temporary, becomes permanent by reason of an arrest of growth. In the evolution of the male genital organs, the part corresponding to the scrotum is at first always divided by a considerable fissure: and the penis and clitoris having, at this period of life, much the same kind of physical exterior, the sexual organs cannot be well defined. Should this fissure in the male not be afterwards filled up, then we shall have the most common variety of sexual malformation—the hermaphroditic form, with the male predominating. These observations are not, of course, applicable to those cases in which the sexes are positively mixed. In these instances there appears to be a separate sexual organization on the two sides of the body, with an imperfect development of each set of sexual organs. According to Weber, there is in the prostate gland a rudimentary uterus in every male. (“Baly and Kirke’s Recent Advances in Physiology,” 1848, p. 112. Also papers by Dr. Knox, “Med. Gaz.,” Nov. and Dec. 1843.)

One circumstance is worthy of note, namely, that sexual monstrosity appears occasionally to occur in the successive pregnancies of a well-formed female. The late Dr. Lever met with a singular instance of this in a female aged 28. She had given birth to four children in the three confinements, the first being a twin labor,—both the children males; and in both there was an arrest of development of the sexual organs. On the third delivery, the child was a male, and its sexual organs presented the same deformity as those of the twins. (“Med. Gaz.,” vol. xxxviii. p. 946.)

Medico-legal relations.—These beings, owing to defective development, are impotent and sterile. Questions connected with the legitimacy of offspring, divorce, and affiliation may, therefore, be raised with respect to them. Sexual monstrosity is not a ground for depriving a being of the rights of inheritance, except under peculiar legal conditions. Thus, a right of succession or inheritance to landed estate may depend upon the sex of the offspring—as where, for instance, two children are born, the first hermaphrodite, the second a well-formed male child. The parents die, and a title of nobility or lands may fall to the first-born male. Here the sex of the first-born must be determined before possession can be had. In a case of this kind, if medical evidence should establish that male peculiarities predominate in the first-born, the second child would be cut off. Again, if an estate were limited by entailment, as where it is settled upon heirs male and female of a particular family, the birth of an hermaphrodite, an only child, would create the legal necessity for a positive determination of the predominance of sex. So, if the hermaphrodite live but a few minutes after birth, and then die, the rights of persons may be subsequently much affected by the medical attendant having come to an opinion respecting its sex. Since we cannot determine under what

circumstances litigation may ensue, it is always right in a doubtful case to observe the sex, and make notes on the spot when a child thus malformed survives its birth but for a short period. The question of tenancy by courtesy, or the right of the husband to landed estate of which the wife was seized, will depend entirely upon the attention of the accoucheur to this point. (See "Tenancy by Courtesy," *ante*, page 672.)

When these beings have reached adult age, other questions may arise with respect to them. According to an old law of France, an hermaphrodite was permitted to choose one sex, and thereafter compelled to keep it! Hermaphrodites, or sexual monsters, were formerly ranked with infamous persons; and it has been a grave question in our courts, whether the calling a man an hermaphrodite was not such a libel or slander upon him as to render it a ground for a civil action. In a case reported by Chitty ("Med. Jour.," 374), the use of this term was held not to be actionable, unless it was proved that it had been attended with special damage. A dancing-master brought an action against a party for calling him an hermaphrodite, and it was decided that it was not sustainable: 1. Because such a union of the sexes cannot exist in fact, and every one must be supposed to know it; consequently the assertion could not be supposed to prejudice. 2. Because, admitting the possibility of such a double function, the party would be just as good, and perhaps even a safer dancing-master, than if only one perfect sex had been discoverable; consequently the words would not, in legal presumption, injure him in his profession or occupation!

I am indebted to a learned member of the bar for a note on the remarkable case of the *Chevalier d'Eon*. There was a great dispute concerning the sex of the Chevalier, and it came before a court of law on an action to recover a wager under the following circumstances (*Da Costa v. Jones*, "Cowper's Reports," vol. ii. p. 729). The plaintiff claimed of the defendant a sum of three hundred pounds. On the 4th of October, 1771, plaintiff paid to the defendant seventy-five guineas, on the condition that he, the plaintiff, should receive from the defendant a sum of three hundred pounds in case the Chevalier d'Eon should at any time prove to be a female. The cause was tried before Lord Mansfield, at Guildhall, and the jury found a verdict for the plaintiff, damages three hundred pounds, thereby affirming that the Chevalier was a *female*. A motion was subsequently made on behalf of the defendant to arrest the judgment, or at least to stay the proceedings, on the ground that the action could not be supported, as being upon a wager tending to introduce indecent evidence, and also as being one which materially affected the interests of a third person. The question thus raised on the motion was argued before the Court of King's Bench, and the judges unanimously agreed that the judgment must be arrested; the law not allowing wagers upon subjects leading to the introduction of indecent evidence (this being *contra bonos mores*), nor upon such subjects as are calculated to have an injurious effect upon the interests or character of a third person. Irrespective of this decision, the verdict was based upon what subsequently turned out to be untrue. The Chevalier was really a *male*, and not a female. He was carefully examined by Sir Anthony Carlisle, who satisfied all present

of the perfect condition of the testicles. (See *Paris and Fonblanque*, vol. i. p. 229.)¹

It would appear, from a singular case reported by Dr. Barry, that, in the United States, the rights of citizenship and the privilege of voting for members of Congress have depended on the determination of sex. In March, 1843, he was requested to examine the case of *Levi Suydam*, aged 23 years, a native of Salisbury, Conn. At the exciting and warmly contested election of the spring of that year, almost everything bearing the semblance of the human form, of the male sex, is stated to have been brought to the ballot-box. It was at this time, and under these circumstances, that the above-mentioned person was presented by the whigs to be made a freeman. He was challenged by the opposite party, on the ground that he was more a female than a male, and that, in his physical organization, he partook of both sexes. The following was the result of the *first* examination by Dr. Barry. There was a *mons veneris* covered with hair in the usual way; an imperforate penis, subject to erections, and about two inches and a half in length, with corresponding dimensions; the dorsum of the penis was connected by the cuticle and cellular membrane to the pubis, leaving about an inch and a half free, or not bound up, and towards the pubic region. This penis had a well-formed glans; a depression in the usual place of the meatus urinarius, with a well-defined prepuce and foramen. The scrotum was not fully developed, inasmuch as it was but half the usual size, and not pendulous. In the scrotum, and on the right side of the penis, there was one testicle of the size of a common filbert, with a spermatic cord attached. In the perineum, at the root of the corpora cavernosa, an opening existed through which micturition was performed; this opening was large enough to admit the introduction of an ordinary-sized catheter. Having found a penis and one testicle, though imperfectly developed, Dr. Barry, without further examination, gave it as his opinion, that the person in question was a *male citizen*, and consequently entitled to vote and enjoy all the privileges of a freeman!

On the morning of the first Monday in April (election day), Dr. Barry was informed that Dr. Ticknor would oppose Suydam's admission on medical grounds. Suydam came forward, and Dr. Ticknor objected

[¹ The CHEVALIER D'EON had served as a military officer, had acted as a diplomatist, and had fought duels, but his appearance was very effeminate; and after he had resided some years in England, frequenting race-courses and gaming-houses in male attire, Mr. Da Costa wagered a large sum with Mr. Jones that the supposed Chevalier was a woman, and brought the action mentioned in the text, which resulted as there stated. Lord Campbell, speaking of this case, says: "Although the verdict was set aside on legal grounds, it was allowed to settle many other bets which had been laid on the same question. The Annual Register for 1776, p. 167, says, 'By this decision, no less a sum than £75,000 will remain in this country, which would otherwise have been transmitted to Paris. The Chevalier has left England, declaring that she has no interest whatever in the policies opened on her sex.' The Chevalier, then assuming female attire, remained in France, supported by a pension from the French Government, for having long been a spy of Louis XV., until the breaking out of the Revolution in 1790. He then came to England, and, being in great distress, lived with a lady of reputation as her companion; but dying in the year 1810, was found on a post-mortem examination to be indeed of the sex which he had originally claimed, and in all respects perfectly formed."—Lives of the Chief Justices, vol. 2, 824 (Life of Lord Mansfield).—P.]

to him as a *female*, and therefore not entitled to vote. Dr. Barry then stated to the meeting, that, from an examination he had made, he considered the person in question to be a male, and requested that Dr. Ticknor might, with the consent of Suydam, retire into an adjoining room, and examine for himself. This was done, when Dr. Ticknor ultimately came to the conclusion that Suydam was a male. Suydam accordingly was admitted a freeman; and his vote was received and registered.

A few days after the election, Dr. Barry heard that Suydam had regularly menstruated. The sister of Suydam informed him that she had washed for him for years, and that he menstruated as regularly, but not so profusely, as most women. Suydam, when questioned, very unwillingly confessed that such was the fact. He was again examined by two physicians, when the following additional particulars were elicited: Said Suydam is five feet two inches in height, light-colored hair, fair complexion, with a beardless chin, and decidedly a sanguineous temperament, narrow shoulders and broad hips; in short, every way of a feminine figure. There were well-developed breasts with nipples and areolæ. On passing a female catheter into the opening through which micturition was performed, and through which, he again stated, he had a periodically bloody discharge monthly, instead of traversing a canal and drawing off urine, the catheter appeared to enter immediately a passage similar to the vagina, three or four inches in depth, and in which there was a considerable play of the instrument. He stated that he had amorous desires, and that, at such times, his inclination was for the male sex; his feminine propensities, such as a fondness for gay colors, for pieces of calico, comparing and placing them together, and an aversion for bodily labor, and an inability to perform the same, were remarked by many. Dr. Barry further learned from an old lady, who was present at the birth of Suydam, that on the second day after his birth, Dr. Delamater, who attended as accoucheur, made with an instrument the opening through which he had ever since performed micturition. ("American Journ. of the Med. Sciences," July, 1847.)

This was certainly an embarrassing case—one to which Lord Coke's rule for a decision, *i. e.*, the prevalence of either sex, is hardly applicable. The presence of a penis and one testicle referred the being to the male, while the boldly configuration, and still more strongly the periodical menstrual discharge, referred him to the female sex. The right of voting might have been fairly objected to, because, while the female characters were decided, the organs indicative of the male sex are described as having been imperfectly developed.

Dr. Hartshorne, an American physician, quotes a case in which an attempt was made by Dr. Gross, a surgeon in the United States, to destroy all sexuality, and thereby all rights of citizenship, in the case of an infant whose sexual organs were imperfect. (A report of this case will be found in the "American Journal of Med. Sci.," for Oct. 1852, and the "Ed. Monthly Journ.," for Jan. 1853.) The child, when seen by Dr. Gross, was three years of age, and had always, up to that period, been regarded as a girl, and in fact had been so pronounced at her birth by the accoucheur. At the age of two years she began to evince the taste, disposition, and feelings of the male sex; she rejected dolls and

similar articles of amusement, and became fond of boyish sports. She was well grown, perfectly healthy, and quite fleshy. Her hair was dark and long, the eyes black, and the whole expression most agreeable. A careful examination of the external genitals disclosed the following circumstances. There was neither a penis nor a vagina; but instead of the former there was a small clitoris, and instead of the latter a superficial depression or cul-de-sac covered with mucous membrane, and devoid of everything like an aperture or inlet. The urethra occupied the usual situation (in the female?) and appeared to be natural; the nymphæ were remarkably diminutive, but the labia were well developed, and contained each a well-formed testicle quite as large, and as firm as this organ generally is in boys at the same age. The hips, chest, thighs, and upper extremities were perfect. From this description it is pretty clear that the child was an *androgynus*, or there was imperfect development of the sexual organs, with predominance of those of the male. There was no indication of uterus or ovaries, nor any external peculiarity, except that which is frequently met with in hermaphrodites, in which there is an arrest of male development, but no intermixture of the sexes. Dr. Gross considered that for the child's future welfare and happiness, it would be better that it should have no testicles at all, than that it should retain them under such an imperfect development of the other organs. He therefore removed them by operation from the labia or divided scrotum, and had the dissatisfaction to find that they were perfectly formed in every respect, and that the spermatic cords were quite natural. The operation was performed in July, 1849, and three years subsequently (in 1852) it was found that emasculation was complete, for the disposition and habits of the being had materially changed, and were those of a girl; she was found to take great delight in sewing and housework, and she no longer indulged in riding sticks, and other boyish exercises.

The reasons assigned for the performance of this operation—namely, the entire deprivation of sex, and thereby of any sexual feelings in after-life—appear to me to be unsatisfactory. It is clear, from Dr. Gross's description, that this being was deprived of the rights and privileges of a *male* by the removal of the testicles. (See the case of *Levi Suydam*, *ante*, p. 717.) Dr. Gross appears to have contemplated the case only in a matrimonial point of view; but in a country where the rights of citizenship and power of voting for members of Congress are much valued, where they depend on direct proofs of sex, and are so strongly contested by opposing parties—it is a serious question whether he has not here struck a severe blow at the political rights of these beings, in thus wilfully destroying the physical evidence of the male sex! In this country, it might have been a question whether he had not rendered himself liable in damages for thus tampering with the laws of nature.

Concealed sex.—It is almost superfluous to say that in some cases sex cannot be determined by the dress, appearance, or even voice of the individual. Cases in which males have passed for many years unsuspectedly as females, and *vice versa*, have been numerous. In some instances the secret has been disclosed only by death. Facts of this kind belong rather to the annals of imposture than to those of medical jurisprudence.

A somewhat singular case of this description, that of *Eliza Edwards*, occurred to me in 1833. An unclaimed body was sent to Guy's Hospital, by the Inspector of anatomy, as a female. On removing the dress, however, it was found to be that of a *male*! From some suspicion respecting the cause of death, and the habits of this person, a coroner's inquest was held. It turned out that the deceased, whose age was twenty-four, had assumed the dress of a female at the age of fourteen, and had performed in many parts of England as an actress. The features had a somewhat feminine character; the hair was very long, and parted in the centre; the beard had been plucked out, and the remains of this under the chin had been concealed by a peculiar style of dress. It was remarked during life that the voice was hoarse. The breasts were like those of a male, and the male sexual organs were perfectly developed. They had evidently been subjected to great traction, and appeared to have been drawn forward to the lower part of the abdomen. The state of the rectum left no doubt of the abominable practices to which this individual had been addicted. It was found that death had taken place from natural causes. The most remarkable circumstance in the case is, that the deceased had been attended in his last illness by an eminent physician (now deceased) for disease of the lungs; and so well was the imposition maintained, that his medical attendant did not entertain a suspicion of the real sex of his patient! ("Med. and Phys. Jour.," Feb. 1833, p. 168.)

A more remarkable case, in which a female had successfully personated a male for many years, occurred in 1865. I refer to the case of *Dr. James Barry*, who was well known as Staff Assistant-Surgeon and Inspector of Hospitals. She died in 1865, at the age of 80; and although suspicions had existed among those who had personally known her, that she labored under some sexual defect, it was only proved after her death that she was really a woman. She is reported to have been the illegitimate child of a nobleman. When, where, and how she passed through her medical studies no one knows, but she contrived to obtain a diploma as Doctor of Medicine from Edinburgh when only fifteen years of age. The learned examiners of the Edinburgh College may at this time have been easily deceived respecting the sex of the candidate. The young physician entered the army, and served at the Cape of Good Hope, St. Helena, the Ionian Islands, Malta, and the West Indies. Although eccentric, she is said to have displayed on various occasions great professional skill. She was noted for being very quarrelsome, and on one occasion at the Cape she challenged and fought a duel with a brother officer. In due course she retired from the service, received a pension, and was made Inspector of Hospitals. In 1857-8, and subsequently, I saw Dr. Barry, and had the opportunity of observing her for several days. Her appearance and manners were effeminate. Her face and hands were smooth and white, like those of a woman; she had no beard or whiskers. She was irritable and vain; she was well informed and able to talk on most professional subjects in a manner which showed that she had studied them with care. Her habits were peculiar; she was a vegetarian in diet, and at dinner ate fruit or vegetables, which she first soaked thoroughly in water in order to remove, as she informed her

friends, the animalcula upon them. She was thin, and in stature resembled a woman, her limbs being small, but in good proportion. Her voice was shrill and squeaking, quite unlike that of a man. The impression left upon the mind of all those who saw her was that she labored under some sexual malformation. After her death, however, it was found that she had the sexual organs of a woman. She had specially desired that no post-mortem examination of her body should be made, but this order was disobeyed, a special report having been ordered by the authorities. It is difficult to comprehend how, in assuming the attributes and duties of an army medical officer, she could have so successfully maintained the deception through a long life. Whether she menstruated or not does not appear; although always accompanied by a black man as a valet, she was very secret with him, and would not allow him to be present while she was dressing. She is said to have always worn a peculiar and tight-fitting dress. Her military companions and associates may have rested content with the belief that she was laboring under some sexual defect; but the army Medical Board appears to have been easily deceived, as it did not hesitate to grant titles, privileges, and pensions to a woman wearing the attire of a man.

IMPOTENCY. STERILITY.

CHAPTER LVIII.

IMPOTENCY.—CAUSES.—PROCREATIVE POWER IN THE MALE.—PUBERTY.—AGE FOR VIRILITY.—VIRILITY OF CRYPTORCHIDES AND MONORCHIDES.—STERILITY.—PROCREATIVE POWER IN THE FEMALE.—EARLIEST AND LATEST PERIODS FOR CHILD-BEARING.—LEGAL RELATIONS.

Definition.—Impotency is defined to be an incapacity for sexual intercourse. It may depend—1st, upon *physical*, 2dly, upon *moral* causes. With regard to the *moral causes* of impotency, they do not concern a medical jurist; such causes are not recognized by law, and he has no duty to perform beyond the application of the principles of medicine to the purposes of the law.

Causes.—Impotency may arise from *age*—from certain *physical causes*, *e. g.*, disease—or from congenital malformation or *defect*. With regard to *physical causes*, a distinction must be made between those which are remediable and those which are not. The presence of a disease of the testicle, such as atrophy or fungous tumor, may give rise to incapacity; but this incapacity may be sometimes removed by an operation or by medical treatment, and therefore the physical causes may be removed: in other words, it is *remediable*. To such cases as these, the law does not extend; but it is always expected, in alleged incapacity, that the

practitioner examined on the subject should be able to say whether there is or is not a prospect of cure. In forming a judgment upon this point a good knowledge of his profession can alone assist him; no rules can be laid down for his guidance, for there may not be two cases that will precisely resemble each other in their features. Hence it will be necessary in this place to point out the chief causes of impotency which are of an irremediable nature, or those in which the incapacity is absolute and permanent,—a point upon which medical opinion is chiefly required.

In strictness of language, the definition of impotency as above given, may be applied to a *female* as well as to a male; and undoubtedly, a physical incapacity for sexual intercourse may exist in either sex. As an instance of this incapacity in the female, may be mentioned occlusion of the vagina—a condition not necessarily indicative of sterility. The mere occlusion of the vagina may be a remediable form of the malady; but its entire obliteration would be an absolute and irremediable defect. This latter condition, however, is the only instance of complete impotency in a female. A protrusion of the uterus or of the bladder into the vagina is mentioned by some writers as a cause of physical incapacity for intercourse; but these forms of disease may commonly be remedied by art, and therefore require no further notice in this place.

In professional language, the term *impotency* has been hitherto applied exclusively to a defect in the *male* sex; and the term *sterility* is usually confined to all those conditions in the female which not only render intercourse impossible, but which render it unfruitful. A male may, however, be sterile without being impotent—a condition observed in some cryptorchides; or he may be impotent without being sterile, as where proper intercourse is prevented by reason of physical defect in the virile member, although the testicles may be in a normal condition. See on this subject, Curling on “Sterility in Man” (1864). This author points out that sterility in the male, apart from impotency, may depend on three causes—1st, malformation of the testicles; 2dly, obstructions in the excretory ducts; and 3dly, impediments to the escape of the seminal fluid. A man may not be impotent, *i. e.*, incapable of intercourse, but, by reason of one of the conditions above mentioned, such intercourse would be unfruitful. In reference to the male, the English law does not appear to go beyond the establishment of impotency from some clear and demonstrable cause; and unless the alleged sterility were accompanied by impotency, it would take no cognizance of that condition. Further, sterility from such causes could hardly be demonstrated during the life of a person—it would rest chiefly on presumption or probability.

Procreative power in the male. Puberty.—Until the period of puberty the testicles are small, and they increase very little in size in proportion to other parts. Mr. Curling found that the size of the seminal tubes differed but little at the age of 18 months and 8 years. The sexual function in the male depends entirely on the development of the testicles; but the age at which it appears, differs in different persons. The age of puberty in a healthy male in this country varies from 14 to 17 years; its appearance is, however, affected by climate, constitution, and the moral circumstances under which the individual is placed: in some cases it is not fully developed until the age of 21.

The access of puberty in the male is indirectly connected with the subject of rape. A boy under the age of *fourteen years* is presumed in law to be incapable of committing a rape. (1 Hale, p. 631, and Mathew's "Digest," p. 57.) This presumption is entirely abolished under the new Criminal Code, and the age at which a male can be guilty of rape is left entirely open. The statute law merely requires proof of penetration, so that rape might be physically perpetrated by a boy at or even under 14 years of age. In several recent cases, boys at 14 have been convicted of rape. In a case elsewhere related (see RAPE), a boy aged 19 communicated syphilis to a girl of 6 years of age. It appears that in India puberty shows itself much earlier in the male. Dr. Cheevers, quoting from the "Nizamut Adawlut Reports," states that a boy of 13 or 14 years of age was found guilty of rape and sentenced, in consideration of his youth, to three years' imprisonment. A lad of 14 was convicted of rape on a girl of the same age; and in another case a boy only *ten years* old, was convicted of rape on a girl 3 years of age! He was sentenced to a year's imprisonment. (Med. Jur. for India," p. 463.)

The seminal secretion in the male is not considered to be prolific until it contains those peculiar filiform bodies which are known under the name of *spermatozoa* or zoosperms. These are regarded by some physiologists as parasitic animals, but by others, with some probability, as free moving cilia. ("Recent Advances," Baly and Kirkes, 1848.) All agree that they are normal and essential constituents of the healthy and prolific seminal fluid. They are peculiar to the spermatic secretion, and in healthy males, are always present in it after the age of puberty. They disappear in certain states of disease, and sometimes in advanced age: they have not been found in the undeveloped testicles of cryptorchides. In cases in which they are absent, from whatever cause, it is a fair inference that the person is impotent, or that he has lost the power of procreation. (See on this subject "Observations on Sterility in Man," by T. B. Curling, 1864.) In this pamphlet one case is related in which a man, aged 42, who was married, and whose wife had born a son then eight years of age, had died after four days' illness from strangulated hernia. The testicles, from the fact of their being found in the original canal, were examined separately by Drs. Gosselin and Godard, and no spermatozoa were discovered in the fluid contained in either of them; but these may have been merely absent at the time of examination, as the child begotten was then eight years of age. During this long interval, the secretion may have undergone a change, and have become unprolific.

The presence of spermatozoa in the seminal secretion is indispensable to the impregnation of a female—in fact, the fecundating power resides in these living and moving molecules. It is a curious fact, too, that active motion in the spermatozoon is essential to fecundation; thus, when they are motionless, ova are not impregnated by them, and the power of impregnation is in proportion to the activity of this motion. The impotence arising from advanced age in the human subject, is probably not so much owing to a deficiency of spermatozoa in the male secretion, as to their power of motion being exceedingly feeble. We learn, further, that impregnation is more certain when the quantity of

spermatozoa supplied to the ovum is not reduced to a minimum ; hence, whatever may be the precise quantity of the spermatic secretion necessary to effect normal impregnation, it is proved that a definite quantity of spermatozoa, or of healthy spermatic fluid, is required to fecundate.

Impotency from age.—It may be fairly assumed that a male is incapable of procreating until spermatozoa have appeared in the seminal secretion, and that he loses this power when they disappear. The age at which they are formed, varies with all the causes that affect puberty. In one instance they were found by Casper in the seminal fluid of a cryptorchid boy only 14½ years old, and Mr. Curling found them in the secretion of a boy aged 18. This gentleman found spermatozoa in the liquid taken from the testicles of a man upwards of 70 years of age; and on one occasion in the testicles of a person aged 87. Wagner states that they are to be found in the secretions of men between 70 and 80 years of age. M. Rayer found them in the secretion of a man aged 82 years. ("Gaz. Méd.," June 2, 1849.) Other cases of a similar kind are recorded by Debrou. ("Gaz. Hebdom.," 4th Janvier, 1861, p. 6.) Mr. Dien, of the Invalides, examined the bodies of 106 men between the ages of 64 and 97. In 64 cases out of the 106, there were no spermatozoa, *i. e.*, in 61 per cent. Four of Mr. Dien's observations were on nonagenarians; of these none had spermatozoa. ("Med. Chir. Rev.," June, 1868.) Facts tend to render it highly probable that a fecundating power may be retained by the male up to the age of 100. According to Dr. Duplay, the seminal fluid of old men contains spermatozoa even when they are beyond the age of fecundation ("Med. Times and Gaz.," June 4, 1853, p. 581); but he does not state the circumstances which enabled him to arrive at this conclusion. Sexual propensities are often strongly developed in children, and thus they may be prolific at an early age. Dr. Rüttel met with a case in which a female, at the age of 14, became pregnant by a boy of the same age. (Henke's "Zeitschrift der S. A.," 1844, p. 249.) This is the earliest age at which, so far as I can ascertain, the procreative power has appeared in the male. Dr. Hartshorne refers to an instance of extraordinary development of the male sexual organs in a child 4 years old. ("Amer. Jour. Med. Sci.," Oct. 1852, p. 561.) In a case of contested legitimacy or affiliation, this question regarding the age at which a procreative power appears in the male, may have an important bearing on the issue. Thus the person may be so *young* as to render it impossible that he should be the father of a child imputed to him. Cases involving questions of legitimacy on this ground are not heard of in the present day: but in ancient law-books there are decisions relative to the illegitimacy of children born during marriage, because the alleged fathers were 7, 6, and even 3 years old! (Amos.)

The following case in reference to the affiliation of children occurred in 1840: A woman wished to affiliate a child on a youth who was in his *sixteenth* year. The boy denied that he was the father of the child; and there was reason to suspect that the imputation had been wrongly thrown upon him in order to divert suspicion from the real offender. There was some difficulty in this case; but it appears to me that the rule for a medical man to follow on these occasions is this: not to regard the mere age of the youth, whether he is above or below the average age of puberty,

but to observe whether the sexual organs are fully developed, and whether there are about him any of the marks of precocious virility, indicated by muscular development, the growth of a beard, and a change in the voice. If these signs are present, whatever may be his age, there is strong reason to suppose that the sexual functions are developed. We occasionally hear of instances of extraordinary precocity; but the development of sexual power is generally accompanied by other well-marked changes in the person. Sometimes these changes do not make their appearance until after the age of 21.

On the other hand, it may be a question at what time the procreative power disappears in a male. That impotency is one of the natural consequences of *advanced age* is undoubted; but this, as we know, forms no legal impediment to the marriage of parties, however old. The legal presumption is, that the generative faculty does not disappear through age; and if this be alleged, and legitimacy disputed on this ground, it must be satisfactorily proved by those who would benefit by the allegation. This amounts to almost an impossibility, because it is well known that there is no fixed age at which the sexual functions cease either in the male or female; and individuals at least of the male sex, who had passed the ages of 60, 70, and even 80 years, have been known to be capable of fruitful intercourse. M. Duplay believes, from his anatomical observations on the bodies of aged persons, that the causes of impotency (sterility) in advanced age, are to be found rather in the excretory than in the secretory apparatus. Thus he has met with obliterations in the canal of the epididymis, the vas deferens, and the vesiculæ, the effect of which is to prevent the accumulation and passage of the seminal fluid. ("Med. Times and Gaz.," June 28, 1856, p. 650.) Lord Erskine, in the *Banbury Peerage* claim, quoted the case of Sir Stephen Fox, who was married at 77, and had had four children, the last when he was 81. Dr. Schneider met with a case in which a man of 71 had a child by his wife, who was only 17. (Henke's "Zeitschrift," 1842, vol. 2, p. 165.) Dr. Rüttel mentions the case of a man who, at the age of 92 years, married and had two children by his wife. When the procreative power even appears to be lost at an advanced age, the stimulus for intercourse is often very great. The same authority mentions cases in which these erotic feelings were remarked by him in reference to men between 75 and 86 years of age. (Henke's "Zeitschrift," 1844, p. 252.) In all cases of prolonged virility, it is observed that the bodily and mental powers are also retained in an extraordinary degree, showing the close relation which exists between the sexual function and corporeal and mental development, even to the latest period of life. Sir S. Romilly remarked, in reference to the retention of procreative power in advanced age, that the liberality of the English law on this subject was excessive; for there was no age, from *seven* upwards, at which a man had been denied the power of procreating children! (See, in reference to this subject, Henke's "Zeitschrift der S. A.," 1842, p. 332.) Males at the age of 14, and females at the age of 12, are legally competent to contract marriage.

Impotency from local disease or accident.—The loss or destruction of the penis or testicles, either by disease, accident, or from necessary ope-

rations, would be sufficient to render a man irremediably impotent. The loss of one or both testicles, from any of these causes, would be indicated by the presence of distinct cicatrices in the scrotum. When both have been removed by operation, the person is incurably impotent; but if the organs are healthy, a sufficiency of the spermatic fluid to confer procreative powers may remain in the ducts for two or three weeks after the operation. Thus it is that animals have been known to be prolific for a certain time after castration; and one case is on record, in which a man, both of whose testicles had been carried off by a gunshot, is said to have retained the power of impregnating his wife after the healing of the wound. (See a paper by Dr. Krügelstein, Henke's "Zeitschrift," 1842, vol. 1, pp. 348 and 352.) The loss of *one* testicle only, by accident or operation, does not render a man impotent. *Monorchides*, as they are called, have been known to be prolific. Cases of this kind must not be confounded with those in which one or both testicles have not descended into the scrotum.

In some rare instances the testicles do not descend into the scrotum at the usual period: but one or both may remain either in the abdomen or in the inguinal canals, and only descend some time after birth; or one may be found in the scrotum, and the other remain during life in the abdomen. In some cases of partial descent, the organs have been mistaken for, and treated as, ruptures by the application of a truss! (Henke's "Zeitschrift der S. A.," 1844, vol. 1, p. 249; Curling on "Disease of the Testis," 2d ed. p. 31.) In one instance the attempt to reduce the tumor, mistaken for hernia, and the application of a truss, caused the death of the person. ("Med. Times and Gaz.," March 2, 1861, p. 240.) When one testicle only has descended, there is no ground, *cæteris paribus*, to impute impotency: the descended organ has been found healthy and to contain spermatozoa. Mr. Curling has collected six cases in which the retained testicle and its ducts did not contain spermatozoa; four of these fell under his own observations. ("On Sterility in Man," 1846, p. 6, and "Med. Times and Gaz.," Feb. 23, 1861. When neither testicle has descended, the scrotum will be found empty, without any scar indicative of a removal by operation, but the other marks of virility may still be present. These persons have been called *Crypsorchides*. It has been stated that in such cases the testicles are to be regarded as congenitally defective, and further that the individual, although capable of sexual intercourse, is incurably sterile.

The non-descent of the testicles is a state rarely seen. Mr. Marshall met with only one case of non-descent of one testicle in 1000 recruits, and with one case of non-descent of both testicles in 10,000 recruits. There are three preparations, showing the non-descent of the organs, in the Museum of Guy's Hospital; one of them was taken from a gentleman who shot himself from despondency at his supposed defective condition. Hunter thought that the undescended testicles were always imperfect both in their structure and functions, and that crypsorchides were invariably impotent (sterile). Some recent researches have tended to support the views of Hunter. In January, 1860, the late Mr. Partridge communicated to the Pathological Society the case of a man of 25, in whom both testicles were found in the abdomen. Several specimens of

the secretion from the organs were examined, and no spermatozoa were detected. Another case was examined with a like result ("Lancet," January, 1860, p. 66), and a third by Mr. Curling ("Med. Times and Gaz.," February 23, 1861). The conclusion to which these observations have led is, that although in cases of non-descent there may be a capacity of sexual intercourse, it would not be prolific: the person will be sterile. According to this view malposition of the organs must be taken as synonymous with defective condition: as a result of this malposition they are not capable of secreting prolific spermatic fluid, and the person is as sterile as if he had no testicles. The case of monorchides reported by Mr. Curling (*op. cit.*, p. 8) to some extent support this theory, since spermatozoa were found only in the fluid of that testicle which occupied its usual position in the scrotum. He has also collected from various sources seven cases of cryptorchides, in which both testicles were either in the abdomen or in the inguinal canals; the fluid contained in them was destitute of spermatozoa, and although impotency did not exist, these persons either were or were presumed to be unprolific. M. Godard has noticed that horses whose testicles are retained in the abdomen, although capable of intercourse, are sterile.

On the other side of the question there are, however, facts which are wholly inconsistent with this theory. Many years since I published the account of two cases of cryptorchides communicated to me by my friend and colleague, Mr. Cock. The testicles in these men had not descended, but their virile functions were undisputed. One of them, before he had reached the age of 30 years, had been twice married, and had had children by each wife, besides illegitimate children which were affiliated on him during the time he lived in service. In a report of cases of hernia by the late Mr. Poland ("Guy's Hospital Reports," 1843, vol. 1, p. 163), there is the case of a man, aged 29, a cryptorchid, whose testicles had not descended. Mr. Poland states that there was not the slightest trace of scrotum; the penis was well-developed, and there were all the other signs of virility. This man had married when he was twenty: he had had two children by his first wife, and at the time of his admission into the hospital, had been married two years to a second wife. In January, 1862, I saw, in Guy's Hospital, a patient under Mr. Durham: the testicles of this man had not descended—they were lodged in the inguinal canals. The man was 32 years of age, well developed, with every appearance of virility about him, and with the same masculine development which is seen in other men of the same age. This man was married, and had had two children by his wife. Since puberty he had always been competent, and he ridiculed the idea that his testicles were inefficient. Another case is referred to by Mr. Curling (*op. cit.*, p. 9), which occurred to Dr. Debrou, of Orleans. The man had been married, and had had one son by his wife. These facts prove that cryptorchides, in some cases, have a power of procreation like normally constituted men. Casper relates a case in which a cryptorchid was charged with an unnatural offence. He was a boy between 14 and 15 years of age, and it appeared that he had been guilty of unnatural conduct towards another boy 8 years of age. Spermatozoa were detected by Casper on his shirt sixteen days after the act. On exa min-

ing the boy, both testicles were found in the inguinal canals. ("Ger. Med.," vol. 2, p. 187.)

By these facts, therefore, it is satisfactorily established that *cryptorchides* are not necessarily sterile, and that no absolute rule can be laid down respecting the existence or non-existence of prolific power under such circumstances. It has been objected that in the above instances of prolific power, spermatozoa had not been demonstrated to exist in the spermatic secretions of the individuals, and that the evidence was therefore incomplete. But these bodies were not proved to be absent, and most persons will agree that there is no better evidence of prolific power than the procreation of children, whether spermatozoa are or are not detected—a matter which will sometimes depend on the accuracy of observation or experience of the examiners, or, it may be, on a morbid state of the secretion. If none were found under these circumstances, it would prove only that our present theories of generation would require to be modified. One affirmative instance is sufficient for all the purposes of law, to overthrow ninety-nine negative instances; and as a physiological fact, it is obvious that the organs which have not descended, are not always defective in structure or function. The cases hitherto observed are so nearly balanced that it is difficult to say whether it is the rule or the exception that cryptorchides should be found prolific: the facts above mentioned clearly prove that there is no reasonable ground for pronouncing them to be absolutely sterile or unprolific, merely because their testicles are not in the scrotum. If with a non-descent of these organs there should be a non-development of the other external organs, and this is accompanied by a total want of the characters of virility, then the person may be regarded as impotent or sterile. The testicles may, in such a case, be either congenitally absent or physically imperfect—a fact only ascertainable by an examination of the body after death. On the other hand, in cases in which there are no external marks of effeminacy, or other grounds for suspecting a want of procreative power, and the person is capable of sexual intercourse, this imperfection does not offer any bar to marriage, nor is it sufficient ground for divorce. It would not justify a medical man in denying the paternity of a child on a question of affiliation, bastardy, or inheritance; and so long as a power of sexual intercourse existed, it would not justify him in pronouncing a person to be incurably sterile. The capacity for sexual intercourse is the fact to which the English law commonly looks on these occasions. If this exists, then it will hardly entertain the question—surrounded as it may be with conflicting medical opinions,—whether, from the mere retention of the organs in the abdomen, the fluid secreted is or is not, microscopically speaking, of a prolific nature? Women may be sterile from a variety of causes affecting the internal organs, only ascertainable after death. The ovaries may be so diseased that no prolific intercourse can take place, although there may be no physical incapacity. In a case related elsewhere, the incapability of *conception* on the part of a woman was held by Dr. Lushington not to be a sufficient ground for pronouncing a sentence of nullity of marriage (p. 739, *post*); and doubtless a want of power on the part of a man to effect impregnation, unless it depended on some visible physical defect, would be viewed in a similar

light. Such persons are not impotent but sterile, and sterility in an irremediable form, is rather assumed than demonstrated to exist.

The presence of what have been called supernumerary testicles does not affect the virile powers of a person. These have in general been found, by dissection, to be tumors connected with the healthy glands, and not at all adding to or interfering with their functions. Even the presence of two or three penes, according to Mende, is no bar to the exercise of sexual power, provided only one possesses the normal characters of the male organ. ("Ausführ. Handb. d. ger. Med.," vol. 4, p. 337.) In the summer of 1865, a Portuguese youth, aged 19, I. B. dos Santos, was seen by many medical men in London. He was well formed, except in reference to the sexual organs. He had two complete and well-formed penes, placed side by side: the right somewhat smaller than the left, and both subject to erection at the same time. He stated that he used the left in sexual intercourse. On the outside of each penis was a scrotum, with one testicle fully developed. Between them was a shrunken scrotum, which contained two testicles until he was 10 years old, when they ascended into the abdomen. When the bladder acted, urine issued from both penes. An engraving of this remarkable malformation is given with the history of the case in the "Lancet" of July 29, 1865, p. 124.

In some instances there is an arrest of development in the external organs: and with this there is generally an absence of sexual desire. Certain diseases of the appendages of the testicles may, however, render a person sterile. The spermatic secretion is commonly suspended in most severe diseases which affect the body. A frequent cause of impotency (sterility) in the adult, when the organs are apparently sound, is spermatorrhœa, arising from abuse or excess. This, however, is remediable to a greater or less extent by treatment. (See Curling, "Diseases of the Testis," 2d ed., p. 386; also "Med. Times and Gaz.," Jan. 23, 1858, p. 95.) The incapacity for intercourse in either sex may arise from *extensive disease* affecting parts in and around the organs of generation. The medical opinion here must be regulated entirely by the circumstances attending each case.

On the absence of the penis, as well as on its defective organizations, as causes of incapacity, some remarks have already been made. Sometimes the defect is merely connected with the urethra. Thus the orifice may be on the dorsum penis, and in other cases underneath the organ, so that the urethra may terminate at a variable distance from the glans penis. Those laboring under the former defect are said to have *epispadia*, and under the latter, *hypospadia*. Dr. Rose describes a case of *hypospadia* in a child who had been baptized, brought up and educated as a female at a girls' school. The androgynous child was ten years old, diminutive in size, and possessing girlish features. A testicle was recognized on each side, but no distinct penis. ("Obstet. Trans.," 1876, vol. 18, p. 256.) These beings are often mistaken for girls, but the absence of the function of menstruation is sufficient to remove doubt.

The power to have fruitful intercourse will in either case depend on the situation of the urethral aperture. Some doubt has existed respecting the virile powers of those who are afflicted with *hypospadia*; but

Rüttel knew an instance of an hypospadian having several children. (Henke's "Zeitschrift," 1844, p. 258.) In September, 1850, a lad, aged 17, was summoned before the magistrates of Kidderminster, on a charge of affiliation, in reference to the pregnancy of a girl aged 18. The defence was that he could not be the father of a child, because there was such a malformation of the penis as to prevent prolific intercourse. On examination, the urethra was found to terminate on the under surface of the penis, about an inch and a half from the glans, by a small elliptical orifice, which allowed the urine to pass, but with some difficulty. One medical witness gave it as his opinion that it was not impossible, but highly improbable, that the defendant should possess procreative power; another freely admitted the boy's capacity, and the case was decided against him. ("Med. Times," Sept. 21, 1850, p. 321.) This decision was physiologically correct. When the urine can pass the seminal fluid can pass; and the only question is, whether the intromission can be such as that the misplaced orifice should come in contact with any part of the vagina, or even the vulva? This must depend on the situation of the orifice. [Cases illustrative of the prolific powers of hypospadians will be found in the "Med. Times," Sept. 14, 1850, p. 292, and Oct. 12, 1850, p. 392. An instance of the virility of an hypospadian has also been published by Mr. Noble, of Manchester, in the "Assoc. Med. Jour.," March, 1853, p. 236.] Similar remarks apply to epispadians. These malformations are sometimes remediable: but whether remediable or not, they are not, under any circumstances, to be regarded as absolute causes of impotency.

Impotency from general disease.—The influence of local disease in affecting virility has been already considered. But there is a class of cases which may come before a practitioner, in which, with well-formed and healthy organs in the male, there will be a state of impotency, or incapacity for intercourse. Sometimes this may depend on natural weakness of constitution, or on a want of proper development of the muscular and nervous systems: at other times it may be due to certain diseases, and it is then of a temporary nature—persisting while the body is still suffering from the disease, and disappearing on recovery. As a converse fact, there are some diseases which appear to bring out the dormant virile powers of persons, or to excite to a higher degree of intensity those which already exist. Thus it is said that in convalescence from fever there is, occasionally, extraordinary salaciousness: but this statement requires confirmation. Again, there are diseases which neither interrupt nor affect the exercise of the sexual functions. As a general rule, diseases which do not affect the brain or spinal marrow, and which are not attended with great bodily debility, do not prevent fruitful intercourse. On the other hand, diseases which are attended or followed by great debility or cerebral exhaustion suspend or destroy sexual power. Among these may be mentioned water in the chest, general dropsy, especially if attended with effusion in the sexual organs,—nervous and malignant fevers which affect the brain,—apoplexy, palsy, and other diseases which directly attack the brain or spinal marrow. These last-mentioned diseases probably act by suspending the secretion, or altering the nature of the prolific fluid, as well as by preventing that erection of the male organ without

which intercourse cannot take place. The sexual function is so intimately allied to bodily vigor and nervous energy, that the integrity of the one may be pronounced to be essential to the integrity of the other. Habits of drunkenness and the abuse of alcoholic liquids, tobacco, or opium, may give rise to impotency by the injury done to the brain and nervous system. (The reader will find this subject fully discussed by Mende, "Ausführ. Handb. der ger. Med.," vol. 4, p. 349.)

In *Wood v. Hotham*, Jan. 7, 1864, the defendant, a surgeon, was sued for a sum of money for his wife's maintenance. He alleged, in defence, that his wife had been guilty of adultery, and that one of two children born during the marriage was not his. He assigned as a reason for this, that he was so ill at the time that it was impossible he could have had connection with his wife. It appeared, however, that he was then in the habit of sleeping with her, and he was sufficiently strong to go his round of daily visits. The learned judge, in remarking upon this point, said if such evidence were to be held sufficient proof of illegitimacy, the whole of the law relating to the access and non-access of a husband must be set aside. The jury returned a verdict for the plaintiff. [See the case of *Page v. Dennison*, 5 Casey, 420, cited *ante*.—P.]

Diseases and injuries of the spinal cord, producing paraplegia have no direct effect on the testicles, but destroy the power to copulate. (Curling, *op. cit.*, p. 371.) When there is a wasting of the testicles, as a result of general paralysis of long standing, there can be no doubt of impotency; but Mr. Curling quotes a case from a foreign writer in which, under paralysis (paraplegia) of some years' duration, a man retained sufficient sexual power to have prolific intercourse. When the paralytic person is advanced in age, it is highly probable that he is impotent. In December, 1857, a case was referred to me, in a question of bastardy, for my opinion on a capacity for intercourse, under the following circumstances. A woman required an order of affiliation on the putative father of her bastard child. She was a widow, and the illicit connection took place about two months before her husband's death. The husband was at the time 84 years of age; he was bedridden, and for many weeks before his death he could not move in his bed, and was unable to pass his urine without assistance. The medical opinion of those who examined him was that he was impotent from physical infirmity, and in this opinion I concurred: stating, however, that unless the male organs were diseased or destroyed, it could not be said that intercourse was impossible. It was, however, wholly improbable that the husband could have been the father of the child.

Blows on the head or spine, by affecting the brain and spinal marrow, may produce impotency. Several cases of impotency from this cause are related by Curling (*op. cit.*, p. 362). It has been noticed that blows on the under and back part of the head, in the region of the cerebellum, have been followed by loss of sexual power on recovery. Sometimes this is temporary; but at other times, when there is wasting of the testicles, it is permanent and irremediable.

Of *moral* causes it is unnecessary to speak. The sexual desire, like other animal passions, is subject to great variation; and there are instances on record in which men, otherwise healthy looking, and healthily

formed, have experienced no desire of this kind. They are in a state of natural impotency—a condition which the Canon Law designates as frigidity of constitution. This is not to be discovered by external examination, but rather from their own admission. Under this head we may class some hypochondriacal affections.

Sterility. Definition.—Sterility is usually defined to be “the inability to procreate, or a want of aptitude in the female for impregnation.” It is not usual to speak of sterility in the male, although there may be procreative incapacity; because the defective condition in this sex, from whatever cause, is, in a legal point of view, included under the term “impotency” (see p. 722, *ante*). In the strictness of language, a male who has been castrated is sterile; but it is commonly said that he is impotent. Many apparently well-formed males may be sterile without being impotent, *i. e.*, they may have intercourse without procreating; for the power of copulating must not be confounded with that of procreation. Mr. Curling has pointed out that various causes may render a male sterile, although he may retain a power of sexual intercourse, and thus cannot be regarded as impotent in a legal sense. (“Diseases of the Testis,” ed. 2, p. 216.) Some crypsorchides may be sterile or deficient in procreating power, while at the same time impotency or incapacity for intercourse may not exist. In reference to women, sterility implies that condition in which there is an “inability to conceive.” This appears to be the true meaning of the term, and the sense in which it is used not only by the best writers but in common phraseology.

Procreative power in the female. Puberty.—In the *female*, the procreative power is supposed not to exist until after the commencement of menstruation, and to cease upon the cessation of this periodical secretion. The menstrual function is commonly established in females in this climate between the ages of *fourteen* and *sixteen*; but it may occur much earlier—indeed, in some rare instances, a discharge resembling the menstrual has been known to occur in mere infants. (“Lancet,” 1871, vol. 1, p. 366.) In other cases, its appearance has been protracted to a much later period. Dr. Cohnstein states that the average duration of this function among women in 400 observed cases, was 31 years. (“Brit. Med. Jour.,” May, 1873.) According to Dr. Rüttel, the menstrual function appears in the smallest number of females at 12, 13, and 14, and in the largest number at 16, 17, and 18 years. In some it is only first established at from 19 to 21 years; and he states that at this age he has often found the uterus small and quite undeveloped. The earliest and latest periods in a large number of cases were respectively 9 and 23 years. (“Lancet,” Nov. 30, 1844, p. 283.) Perhaps in this country, the most frequent age for the commencement of menstruation may be taken at 15 years. It is liable to be accelerated in its appearance by certain moral and physical conditions under which a girl may be placed. The most common intervals for its appearance are twenty-eight and twenty-one days. It sometimes does not appear till late in life. Dr. Camps found that it had not appeared in a married woman, *æt.* 30, who had borne no children. (“Med. Gaz.,” vol. 32, p. 409.) Another case is mentioned in the same volume, where it appeared for the first time at the age of 47

(p. 567.) So soon as this function commences, a woman may be considered to have acquired procreative power; but a female may conceive before the function has commenced, during the time of its occurrence, or even after it has ceased. From facts elsewhere stated, there is some reason to believe that the period which immediately precedes or follows the discharge is most favorable to conception; although the experience of many accoucheurs has shown that impregnation may take place at any time between one menstruation and another (p. 685, *ante*.)

It is important to remember that these changes in the uterus may produce remarkable effects by sympathy with the brain and nervous system. At or about the time of puberty, especially if any cause of obstruction exists, some girls are observed to become irritable, easily excited, and they have been known to perpetrate, without motive, crimes of great enormity, such as murder and arson. A propensity to steal is also stated to manifest itself in some cases. (See *post*, KLEPTOMANIA.) It has been remarked that acts of arson and murder have been frequently committed by girls at this period of life without any apparent motive or for the most trivial reasons, and the crime has spread by imitation. The case of *Brixey*, tried for the murder of an infant, and acquitted on the ground of insanity, will serve as an illustration of the morbid effect produced on the brain by disordered menstruation. (See *post*, INSANITY.) Other cases have been already referred to in this work in which crimes of the greatest magnitude have been traced to girls of this age, but without any apparent ground for imputing actual insanity. The only suggestion that could be advanced in favor of insanity was the atrocity of the act without any of the ordinary motives which actuate criminals, and the fact that the acts of murder have been perpetrated on helpless children incapable of giving offence. In the case of *Vamplew* (Lincoln Aut. Ass., 1862) it was proved that the prisoner, a girl under 13 years of age, acting as nurse in a family, had destroyed with strychnia an infant entrusted to her care. It transpired that in two other families she had previously destroyed with poison infants placed under her charge. The case of *Constance Kent*, a girl between 15 and 16 years of age, furnishes another illustration. She was convicted on her own confession of the murder of her infant step-brother, under circumstances showing great atrocity and cunning, and for which no motive could at the time be suggested. Lastly, there is the case of the girl *Norman* (p. 486, *ante*), aged 15 years, convicted of an attempt to murder, by suffocation, a child placed under her care as nurse. It came out that four other children to whom she had been nurse had died under her hands from suffocation! There was no evidence of intellectual insanity in any of these cases, nor was there anything to show that the uterine sympathy, if it existed, was beyond the power of self-control. They were all convicted of the crime of murder. At this period of life, the state of the mind should be closely watched, and any causes of irritation or violent excitement removed. Irregularity, difficulty, or suppression of the menstrual secretion, may give rise to temporary insanity, indicated by taciturnity, melancholia, capricious temper, and other symptoms. Puberty in the *male* may be attended with similar morbid propensities, but these are not so commonly witnessed as in the female.

Pregnancy before menstruation.—The previous occurrence of menstruation is not indispensable to pregnancy; many cases are on record in which women who have never menstruated have conceived and borne children (p. 541, *ante*). One case is reported in which a woman, aged 25, became pregnant and bore a child, and menstruation was only regularly established afterwards. (“Lancet,” February, 1842.) Dr. Murphy mentions another instance of pregnancy previous to menstruation in a woman aged 23. (“Obstetric Reports,” 1844, p. 7.) Numerous cases of conception without previous menstruation, are quoted by Capuron (“Mém. Lég. des Acc.,” p. 96); and no fewer than nine instances of pregnancy before menstruation have been collected by Mr. Whitehead. The women were all in excellent health during the whole time, and one did not menstruate until more than two years after the marriage had been consummated. (“On Abortion,” p. 223; see also Orfila, “Méd. Lég.,” 1848, vol. 1, p. 257.) Another case will be found reported in the “Medical Gazette” (vol. 44, p. 969). Dr. W. Taylor met with an instance in which a girl, aged 13, bore a child before menstruation had appeared. (“Med. Times and Gazette,” March 12, 1853, p. 277; see also, for remarks on this subject, “Edin. Monthly Jour.,” July, 1850, p. 73.) The late Dr. Reid has reported a case in which a patient of his bore a child at the age of 17, without having previously menstruated; he also collected from various authorities other cases of pregnancy occurring in women who had not menstruated. (“Lancet,” September 3, 1853, p. 296.)

[At a meeting of the College of Physicians of Philadelphia (Sept. 4, 1861), Dr. R. P. Thomas stated that he had lately, for the third time, attended in confinement a lady who had been married about twelve years, and had given birth to six healthy children, although she had never menstruated. She was married at 22, and had always enjoyed good health; her labors were natural, with but little show and no subsequent lochial discharge. Dr. Hays, on the same occasion, mentioned the case of a lady patient of his, who had menstruated very rarely, not oftener than once a year, and yet had borne six healthy children at intervals of fourteen months, and was a healthy woman.—H.]

Instances of *premature puberty* in the female sex are now numerous; they are far more common than in the male sex. Mr. Whitmore met with the case of a female child who, from a *few days* after birth, menstruated regularly, at the periods of three weeks and two or three days, until she had attained the age of 4 years, when she died. On inspection after death, she appeared like a much older girl. The breasts were unusually large, and the female organs and lower limbs were considerably developed. (“Northern Jour. Med.,” July, 1845, p. 70.) Another case is reported in the “Lancet” (January 29, 1848, p. 137); this was a child aged 3 years. The breasts were as healthily developed as in an adult of twenty years, and the sexual organs were also as much developed as in a girl at the age of puberty. It was observed that this child, who had been regularly menstruating for twelve months, had the appearance of a little old woman. (For other cases of menstruation at 5 years, see “Med. Gaz.,” vol. 25, p. 548; at 3 years, vol. 47, p. 244; and at 3½ years, “Med. Times and Gaz.,” July 24, 1858, and “Brit. Med.

Journal," Dec. 1873, p. 666.) More recent cases are recorded. One, a girl, æt. 2, in good health, regularly menstruated in a natural way. Another, æt. 8, also performed the function in the usual way. ("Brit. Med. Jour.," Oct. 1875, p. 514.)

In these instances of early menstruation, there is great reason to believe that a procreative power is also early developed: but it is not common to hear of such young females becoming impregnated. A case is mentioned by Dr. Beck, in which a girl menstruated at one year; she became pregnant, and was delivered of a child when little more than *ten years* old. Dr. Walker met with a case in which the menstrual function was established at the age of $11\frac{1}{2}$ years, and the girl was delivered of a living child when only twelve years and eight months old. ("Amer. Jour. Med. Sci.," October, 1846, p. 547.) In another observed by Rüttel, already referred to, a girl of the age of *fourteen*, became pregnant by a boy of the same age. He also quotes three other cases, where one girl at the age of *nine*, and two at the age of *thirteen*, became pregnant (*loc. cit.*) The first of these three cases represents the earliest age for pregnancy yet assigned by any author. In a case of a criminal assault on a girl under 12, tried at the Maidstone Winter Assizes 1878-9 (*Reg. v. Dean*), it was proved in evidence that a girl of the age of 12 years and one month had been delivered of a full-grown child, which was then living. The prisoner, who was the girl's stepfather, was convicted of the felony and sentenced to ten years' penal servitude. Dr. Wilson met with an instance in which a girl at the age of 13 years and 6 months gave birth to a full-grown child; conception must have taken place when she was 12 years and 9 months old. ("Edin. Med. Journ.," October, 1861. See also Casper's "*Vierteljahrsschrift*," January, 1863, p. 180.) Mr. Robertson mentions the case of a factory-girl who became pregnant in the eleventh year of her age. In another communicated to me, a girl menstruated at 10 years and 2 months, and became pregnant when 11 years and 8 months old.

Age at which menstruation ceases. Menstrual climacteric.—The average age at which this function ceases in women, is usually from 40 to 50 years; but as it may commence early, so it may continue late in life. In one case it has been known to cease at the age of 23, and in other instances it has continued up to the age of 66 and even of 75 years. (Whitehead, *op. cit.*, p. 145 et seq.) Dr. Royle describes three cases, in two of which menstruation continued up to the age of 67. ("Med. Times and Gaz.," Nov. 1860.) Mr. Thomas met with a case in which a woman had ceased to menstruate at the age of 45, but the discharge suddenly reappeared after an attack of illness when she had reached the age of 69. The discharge appeared several times, but not with monthly periodicity. It seems that her mother and sister had also menstruated at the ages of 69 and 60 respectively. ("Med. Times and Gaz.," Aug. 7, 1852, p. 148.) In a case which occurred to Capuron, it continued beyond the age of 60 (*op. cit.*, p. 98); but a more remarkable case, both of late menstruation and late pregnancy, is quoted by Orfila from Bernstein. A woman, in whom the function appeared at 20, menstruated until her ninety-ninth year. Her first child was born when she was 47, and her seventh and last when she was 60. ("Med. Leg.,"

4ème ed. 1848, vol. 1, p. 257 ; see also Briand. "Man, Complet de M^él. Lég.," 1846, p. 137.) From these facts, it is clear that it is impossible to fix the age of a woman by the period at which this "change of life" occurs. At the best, it can only be an average of a certain number of instances.

Other cases are recorded on good authority. Dr. Whitehead communicated to the "Lancet," 1866, the following facts. He was called to a lady, æt. 77, suffering from uterine hemorrhage. Upon inquiry, he found that she had menstruated monthly up to the time at which he saw her. The discharge lasted from four to five days, and had then left her; but on this occasion it had been very profuse. She was restored by the usual remedies. Other cases are reported in the "Amer. Jour. of Med. Sciences" (Jan. 1845, p. 107). In one of these, a nun, the menses ceased at 52; at the age of 62 they reappeared, and so continued regularly, until she was last seen at the age of 73. In another instance, a nun, aged 90, had regularly menstruated from 15 to 52. The menses then ceased, but they reappeared at the age of 60 without pain, and had occurred regularly every month since that date. Her health had been good throughout.

From observations made on four hundred women by Dr. Cohnstein, it appears that the menstrual function is of the longest duration in women who menstruate early, are married, have more than three children, nurse their children themselves, and cease child-bearing between the ages of 38 and 42. ("Brit. Med. Jour.," May, 1873.)

Is it possible for a woman to become pregnant after menstruation has ceased?—It is commonly asserted and believed that, after the cessation of menstruation, a woman is sterile. This is doubtless the general rule; but in a medico-legal view it is necessary to take notice of the exceptions. Mr. Pearson, of Staleybridge, communicated to the "Lancet" some years ago, the case of a lady, aged 44, who up to September, 1836, had given birth to nine children. After this the menses appeared only slightly at the regular periods until July, 1838, when they entirely ceased. Owing to this, she supposed that she was not liable to become pregnant; but on the 31st of December, 1839—therefore eighteen months after the entire cessation of the menses—she was delivered of her tenth child. Hence conception must have taken place at from eight to nine months after the final cessation of the discharge.

Latest age for pregnancy. Fecundity.—As a rule, women rarely conceive after the age of 45. At and beyond this age, they have not often intercourse with young and vigorous men. Menstruation may continue up to 50 and 52 years. The age at which women commonly cease to be impregnated, ranges from 45 to 50. It has been observed, that out of 10,000 pregnant women, there were only three above the age of 50 years. ("Ann. d'Hyg.," 1873, 2, p. 150.) Many exceptional instances are, however, recorded of women advanced in life bearing children. A case is reported in which a well-formed woman, who had been married nineteen years, did not bear a child until she had reached the age of *fifty*. (Schmidt's "Jahrbücher d. Med.," 1838, S. 65; Henke's "Zeitschrift," 1844, S. 251.) In this case it is stated that menstruation had ceased two years before conception. Rüttel observed in twelve

women that they bore their last children at ages varying from 45 to 50 years. Ottinger met with an instance of a woman bearing a child at 50; Cederschjald with another where the woman was *fifty-three*, and menstruation still continued. Haller records two cases in which women at *sixty-three* and *seventy* respectively bore children. (Briand, "Man. Complet de Méd. Lég.," p. 137.) But these are doubtful instances, contrary to all modern experience. Neuermann has drawn up a table in reference to the late ages of life in which women have borne children. Out of 1000 cases in 10,000 births, he found that 436 children were borne by females at the ages respectively:—

Of 41 years	101	Of 48 years	8
42 "	113	49 "	6
43 "	70	50 "	9
44 "	58	52 "	1
45 "	43	53 "	1
46 "	12	54 "	1
47 "	13						

A case was communicated to the "Medical Gazette" (vol. 39, p. 950), by Dr. Davies, of Hertford, in which a woman was *fifty-five* years of age when her last child was born; she had menstruated up to that time. Dr. Barker, U. S., has found that the retention of this power of child-bearing depends not so much on the continuance of menstruation as on the state of the ovaries. These organs usually become atrophied in women between the fortieth and the fiftieth year, but in exceptional cases this change may not take place until from one to four years later. When the ovaries have undergone this senile atrophy the woman is permanently sterile. He asserts that not a single authenticated instance has been known of a woman over *fifty-five* years of age who has given birth to a child, except Sarah, the wife of Abraham. A woman over *fifty-five* years is past the age of child-bearing. ("Med. Times and Gaz.," 1875, vol. 1, p. 186.)

In *Lord v. Colvin* (Vice-Chancellor's Court, July, 1859), one of the questions raised was whether a woman, æt. 52, who had been married thirty years without having had children, had then passed the age of child-bearing: her issue would in that case take the benefit of certain property under a will. It was decided that the woman had not reached an age at which it could be said to be impossible that she might bear children. In a return of the Registrar-General for Scotland (Feb. 1862), it is stated in the table for Glasgow, that one mother who was only 18, had had four children, one who was 22 had had seven children, and of two who were only 34, the one had had thirteen and the other fourteen children. On the other hand, two women became mothers as late in life as at 51, four at 52, and one mother was registered as having given birth to a child in the 57th year of her age. We cannot therefore pretend to fix the age beyond which pregnancy may not occur. Questions of this kind have an important bearing on the subject of legitimacy; and unless the law looks to something more than ordinary professional experience in such matters, the decisions of courts must be inequitable. In two recent cases, however, it appears to have been assumed that a woman could not bear a child after the age of 53. This was the decision of the

Master of the Rolls in *Price v. Bousted*, and more recently the decision has been followed by Kindersley, V. C., in *Haynes v. Haynes* (Feb. 1866). The petition in this case involved the question whether a single lady, aged 53, in December, 1865, could be considered as past child-bearing, and it was decided in favor of this assumption. These decisions are not reconcilable with the cases given above.

In France the legitimacy of a child was disputed because the mother at the time of its birth was 48; but the claim was allowed. M. Stolz refers to three cases of married women bearing children at the ages of 45, 48, and 51 respectively. In two of these cases the pregnancy was mistaken for dropsy and treated as such. ("Ann. d'Hyg.," 1873, 2, p. 151.)

Causes of sterility.—The causes of sterility in the female system are very numerous. Some of them depend upon peculiarities of constitution,—the sexual organs being well formed and developed; others upon latent changes or congenital defects in the uterus and its appendages, only discoverable by an examination after death. Sterility rarely becomes a medical question in contested cases of legitimacy; for a claim on the part of a person to be the offspring of a particular woman, unless she were in collusion with the claimant, could only be made after her death: and if not disproved by medical evidence, showing that the woman could not have borne children, it would in general be easily set aside by circumstances. It may be most important to prove that a woman was in such a bodily condition that she never could have conceived or borne a child. If the uterus, ovaries, or other parts were congenitally defective or absent, or if there were external sexual malformation, accompanied by occlusion or obliteration of the vagina, a medical witness could have no difficulty in saying that the woman must have been sterile. ("Med. Times and Gaz.," Jan. 23, 1858, p. 96.) A mere occlusion of the vagina, removable by operation, does not necessarily indicate sterility, for the internal parts may be healthy and sound.

Medico-legal relations of the subject. Divorce.—Sexual malformation, involving impotency or sterility, constitutes one of the *canonical* impediments to marriage, and if matrimony be contracted by a party laboring under such malformation, the contract is voidable. The impediment constituting impotency may arise either from malformation, from that which the law calls frigidity of constitution, or any physical cause of whatever nature which may render intercourse impossible. When the physical defect is not apparent, or when it is alleged to be irremediable, a continued cohabitation of three years is required before a suit can be entertained (Ayliff's "Parergon"); but according to Oughton—"hæc triennalis expectatio non est necessaria ubi statim possit constare de impotentiâ coeundi." A suit for a sentence of nullity may be promoted by either party, and the medical proof required to found a sentence must be such as to satisfy the court that the incapacity pleaded was in existence at the time of the marriage, and that it still remained without remedy. There should be no delay in instituting the suit, and there should be proof that the impediment was not known to the complaining party at the time of the contract. A longer delay in making

the complaint is allowed to a female, without prejudicing her case, than to a male, by reason of the modesty of her sex.

In a suit which came before the Ecclesiastical Courts in 1845, a singular question arose whether, when there was a capacity for sexual intercourse on the part of a woman, with a certainty that from physical defect it could never be prolific, this was sufficient to entitle the husband to a divorce. On the part of the woman it was insisted that in order to entitle a party to a sentence of divorce, there must be an utter *impossibility* of sexual intercourse. The case, it was argued, was one of mere sterility, which was no ground for a sentence. Dr. Lushington, in pronouncing sentence, said that mere incapability of *conception* is not a sufficient ground whereon to found a decree of nullity. The only question is, whether a female is or is not capable of sexual intercourse; or, if at present incapacitated, whether that incapacity admits of removal. A power of sexual intercourse is necessary to constitute legally the marriage-bond; and this intercourse must be ordinary and complete, not partial and imperfect; yet it would not be proper to say that every degree of imperfection would deprive it of its natural character. If it be so imperfect as to be scarcely natural, it is, legally speaking, no intercourse at all. As to conception, there is no doubt that the malformation is incurable. If there was a reasonable probability that the female could be made capable of natural coitus, the marriage could not be pronounced void; if she could not be made capable of more than an incipient, imperfect, and unnatural coitus, then it would be void.

From cases hitherto decided, it appears that in order to justify a decree of divorce on the ground of impotency or sterility, the impediment to intercourse or procreation should be established by good medical evidence, and it must be *apparent* and *irremediable*; it must also have existed before the marriage of the parties, and have been entirely unknown to the person suing for the divorce; if it has supervened after the marriage, this is no ground for a suit. The nature of the impediment is to be determined by private medical opinions or affidavits, based on an examination of *both* parties. Such an examination must be voluntary on the part of the man or the woman. The judge of the court cannot order it against the wish of the party. All that he can do is to decide in the absence of evidence of the kind, and this may be adverse to the party refusing. In the case of *Hewitt v. Pery* (Divorce Court, July, 1873), a suit for nullity, Sir J. Hannen gave his decision in favor of the husband and against the wife. She refused to submit to an examination, and abstained from presenting herself as witness in the case. The case was remarkable in other respects. The evidence of the husband was to the effect that there had been more than three years' cohabitation, but no consummation of the marriage. There was no structural impediment in the way of consummation in the wife's person; but whenever an attempt at intercourse was made, it brought on an attack of hysteria, and this rendered it practically impossible. A decree nisi for annulling the marriage was granted to the husband; but the learned judge at the same time observed, that such a decree could only be granted on the ground that there was a *physical* difficulty. Thus it must not be merely a wilful refusal on the part of the wife. This alone would not justify legal interference; it must be

shown, as in this case, that injury may be done to health by inducing an attack of hysteria or other disorder. Dr. Oldham has informed me that several cases of this kind have come before him. It may be regarded as incapacity, not from structural defect, but from a general disturbance to the system induced by the attempts at intercourse.

Dr. St. Clair Gray has recently pointed out another condition in a woman, which may prevent consummation of a marriage and give rise to a suit of nullity. This has been called *vaginismus*. In this disease there is a peculiar sensitive state of parts, whereby from "excessive nervous irritability of the vagina," any attempt at sexual intercourse or even any pressure made in the vicinity, causes intolerable pain to the woman. He describes three cases which have fallen under his notice. In one, a woman, æt. 38, had been married thirteen years, but in consequence of the intolerable pain produced, her husband had not been able to have intercourse with her. An examination showed that the hymen was persistent, but the parts were so highly sensitive that a touch with the finger only produced great suffering. Nine years passed without any change in her condition. In two other cases of married women there was a similar state of parts—the hymen being also persistent in both. One had been married four and the other seven years, and they had had no children. The hymen was destroyed by operation; the sensibility of the parts disappeared; and one gave birth to four and the other to three children. ("Glasgow Med. Jour.," May, 1873.) It is clear, therefore, that *vaginismus* would be no legal ground for divorce according to the law of England, because the defect is remediable—a fact proved by two of the cases described. In the three cases, the women labored under no physical malformation. They were in every respect healthy and well formed.

There is one remarkable circumstance with respect to these suits of nullity; namely, that in nearly all of them, the suit is by the woman against the man; although there is no reason whatever to suppose that impotency and sexual malformation are more common in males than malformation and sterility in females. We rarely hear of a husband instituting a suit of divorce on the ground of sterility (incapacity of procreation) in the wife; it is, I believe, in most instances, that the wife promotes the suit on the ground of impotency or incapacity of intercourse in the husband. The difficulty of establishing incapacity in the female, and the facility of proving impotency from physical causes in the male, may probably account for this difference. Suits of this kind are sometimes instituted many months and years after the union of the persons; but it is probable that the desire for separation in such cases often depends on some cause which the law would not recognize as sufficient of itself, while it would admit a plea of impotency. The French law very judiciously applies the principle of condonation to such cases, so that no suit for nullity of marriage can be entertained, if cohabitation has continued for six months after the discovery of the personal defect. The laws of England and France differ in reference to personal defects. Impotency or incapacity of intercourse in a woman is in England a sufficient ground for annulling the contract, but not so in France. In a case reported by

M. Tardieu, it is distinctly stated that the law has not placed impotency in the female among the causes for nullity of marriage. ("Ann. d'Hyg.," 1872, 2, pp. 153, 155.)

The validity of a marriage cannot be disputed, on the ground of physical incapacity, after the death of one of the parties. This does not render a marriage void, but only voidable. It is a matter purely of personal complaint or grievance. Third parties cannot be admitted to institute a suit of nullity after the death of husband or wife. In an administration suit, July, 1868, the plaintiff claimed as the lawful husband of the intestate. The defendants, who were her next of kin, alleged that the plaintiff was not her lawful husband on the ground of physical incapacity, and that the marriage had never been consummated. Sir J. Wilde delivered judgment against the defendants, saying that the suit of nullity was a personal one, and as this had not been instituted during the life of the woman, the validity of the marriage could not now be contested.

In treating of sexual identity (*loc. cit.*) M. Tardieu remarks that marriage implies the lawful union of a man and woman: that such a contract cannot be entered into except between persons who are of different sexes. When the sex is disputed, the doubt can be removed only by an anatomical and physiological examination of the person. The intervention of a medical expert is indispensable in such a case, and the object of such intervention is perfectly defined. The problem for solution may be stated in these simple terms. Is the person married as a woman—a malformed woman—impotent and incapable of sexual intercourse? In this case, according to the strict interpretation of the law of France, there is no ground for nullity of marriage. Is the person a malformed man, presenting some doubtful appearances of the female sex? In this case there has been no legal marriage. It is null *ab initio*. Assuming that there are no beings entirely deprived of sex, there may be cases, although rare, in which a mixture of the organs of the two sexes may be found in the same person. Such a being is incapable of entering into the marriage contract, since whatever may be the sex of the person with whom the contract is made, there must be identity of sex, and therefore nullity of marriage.

RAPE.

CHAPTER LIX.

SOURCES OF MEDICAL EVIDENCE.—RAPE ON INFANTS AND CHILDREN.—MARKS OF VIOLENCE.—PURULENT DISCHARGES FROM THE VAGINA.—EVIDENCE FROM GONORRHOEA AND SYPHILIS.—RAPE ON GIRLS AFTER PUBERTY.—DEFLORATION.—SIGNS OF VIRGINITY.

RAPE is defined in law to be the carnal knowledge of a woman by force, and against her will. The definition under the proposed new Criminal Code takes a wider range. “Rape is the act of having carnal knowledge of a woman without her conscious permission, or with her conscious permission, if such permission is either extorted by force or fear of bodily harm, or obtained by personating her husband, or by falsely pretending that the act is necessary, or will be advantageous to her for any medical or surgical purpose.” Medical evidence is commonly required to support a charge of rape, but it is seldom more than corroborative; the facts are, in general, sufficiently apparent from the statement of the prosecutrix. There is, however, one case in which medical evidence is of some importance,—namely, when a false accusation is made. In some instances, as in respect to rape on infants and children, the charge may be founded on mistake; but in others there is little doubt that it is often wilfully and designedly made for motives into which it is here unnecessary to inquire. The late Professor Amos remarked, that for one real rape tried on the Circuits, there were on the average twelve pretended cases! In some few instances these false charges are at once set aside by medical evidence—in others, medical men may be sometimes the dupes of designing persons; but in the majority, the falsehood of the charge is proved by inconsistencies in the statement of the prosecutrix herself. I am informed that in Scotland, where there is a public prosecutor, and a careful preliminary inquiry, false charges of rape are exceedingly rare. The *consent* of the girl does not excuse or alter the nature of the crime when she is under ten years of age, since consent at this period of life is invalid; and the carnal knowledge of such a girl is rape in law, and is made a felony by the 24 & 25 Vict., c. 100, s. 50. Even the solicitation of the act on the part of a child does not excuse it.

Under the new Code, a man is guilty of rape who carnally knows any girl under the age of twelve, even if she consents, whether he knows her age, or believes her upon good grounds to be above that age. The punishment for this crime, as well as for rape, generally is penal servi-

tude for life. A man who carnally knows or attempts to know any girl above the age of twelve, and under the age of thirteen years, even if she consents, and whether he knows her age or not, is guilty of an offence, and liable to a punishment of two years' imprisonment.

[The provisions of the Revised Criminal Code of Pennsylvania, Act of 31st March, 1860, §§ 91, 92, 93, upon this subject, are as follows:—

§ 91. If any person shall have unlawful carnal knowledge of a woman, forcibly and against her will, or who being of the age of fourteen years and upwards, shall unlawfully and carnally know and abuse any woman child under the age of ten years, with or without her consent: such person shall be adjudged guilty of felonious rape, and on conviction, be sentenced to pay a fine not exceeding one thousand dollars, and to undergo an imprisonment, by separate or solitary confinement at labor, not exceeding fifteen years.

§ 92. It shall not be necessary, in any case of rape, sodomy, or carnal abuse of a female child under the age of ten years, to prove the actual emission of seed, in order to constitute a carnal knowledge, but the carnal knowledge shall be complete upon proof of penetration only.

§ 93. If any person shall be guilty of committing an assault and battery upon a female, with intent, forcibly and against her will, to have unlawful carnal knowledge of such female, every such person shall be guilty of a misdemeanor, and, on conviction, be sentenced to pay a fine not exceeding one thousand dollars, and to undergo an imprisonment, by separate or solitary confinement at labor, not exceeding five years.—P.]

The duty of a medical witness on these occasions is very simple; and perhaps this will be best understood by considering the subject in relation to females at different ages. On being called to examine a person on whom a rape is alleged to have been committed, the first circumstance which a practitioner should notice is the precise *time* and date at which he is summoned, taking an early opportunity of comparing his watch with some neighboring clock. This may appear a trivial matter, and one wholly irrelevant to the duties of a medical practitioner; but it is to be observed that the time at which a surgeon is required to examine a prosecutrix, may form a material part of the subsequent inquiry. It will be highly important to the defence of a person accused, if it can be proved that the female did not take the earliest opportunity to complain; and it may be also the means of defeating an alibi falsely set up for the defence. Medical evidence in cases of rape may be derived from four sources: 1. Marks of violence about the genitals. 2. Marks of violence upon the person of the prosecutrix or prisoner. 3. The presence of stains of the spermatic fluid or of blood, on the clothes of the prosecutrix or prisoner. 4. The existence of gonorrhœa or syphilis in one or both. This evidence will vary according to the age of the female and other circumstances.

RAPE ON INFANTS AND CHILDREN.

The sexual organs should in these cases present marks of injury if the crime has been completed, and there has been *any resistance on the*

part of the child: for it is impossible to conceive that forcible intercourse should take place without the production of ecchymosis, the effusion of blood, or a laceration of the pudendum. Even without reference to manual violence on the part of the assailant, if an adult, the size of the male organ must generally cause much local injury in the attempt to enter the vagina of a child. If the violation has taken place within two or three days, the appearances presented by the parts may be as follows: 1. Inflammation, with more or less abrasion of the lining membrane. 2. A muco-purulent discharge from the vagina of a ropy consistency, and of a yellowish or greenish-yellow color, staining and stiffening the linen worn by the girl; the mucous membrane of the urethra is inflamed, rendering the discharge of urine painful. 3. In recent cases blood may be oozing from the abraded membrane, or clots of blood may be found deposited in the vulva. 4. The hymen may be entirely destroyed, or (what is more commonly observed) it may present on careful examination one or more slight lacerations. Owing to the inflamed state of the parts, the proper examination of the hymen is rendered difficult—any attempt to separate the thighs for that purpose causing great pain. For this reason also, the child walks with difficulty and complains of pain in walking. 5. Lastly, the vagina may be unnaturally dilated.

It has been propounded as a serious question whether a rape can be perpetrated on children of tender age by an adult man; and medical witnesses at trials have adopted conflicting opinions. Some are inclined to regard all such charges as unfounded, and to seek for other medical explanations of the symptoms above described. This practice has been carried of late years to an undue extent, simply because many of these charges have been proved to be false; but common experience, supported as it is by the accurate observations of Casper ("Ger. Med.," vol. 2, p. 130), show that there is too frequently a real foundation for the charge in reference to children, and that a girl is not to be discredited merely because of her tender age. This would be conferring impunity on the acts of a vile class of offenders. In all cases there should be good medical evidence and a corroboration from circumstances.

For the *legal* establishment of the crime, proof of penetration only is demanded (24 & 25 Vict., c. 100, s. 63), and a sufficient degree of penetration to constitute rape in law may take place without necessarily rupturing the hymen. There must be medical evidence to show that, in a special case, there was actual penetration—the degree of penetration being quite immaterial. It is true that there could not be a complete introduction of the adult male organ into the vagina of a child without a rupture or laceration of the soft parts; but the absence of such marks of violence would not justify a medical witness in denying the perpetration of the crime, since the law does not require proof either of a complete or of a violent introduction. It has been decided that penetration to the vulva alone is sufficient to constitute this crime. Medical men have sometimes fallen into an error on this point, considering that when the hymen was entire, rape could not have been committed; but the Statute Law says nothing about the rupture of the hymen as a necessary part of the medical evidence; it merely requires from the medical witness proof of vulval penetration, this may occur and the hymen remain

intact. In *Reg. v. Harris*, Bristol Lent Ass., 1873, the prisoner, an adult, was convicted of rape on an infant only *seven months* of age. According to the medical evidence there was no great amount of violence to the genital organs. The parts were swollen, and there was slight excoriation about the labia minora, with a small discharge of blood. The hymen and the vagina had escaped laceration. According to the medical evidence, seminal fluid was found on the person of the child. In this case there might have been penetration of the male organ to the vulva. In so young a child there could have been no resistance, and the act might therefore have been perpetrated without leaving any serious marks of violence.

In Scotland this question came formally before the judges in the case of *Macrae* (High Court of Justiciary, 1841). It was insisted by the prisoner's counsel that there should be proof of full and complete penetration; and there was no sufficient evidence to show that penetration had taken place into the canal of the vagina beyond the vulva. Lord Meadowbank charged the jury to the effect that the evidence of the prisoner's guilt was complete; that scientific and anatomical distinctions as to where the vagina commenced were worthless in a charge of rape; and that by the law of Scotland it was enough if the woman's body was entered. In a case like this, where there was no evidence of the emission, and the girl was young, he did not consider it necessary to show to what extent penetration of the parts had taken place, or to prove that it had gone either past the hymen, into what was anatomically called the hymen, or even so far only as to touch the hymen. The prisoner was convicted. ("Cormack's Edin. Jour.," January, 1846, p. 48.) I am informed that, up to the date of the case of *Macrae*, it had been the practice with the Scotch judges to require proof of *full and complete* penetration. See on this question a paper by the late Dr. Easton. ("Glasgow Med. Jour.," July, 1859, p. 129.) Under the new Criminal Code, these technical questions can no longer arise, for carnal knowledge is therein defined to be the penetration of the organ known to any the least degree by the male organ of generation.

[The same rule is observed in this country; *some degree of penetration* must be proven, but neither rupture of the hymen nor emission need be established.—R.]

Marks of violence on the pudendum.—When there are no marks of violence or physical injury about the pudendum of a child, whether because none originally existed, or they existed and had disappeared in the course of time, a medical witness must leave the proof of rape to others. He can only answer questions of possibility or probability, according to the special facts proved. It is, however, in all cases his duty to be guarded in giving an opinion that a rape has been perpetrated, when there is a total absence of marks of violence on the genitals. It is true that rape in a legal sense may be perpetrated without necessarily producing such marks on a child, but then the proof of the crime will not depend on *medical evidence* only. The absence of marks of violence on the genitals, when an early examination has been made, furnishes a strong presumption that rape has *not* been committed on these young persons. It is obvious that a false charge might be easily made and

sustained, if medical opinions were hastily given on the statements of a mother and child, when there was no physical appearance to corroborate the accusation. See on this subject a paper by M. Toulmouche. ("Ann. d'Hyg.," October 1, 1868, p. 338.)

Supposing at the period of examination no marks exist, it may be necessary to consider whether there has been time for them to disappear after the alleged perpetration of the offence; but in such cases it is rarely in the power of a medical witness to express an affirmative opinion of the perpetration of the crime: he should leave this to be proved by the general and circumstantial evidence. Casper met with a case in which a man, æt. 37, committed a rape on a girl only eight years of age: he was seen in the act, and defended himself on the plea of drunkenness. The girl was examined by a medical man on the day following,—the labia were then reddened, and there was an injection of the membrane at the entrance of the vagina which was very sensitive. As an illustration of the rapidity with which the marks of rape disappear in young children, when not attended with great physical injury, it may be stated that this girl was carefully examined by Casper *eleven days* after the assault. The sexual organs were then in their natural state; there was not the least appearance of local injury, and no inference could have been drawn at this date that the girl had been subjected to any violence.

Medical practitioners are not always sufficiently careful in the inferences which they draw from an examination of children at distant periods after an alleged rape. They allow themselves to be deceived by a plausible story, apparently consistent, and thus see, or think they see, proofs of rape on examining the sexual organs of a girl many weeks after the alleged perpetration of the crime; whereas, had the girl been brought before them as a casual patient, and no suggestion of violent intercourse had been made, they would have probably ridiculed the idea of basing a charge of rape on so slender a foundation. The delay in having the examination made, unless satisfactorily explained, is in itself always a suspicious circumstance. In one case sent for trial to the Assizes, but rejected by the Grand Jury, a medical man gave strong evidence that a rape had been committed on a girl seven years of age, although he did not examine her until *six weeks* had elapsed from the date assigned by the parents for the alleged perpetration of the crime!

On the other hand, when marks of violence on the genitals are present, they must not be hastily assumed as furnishing proofs of rape; for cases are recorded in which such injuries have been purposely produced on young children by women, as a foundation for false charges against persons with a view of extorting money. The proof or disproof of facts of this kind must rest more upon general than on medical evidence, unless the injuries obviously indicate the use of some weapon or instrument. It should be remembered that the hymen is not always present in young children; it may be, according to some, congenitally deficient, or what is more probable, it may have been destroyed by ulceration or suppurative inflammation of the parts,—a disease to which female infants of a scrofulous habit are very subject. The mere absence of this membrane,

therefore, can afford no proof of the perpetration of the crime, unless we find traces of its having been recently torn by violence.

Other and more important deductions may, however, be drawn from the presence of severe injuries on the genitals, *i. e.*, of rupture, or laceration of the vagina or perineum. It is difficult to obtain accurate medical reports of these cases as they occur in England: but it is quite clear that the male organ may produce much physical injury whether the child does or does not resist the attempt. (Casper's "Vierteljahrsschrift," April, 1863, p. 337.) A youth was convicted of murder at the Chelmsford Assizes in 1874-5. He had committed rape on a girl with so much violence as to cause her death. It was found that the rectum and part of the intestines had been forced out in the act of intercourse, which, according to the confession of the prisoner, had taken place after death. Dr. Chevers, in referring to Indian experience, says that in a large proportion of rapes on children, it was very clearly proved that rather severe injuries had been inflicted on them. In the "Nizamut Adawlut Reports" (1853-5), there are several instances recorded in which the vagina was lacerated. Out of 66 trials for rape, there were 25 convictions: and in one-half of these, the females were under the age of *twelve* years. In one case of a girl *æ*t. 12, there was a rupture of the lower part of the vagina to the extent of half an inch. In another, a child of six but apparently much younger, had suffered as a result of rape, from rupture of the hymen and laceration of the perineum and vagina. In one instance the violence proved fatal, but the medical particulars were not given. ("Med. Jur. for India," p. 468.) When it is alleged that injuries have been intentionally produced on the genitals of a child by mechanical means, with a view of extorting money in laying a false charge of rape, the medical evidence can do no more than show that a girl with such appearances about her sexual organs, has suffered with some violence applied to the parts, but whether by the human member, or any other physical means, it would be impossible to say. The only chance of getting at the truth in such a case is by a rigorous cross-examination of the mother and the child in the absence of each other.

In April, 1840, Dr. Brady communicated to the Dublin Association of Physicians, a case of alleged rape on a female infant only eleven months old, in which the violence done to the genitals proved fatal.

In January, 1858, a girl seven years old was brought into Guy's Hospital, owing to injuries resulting from a perpetration of rape by a boy under seventeen years of age. About half an hour had elapsed; she was then examined by Mr. Hicks, the house-surgeon, and he found that there was a complete destruction of the hymen with a laceration of about one-eighth of an inch extending into the perineum. There had been profuse bleeding, as the clothes were saturated with blood. There was then no complaint of pain, and there were no scratches or marks of violence on any part of the body. There was no discharge of a purulent kind. The child was of a scrofulous habit: but she was not suffering from vaginitis, and appeared in other respects perfectly healthy. I saw the girl with Mr. Hicks about forty-eight hours after the occurrence; the bleeding had then ceased, and the extent of the lacerations was very perceptible. There was no discharge of any kind from the vagina, and

no inflamed or swollen condition of the parts. The boy was examined by Mr. Hicks about an hour after the perpetration of the rape, and although he had been under strict custody, and had had no opportunity of changing his clothes, there was *no blood* found about his private parts, or on his clothing. It is probable, as the boy was interrupted in the act by the screaming of the girl, that he suddenly withdrew after having caused the laceration, and that the bleeding was an after-effect of oozing from the ruptured vessels. This is an important fact, because, had not the circumstances been known, the absence of blood on his person might have been construed into a strong proof of innocence. Dr. Sawyer met with a case in which a rape was committed on a girl æt. 5. There was a bruised and swollen state of the genitals: the hymen was not ruptured and there was no laceration of parts. In spite of this, a large amount of blood had been lost. This bleeding, in his opinion, took place from the hymen, which was in a highly congested state. The man who had perpetrated the crime was examined soon afterwards, but no appearance of blood was found on his organs; there were a few stains only on the front of his clothing. ("New Orleans Med. Gaz.," 1858, p. 283.) A case occurred to Mr. Sells, of Guildford, in 1863, in which he found, on examining the person of a girl said to have been violated, laceration of the hymen, a clot of blood recently effused lying on the vulva, and the thighs of the child smeared with blood, quite fresh; there was also blood on the sheets of the child's bed. The next morning he examined the accused, but he could find no trace of blood upon him or on the clothing which he wore at the time of the alleged assault. In this case, as there was a failure of identity, the accused was discharged.

Sometimes owing to the violence used, the parts are much lacerated; and inflammation, followed by sloughing or mortification, may set in and destroy life, especially in children of an unhealthy habit. Care should be taken that the symptoms of a malignant form of disease (*noma*), to which female children when in a dirty or neglected state are liable, are not mistaken for the results of criminal violence.

Some cases are reported, from which it would appear that men have narrowly escaped conviction for a crime which had really not been perpetrated. Dr. Percival, in his "Medical Ethics" (3d ed., 1849, p. 117), has related a case which has been the subject of frequent quotation and comment in reference to false charges of rape. A girl æt. 4 was admitted into the Manchester Infirmary in February, 1791, on account of a mortification of the female organs and general depression of strength. She had been in bed with a boy fourteen years old, and it was supposed that he had taken criminal liberties with her. The mortification increased, and the child died. The boy was tried on a charge of rape at the Lancaster Assizes, but acquitted on evidence being adduced that several instances of a similar disease had appeared among girls about the same period of time, in which there was no reason to suspect injury or guilt. In one of these cases there was typhus fever with a mortification of the genitals. There was no cause of death discoverable on inspection; the lumbar glands were of a dark color, but all the viscera were sound. This case, with the whole of Mr. Kinder Wood's paper on the subject, has been republished by Dr. Kesteven. ("Med. Times and Gaz.," 1859,

April 23 and 30.) A case of this disease (*noma pudendi*), but in which no charge of rape was made, was referred to me in December, 1865. E. A. R., a girl æt. 5, died suddenly under circumstances which led to a suspicion that poison had been administered to her. There was congestion of the lining membrane of the stomach, but no poison was found in the body, and there was no trace of the action of poison. When the body was inspected, the genitals externally and the skin around and beyond the anus, were intensely inflamed, swollen and ulcerated, and in an approaching state of gangrene or slough. The hymen at the entrance was ruptured and the lining membrane of the vagina and uterus was highly inflamed—of a dark purple color with softening and disorganization of substance. The inguinal glands were enlarged on both sides. The child was in a neglected and dirty state, and died from exhaustion produced by the disease and want of proper food and support. Deceased was seen by a medical man shortly before her death, and the state of the genitals was only discovered by accident, the mother having made no observation about it. When questioned on the subject, she said the girl had been blown down about a fortnight before and had injured herself by falling on some thorns. This was quite inadequate to account for the condition of the parts. There was no doubt that this was a case of noma rendered fatal by neglect in an unhealthy child. Had any man been seen noticing this child, a charge of rape might easily have been founded upon the state of the genital organs.

On the other hand, fatal injury may be done to these organs in criminal assaults. Mr. Colles has reported a case in which a rape was committed by an adult on a child eight years old; it terminated fatally from peritonitis, as a result of the violence, six days after the assault. The child stated that the accused had had forcible connection with her, causing much pain and loss of blood. There were no marks of violence (bruises?) externally, but the orifice of the vagina was lacerated in its entire circumference, and the perineum was nearly torn through. It was found, on inspection, that the orifice, as well as the whole of the vagina, was in a state of gangrene, and its posterior wall had been lacerated at its line of junction with the uterus to the extent of an inch. There was no ulceration; the labia and clitoris had not undergone any change. ("Med. Times and Gaz.," June 2, 1860, p. 560.) The prisoner subsequently confessed his guilt. A case was communicated by Dr. M'Kinlay to the "Glasgow Medical Journal" (July, 1859, p. 140), which proves that extensive injuries may be produced on a child by the act of violation. The girl in this instance was about six years of age, and very intelligent. From her description of the assault, it appears that she fainted, probably owing to the severity of the pain. When examined, it was found that the vagina was ruptured in various directions. One laceration extended from the lower part downwards, dividing the recto-vaginal septum and perineum down to the verge of the anus. There was a lacerated opening in the coats of the rectum; the orifice of the vagina was lacerated upwards as well as laterally; the parts were raw, swollen, and very tender. When the child was first seen, there was blood on the limbs and clothes: she recovered from these serious injuries in about two months. In a case of alleged rape, it was a ques-

tion raised in favor of the prisoner, whether rupture of the perineum could or could not be produced in rape on a girl. Some eminent members of the profession appear to have doubted the possibility of a rupture being produced under these circumstances (see Sir W. Wilde's paper, "Dub. Med. Journal," February, 1859); but the facts here recorded show that such an opinion is erroneous.

Purulent discharge from the vagina. Vaginitis. Infantile leucorrhœa.—The existence of a purulent discharge from the vagina as a result of vaginitis or inflammation of the vagina, has been frequently adduced as a sign of rape in girls. The parents, or other ignorant persons who examine the child, often look upon this disease as a positive proof of impure intercourse; and perhaps lay a charge against an innocent person, who may have been observed to take particular notice of the child. A purulent discharge with aphthous ulceration of the mucous membrane is occasionally a result of vaginitis or inflammation of the vagina. It may arise from dentition, or local causes of irritation—as worms or uncleanly habits, and is observed especially in children of a scrofulous habit. It is frequently met with in girls up to six or seven years of age: and children thus affected have been tutored to lay imputations against innocent persons for the purpose of extorting money. This state may commonly be distinguished from the effects of violence, either by the hymen being entire—or by the non-dilatation or laceration of the vagina or perineum—by the red and inflamed condition of the mucous membrane—and the abundance of the purulent discharge, which is commonly much greater than that which takes place as a mere result of violence. Capuron mentions two cases in which charges of rape on children were falsely made against innocent persons, on account of the existence of a purulent discharge the nature of which had been mistaken. ("Méd. Lég. des Accouchemens," p. 41.) The late Sir Charles Locock observed that the purulent discharges of female children were attended with redness and swelling of the sexual organs, and were sometimes accompanied with excoriation and sloughing of the skin, owing to the irritating nature of the matter. They are so connected with dentition that they not only appear with the first and second set of teeth, but even when the wisdom-teeth are irritating the system at a mature age. Mr. South, commenting on this statement ("Chelius's Surgery," vol. 1, p. 161), justly remarks that a knowledge of these facts, "is highly necessary, and is very properly insisted on, as there is no doubt that many men have suffered capital punishment from the ignorance of practitioners on this point; and even now, with our better knowledge, it is by no means unfrequent to hear of medical men giving a decided opinion which is almost certainly erroneous upon the gonorrhœal character of pudendal discharges, and thus jeopardizing the character if not the life of an innocent man. In giving his opinion or evidence in such cases, a practitioner is bound to speak with extreme caution, and only on the most incontestable proof (which by a mere examination of parts it is almost impossible for him to attain), before he makes a positive statement as to the gonorrhœal character of a discharge." Although the facts are or ought to be well known to medical men, there is still much popular ignorance in reference to this disease, and false charges of rape on children are now

not unfrequently made. Dr. Kesteven met with a case in which a discharge from the vagina of a child nine years of age, was supposed by the parents to prove that intercourse had been had with her. There was no mark of contusion or violence on or about the pudendum or in the vagina, and the case was very properly pronounced by him to be one of vaginitis. ("Med. Gaz.," vol. 47, p. 372.) A similar case was referred to me, in which a soldier was supposed to have infected a child: but an investigation showed that it was a purulent discharge depending on inflammation of the vagina. In February, 1872, I was consulted in reference to a charge against a father for criminal intercourse with two of his daughters, one of them nine and the other fourteen years of age. If the purulent discharges were gonorrhœal, there was a strong presumption of his guilt; if only of the ordinary kind, arising from vaginitis, he might be innocent, and the accusation made against him false. (See also "Ann. d'Hyg.," 1864, 2, 333, and 1860, 2, 131, 345.)

A gonorrhœal discharge is generally very profuse—much more profuse than that purulent discharge which is simply the result of such violence as is produced in the commission of rape. There is another fact worthy of notice, namely, that the last-mentioned discharge, besides being less profuse, lasts for a much shorter time. Casper has recommended that in doubtful cases another examination of the sexual organs should be made in ten or twelve days. If the purulent discharge has then ceased or is ceasing, there is good reason to believe that it was not the result of gonorrhœa, but of some temporary cause of inflammation in the mucous membrane. ("Klinische Novellen," 1863, p. 10.) Of false charges of rape arising from mistakes on this subject, Casper furnishes various instances (p. 19). The power of distinguishing gonorrhœal or syphilitic discharges from purulent discharges has been much debated in reference to the examination of women under the Contagious Diseases Act. Mr. Henry Lee has especially called the attention of the profession to this subject in a lecture before the Medical Society. In a case which occurred under his own observation, a free purulent discharge from the vagina with a reddened and inflamed mucous membrane, led him to believe that it was derived from gonorrhœal infection; but a week afterwards the inflammation had disappeared, the mucous membrane was of its usual color, and the discharge not more than natural. This caused him to reverse his opinion, and to congratulate himself that he had not unjustly accused the patient. ("Lancet," Feb. 8, 1873, 1, 218.)

Assuming that the surgeon is satisfied, from a careful examination, that the purulent discharge must have existed before the alleged assault, and that it is of the ordinary inflammatory character with which young girls are liable to be attacked, this would not justify him in affirming that no rape had been attempted or perpetrated on the child. Girls laboring under this disease may be the subjects of rape, and it will then be necessary to seek for further evidence in the condition of the hymen, the lining membrane of the vagina and the vulva. If nothing is found beyond what is consistent with disease, there is an absence of medical evidence to prove that any rape has been committed. An aphthous state of the membrane of the vagina must not, under these circumstances, be

ascribed to injury caused by mechanical violence. (Casper's "Gerichtliche Medicin," vol. 2, p. 148.)

Infantile leucorrhœa has been fully investigated by the late Sir W. Wilde, of Dublin. ("Medico-legal Observations," &c., 1853.) This gentleman has collected numerous instances illustrating, in a remarkable manner, the great danger to which innocent persons are exposed by reason of false charges of rape on children. Two of these are especially noticed in his essay. A charge was raised against a respectable man, that he had had intercourse with, and produced disease in, two children. The day and hour were circumstantially given, extorted as it appears from the children by their parent, and the man was put upon his trial. The appearances were such as are usual in these cases,—a purulent discharge from the vagina with some excoriation, but no bruise, laceration, or mark of violence on the pudendum. There had not been any penetration of the vagina. The charge against the prisoner, although unsupported by any affirmative circumstances, received some strength from the admission made by one medical witness for the prosecution,—namely, that the appearances *might* have been the result of violence, and that the discharge *might* have been produced by friction with the member of a healthy man. (Wilde, op. cit., p. 14.) It was proved that the prisoner was not affected either with gonorrhœa or syphilis. Drs. Geoghegan, Churchill, and other medical witnesses of repute, gave testimony to the effect that the child was really laboring under an ordinary form of disease, and that there was no medical indication that it had been subjected to any kind of violence. This testimony was not considered by the court to furnish a complete answer to the charge, since it was inferred that the appearances on the child *might* have been caused by the accused, without any marks of violence being left on the pudendum! So strong was this feeling that, had the case rested here, it is probable the accused would have been convicted upon the unsupported statement of the child. An alibi was, however, clearly proved, and the man acquitted. In this instance, it will be perceived it was alleged that a man who labored under no disease had caused a purulent discharge in a child. At the same time, it was admitted that the pudendum had sustained no violence whatever. Medically speaking there appears to have been not the slightest pretence for charging the accused with the perpetration of rape; the appearances might have or might *not* have been caused in the manner suggested. Under such loose medical evidence as this no accused person would be safe. An acquittal from an unfounded charge would depend upon the accused being able to prove a distinct alibi, *i. e.*, he must prove his innocence. The statement of the child may be simple and artlessly made. At this tender age a girl may be easily induced by the fear of punishment, and by the aid of leading questions put by a parent, to admit that some one had committed an assault upon her. The statement once made may be persevered in, and its inconsistency may not always be brought out by cross-examination.

If the child is really laboring under *syphilis* or *gonorrhœa*, this is, *cæteris paribus*, evidence of impure intercourse, either with the ravisher or some other person; but we should be well assured, before giving an opinion, that the discharge is really of a gonorrhœal, and not simply of

a common inflammatory (purulent) character. The party accused may have been at the time free from the disease, or, if laboring under it, then we should expect to find that the discharge had suddenly made its appearance in the child, with its usual severe symptoms, at a certain interval of time after the alleged intercourse, *i. e.*, from the third to the eighth day. When these conditions do not exist, it is extremely difficult to form a medical opinion on the subject, since there are no certain means, by the microscope or otherwise, of distinguishing common purulent discharges from those which are gonorrhœal or syphilitic. A case occurred to M. Biessy, in which a merely mucous discharge in a girl was pronounced to be syphilitic, and the person who was falsely accused of rape, narrowly escaped conviction. (Briand, "Man. Complet de Méd. Lég.," 1846, p. 81.) The purulent matter of gonorrhœa does not differ microscopically from that produced in other forms of disease.

We should further distinctly satisfy ourselves that gonorrhœa in a child, if it exist, could not have arisen from infection by any accident irrespective of intercourse. This limitation is rendered necessary by the publication of a report of two cases by Dr. W. B. Ryan ("Med. Gaz.," vol. 47, p. 744), in which two sisters, one of one year and the other of four years of age, received the infection by reason of their being washed in a vessel of water with a sponge used by a young woman affected with profuse gonorrhœal discharge. Dr. Ryan clearly traced the origin of the discharge to this unexpected accident. Had an accusation of rape been made against a man laboring under gonorrhœa, it is not at all improbable that this condition of the children, resulting from an unsuspected accident, would have been taken as an unanswerable proof of his guilt. Cases of this kind, thus accurately observed, convey an important caution to medical witnesses, *i. e.*, that they should not infer criminal intercourse merely from the existence of a gonorrhœal discharge, in the absence of marks of violence to the genitals or of other strong corroborative proofs.

As a summary of these remarks with respect to purulent discharges, we may observe that they should not be admitted as furnishing corroborative evidence of rape, except,—1st, when the accused person is laboring under gonorrhœal discharge; 2dly, when the date of its appearance in a child is from the third to the eighth day after the alleged intercourse; and 3dly, when it has been satisfactorily established that the child had not suffered from any such discharge previously to the assault. It may be said, however, that all these conditions may exist, and yet the accused be innocent; for a child may, either through mistake or design, accuse an innocent person. This, however, removes the case entirely from the hands of a medical jurist. (The reader will find much useful information on this subject in a paper by Dr. Penard, "Ann. d'Hyg.," 1860, vol. 2, pp. 130, 345.)

With respect to marks of violence on the *body* of a child, these are seldom met with, because no resistance is commonly made by mere children. Bruises or contusions may, however, be found occasionally on the legs.

RAPE ON YOUNG FEMALES AFTER PUBERTY.

When the crime is committed on a girl from the age of ten to twelve years, the facts are much the same as those already referred to with respect to children below the age of ten years. There is, however, some difference in the legal complexion of the offence. If carnal intercourse be had with the consent of a female at the ages of ten and twelve years, the offender is guilty of a misdemeanor only (24 & 25 Vict., c. 100, s. 51); above the age of twelve years, the consent of the girl does away with any imputation of a legal offence. Girls who have passed this age are considered to be capable of offering some resistance to the perpetration of the crime; and therefore, in a true charge, we should expect to find not only marks of violence about the pudendum, but also injuries of greater or less extent upon the body and limbs. It is probable that in these cases, if the charge were well founded, the hymen would be ruptured, as the intercourse is always presumed to be violent; but there might be some degree of penetration without this being a necessary result, especially if the membrane were small, or placed far up. At any rate, a girl at this age may sustain all the injury, morally and physically, which the perpetration of the crime can possibly bring down upon her, whatever may have been the degree of penetration; and for this reason, it is very properly laid down by our law, that the crime consists in the mere proof of penetration. The fact, however, is generally clearly made out by the statement of the girl. Girls of tender age are sometimes violated by boys; the amount of physical injury inflicted in such cases is less than when the assailant is an adult. In addition to other cases reported, Dr. Geoghegan, of Liverpool, communicated to me one which was the subject of a trial at the Liverpool Winter Assizes of 1862. A boy aged seventeen committed rape on two children, one aged eight years, and the other ten years; he then attempted to commit a rape on a third girl, aged eleven years. These crimes were perpetrated in about half an hour, during which time he was alone with the children. He was convicted of felony for rape on the youngest child, and sentenced to four years' penal servitude.

With respect to *marks of violence* on the person, the exact form, position, and extent of these should be noticed, also their appearance, whether recent or of old standing. A false accusation of rape may be sometimes detected by the violence being in a situation in which it is not probable that the ravisher could have produced it. When bruises are found, the presence or absence of the usual zones of color may occasionally throw light upon the time at which the alleged assault was committed (p. 263, *ante*). As these marks of violence on the person are not likely to have been produced with the concurrence of the girl, they are considered to furnish some proof of the intercourse having been against her will. But the physical appearances of rape about the genital organs may be found, whether the connection has been voluntary or involuntary. Thus rupture of the hymen, laceration of the vagina with effusion of coagula of blood, swelling and inflammation of the vulva, and stains of blood upon the person, dress, or furniture may be met with in both cases. In making an examination, the greatest care should be

taken by the practitioner to fix, at the time of examination, a probable date for the marks of injury to the genitals or other parts of the body, as it is by the aid of such observations that the truth or falsity of a charge may be sometimes clearly established.

Girls and unmarried young women are liable to *muco-purulent discharges* from the vagina, as a result of which the hymen may be destroyed. This kind of discharge arises from inflammation of the vagina (vaginitis), and it has been observed to follow an attack of scarlatina. When it exists, its real cause requires the closest scrutiny. At a more advanced age, young women are frequently subject to leucorrhœa. These cases are not likely to be mistaken for gonorrhœa; as here the female has it in her power to give some account of the circumstances, from which a medical opinion may be easily formed. It is possible, however, that a woman laboring under leucorrhœa may charge a man with the crime of rape, and affirm that this discharge had arisen from the act of the man. An inflamed and partially ulcerated (aphthous) state of the lining membrane of the vulva may apparently give support to the accusation. The discharge in leucorrhœa is of a mucous nature—that of gonorrhœa is of a purulent character—but purulent discharges may take place from the vagina as the result of intense inflammation, and quite irrespective of impure intercourse. (“Chelius’s Surgery,” by South, vol. 1, p. 160.) It would be impossible to distinguish such discharges from those of gonorrhœa; while a leucorrhœal discharge under great inflammatory action may resemble that of gonorrhœa. Such discharges commencing before, but continuing and sometimes becoming aggravated after marriage, have given rise to unfounded suspicions of infection from venereal disease imparted by the husband, and have thus led to suits of divorce. In a case reported by M. Legneau a young married woman suffered from a discharge which was pronounced by a medical man whom she consulted to be gonorrhœal. This led to an application for a divorce. A further examination by other medical practitioners, with a complete history of the symptoms from which she had suffered, justified the conclusion that she was laboring under severe leucorrhœa when she was married, and that this was followed by granular vaginitis which accounted for the muco-purulent discharge. (“Ann. d’Hyg.,” 1870, 2, 192.)

Defloration. Signs of virginity.—It will be necessary to say a few words respecting the *signs of virginity*—a subject upon which, in some medico-legal works, a great amount of poetical discussion appears to me to have been wasted. Independently of cases of rape, this question may occasionally assume a practical bearing in relation to the signs of defloration. In civil cases a medical witness may be asked whether a woman has ever had intercourse or not: and proof of the fact may be necessary in order to confirm or rebut statements made by her in evidence. The question may be not whether a woman has had a child, for this would resolve itself into a proof whether delivery had or had not taken place:—it may be limited to the probability or possibility of intercourse on her part at some antecedent period. Now, a medical jurist, when consulted in such a case, can be guided only by the presence or absence of the external signs of virginity. The hymen may be intact, but this does

not prove non-intercourse, because females have been known to become pregnant with the hymen uninjured; and an operation for a division of this membrane has been rendered necessary before delivery could take place. (Henke's "Zeitschrift der S. A.," 1843, vol. 2, p. 149.) Two instances of impregnation without rupture of the hymen are reported in the "New Orleans Medical Gazette" for June, 1858 (pp. 217, 220). The hymen in each case required to be divided to allow of the delivery of the child. Other cases are reported in the "American Jour. Med. Sciences" for April, 1859 (p. 576). Two have been recently published by Dr. Broun in Eulenberg's "Vierteljahrsschrift" for 1873, 2, p. 197, and one well-marked case by Dr. St. Clair Gray, in the "Glasgow Medical Journal" for May, 1873. A woman æt. 29 had been seven years married before this her first confinement. It was found that she had a persistent hymen of such size and form as completely to occlude the meatus except in its central part, where there was a small aperture. This had admitted of the menstrual flow and of impregnation. A crucial incision was made through it, and the woman was then delivered. In a case of pregnancy with unruptured hymen which occurred to Mr. H. Taylor, of Guildford, the membrane was dense and concave, admitting the point of one finger, and by gradual pressure two fingers. This membrane was ruptured in delivery. ("Brit. Med. Jour.," June, 1878, p. 863.)

These facts generally admit of explanation by the membrane being of abnormal structure. Thus it has been found hard, dense, fibrous, resisting and sometimes small in extent, thus only partially closing the vagina. Under opposite conditions, the persistence of this membrane might fairly lead to the inference that the female was chaste and that there had been no intercourse. In the case of *Reppingull v. Reppingull*, in which the husband sued for a divorce on the ground of adultery, the evidence showed that the wife had not allowed her husband to have intercourse with her, and the marriage had never been consummated. At the same time it was proved that she had privately visited the co-respondent; but she denied that there had been any intercourse. She was, subsequently to this, examined by Drs. Oldham, Gervis, and Barnes, and they deposed, from the state of the hymen, that she was still *virgo intacta*. On this the jury found that there had been no adultery.

The hymen may be destroyed by ulceration, as a result of inflammation of the genital organs. When the membrane has been thus destroyed by disease or other causes, or when it is congenitally absent, a medical opinion must be more or less conjectural; for one intercourse could hardly so affect the capacity of the vagina as to render the fact evident through life, and there is no other datum upon which an opinion could be based. The presence of the hymen is usually considered to be quite incompatible with the assumption that a woman has borne a child. A question of this kind incidentally arose in *Frazer v. Bagley* (Common Pleas, Feb. 1844.) It was alleged by defendant that the plaintiff, a married man, had had adulterous intercourse with a young woman, and that at an antecedent period she had left her home for the purpose of giving birth to a child privately. The late Dr. Ashwell was called upon to examine the woman, and he deposed that, in his opinion, she was a

virgin, and had never borne a child. In spite of this evidence, the jury returned a verdict for the defendant. It is quite possible, however, that abortion may take place at the early periods of pregnancy, without the necessary destruction of the hymen. (See Henke's "Zeitschrift," 1844, vol. 1, p. 259.)

M. Stolz, after remarking on the fact that women may conceive without the destruction of the hymen being necessarily involved, alleges that this membrane may still remain even after a woman has been delivered of a child.² He quotes an instance within his own knowledge in which a young woman, whose hymen was in the form of a ring or loose diaphragm open in the centre, was delivered without any alteration being produced in it. It was only destroyed at her second delivery ("Ann. d'Hyg." 1873, 2, p. 148). The peculiar form of the hymen in this case might account for its persistence. Such cases must depend upon some exceptional conditions of the membrane.

This question is of importance, not only as it may affect the reputation of a woman, but the credibility and character of a person who makes an imputation of unchastity. In 1845, a gentleman, then assistant-surgeon in the Bombay Army, was brought to a court-martial on the charge of having deliberately and falsely asserted that on several occasions he had had connection with a native woman. This was denied by the woman, and evidence was adduced to show that she had still what is commonly regarded as the main sign of virginity, namely an unruptured hymen. In consequence of this the medical officer was found guilty, and cashiered. The woman was at the time about to be married, and this rendered the investigation all the more important to her. An assistant-surgeon, who examined the girl, deposed that he found the membrane of a semilunar form, and tensely drawn across the vagina; and his evidence was corroborated by that of a midwife. The inculpated person took a double line of defence—1st, that the examination of the woman was incomplete; and 2dly, that the hymen, if present, would not justify the witnesses in saying that intercourse could not have possibly taken place. On the first point, it is unnecessary here to make a remark; but it appeared from their own admissions, that the witnesses had never before examined women with this particular object. Assuming that there was no mistake, it becomes a question whether non-intercourse could in such a case be inferred from the presence of the membrane. Fruitful intercourse, it is admitted, may take place without rupture of the hymen. Some instances of this kind were referred to at the court-martial; but such cases may be regarded as of an exceptional nature (p. 756, *ante*). The real question is, whether, unless the hymen be in an abnormal state, intercourse can possibly occur between young and active persons without a rupture of this membrane? Intercourse is not likely to be confined, under these circumstances, to a mere penetration of the vulva. The membrane in this woman is stated to have been tensely drawn across the canal, and it was not tough; it was therefore in a condition to render it most easy for rupture. In the case of an old man, or of one of weak virile power, vulval intercourse might be had without destroying the membrane; but such a case could only be decided by the special circumstances which accompanied it. The presence of an unruptured hy-

men affords a presumptive, but not an absolute proof that the woman is a virgin; and if of the ordinary size and shape, and in the ordinary situation, it shows clearly that, although attempts at intercourse may have been made, there can have been no vaginal penetration. Admitting the statements of the examiners to have been correct, it is improbable that this woman had had sexual intercourse several times, or even on one occasion; hence the imputation on her chastity was unfounded.

In the case of *Delafose v. Fortescue* (Exeter Lent Ass., 1853), which involved an action for defamation of character, the plaintiff, a married man, æt. 64, had been charged with committing adultery with a certain woman. Several witnesses for the defendant, positively swore that they had seen these persons in carnal intercourse. This was denied by the plaintiff; and, as an answer to the case, medical evidence was tendered to the effect that the woman with whom the adulterous intercourse was alleged to have taken place, had been examined and the hymen was found intact. In cross-examination this was admitted not to be a conclusive criterion of virginity. A verdict was returned for the defendant. The form and situation of the hymen in this case were not described; but it is to be presumed that these were not such as to constitute a physical bar to intercourse, or this would have been stated by the medical witness. Hence the persistence of the membrane was not considered to disprove the allegations of eye-witnesses. A somewhat similar case (*Howes v. Barber*) was tried in the Common Pleas in June, 1865. Defendant alleged that he had seen plaintiff, as he believed, in intercourse with an unmarried lady. This was denied by plaintiff and the lady, and to support this denial medical evidence was called to show that there had been no intercourse. Drs. Oldham and Barnes examined the lady, and deposed that the hymen was entire, and that she was *virgo intacta*. In Scotland this kind of medical evidence is not admissible. I am indebted to Mr. Trayner, a member of the Scotch Bar, for the subjoined case, in which a wife sued the husband for divorce, on the ground, *inter alia*, that he had committed adultery with C. In defence, the defendant denied the adultery, and adduced C. as a witness, who swore that such connection had never taken place. She also swore that she had submitted to an *inspectio corporis* by Sir James Simpson. The defendant then proposed to examine this gentleman, that he might speak to the result of his examination. He argued that this was the best evidence that he could adduce in support of his innocence, as, if the girl was still a virgin, the adultery alleged could not have been committed. The court refused to admit the evidence, on the ground that it was merely in the form of an opinion from the learned professor; that other medical men might differ from him, even from the same observations; and that, as the court could not compel C. to submit to another examination, the proposed evidence must be considered *ex parte* and inadmissible. (Sessions' Cases, Edinburgh, Feb. 11, 1860.) In *Hunt v. Hunt*, a verdict was obtained at common law against the alleged paramour in a case of adultery, and the damages were assessed at 50*l*. It was subsequently proved that the lady was *virgo intacta*! But so long as there are facts which show that women have actually conceived with the hymen still in its normal state, it is inconsistent to apply the terms "virgo intacta" to women merely because

this membrane is entire. A woman may assuredly have an unruptured hymen, and yet not be a *virgo intacta*. This can be decided only by the special circumstances proved in each case. Such *virgines intactæ* have frequently required the assistance of accoucheurs, and in due time have been delivered of children! (p. 756, *ante*.)

A question of this kind arose in *Reg. v. Harmer* (C. C. C., June, 1872). Prisoner was indicted for perjury. He was a waiter at a tavern, and being called as a witness in a divorce suit, swore that he had seen the parties in adulterous intercourse on more than one occasion. The lady with whom the adultery was alleged to have been committed, denied this on oath, and Dr. R. Lee and another medical expert gave evidence that they had examined this lady, and found her to be a *virgo intacta*, no doubt from the persistence of the hymen. The Recorder, in summing up, told the jury that this evidence was of the highest importance, and it was for them to consider whether it was sufficient to satisfy them of the guilt of the prisoner. He was found guilty and sentenced to imprisonment.

In reference to these cases of persistent hymen, it is a question whether medical men, in forming an opinion, have sufficiently considered the variable structure of the membrane. It has been found to consist in some instances of tough fibrous or fibro-elastic tissue, and in such cases, it might remain unruptured in married life as well as in cases of actual rape. Dr. St. Clair Gray has properly directed the attention of the profession to this subject. What may be true of a thin semilunar membrane placed in its normal position, will not be applicable to those instances in which its structure is abnormally firm, hard, and resisting. In the "Glasgow Medical Journal" for May, 1873, this gentleman has published several cases which show that the hymen may be persistent for years in married women, in spite of attempts at intercourse. In one case, a woman, æt. 43, who had been married twenty-four years, the hymen was found by him entire—closing the meatus with the exception of a small aperture which allowed of the menstrual flow. In a second case, a woman, æt. 30, had been married ten years, and was childless. On examination, the hymen was found entire, and its persistence was evidently due to the presence in the tissue, of fibrous or fibro-elastic bands, which rendered the structure as a whole very resilient. In this case, the hymen was forcibly ruptured by a speculum. In three cases of women who had been living in habits of prostitution for seven, eight, and eleven years respectively—the hymen was found unruptured. Its structure in these instances also accounted for its persistence. In all it was firm and elastic, and in one of them it had almost a cartilaginous hardness.

From cases already quoted, these facts, it will be seen, acquire some medico-legal importance. Intercourse may have taken place although the hymen is found entire. In spite of its presence, a woman may have been guilty of a want of chastity. Even rape might be attempted, and legally perpetrated in adult women without necessarily rupturing this membrane. Married women have not always been conscious of this

When a charge of rape is made by a prostitute, it is justly received with suspicion, and the case is narrowly scrutinized. Something more than medical evidence would be required to establish a charge under these circumstances. The question turns here, as in all cases of rape upon adult women, on the fact of *consent* having been previously given or not. This is the point at which the greater number of these cases of alleged rape break down; and it need hardly be observed, that this question has no relation to the duties of a medical witness:—all that he can do is to establish, occasionally, whether or not sexual intercourse has been had with or without some violence. It is obvious that there may be marks of violence about the pudendum, or on the person, and yet the conduct of the woman may have been such as to imply consent on her part: we must not suppose that medical proof of intercourse is tantamount to legal proof of rape.

[While it is no defence that a woman was a common strumpet, or even that she was the defendant's mistress, the question of prior chastity is always a material one to be considered by the medical examiner, since unchastity can be shown by the defendant, not as an excuse or justification, but as a fact throwing much light on the subject. (Wharton & Stillé, 2d ed., p. 466.)

In England, and in many of the United States, general evidence of reputation may be shown, but not particular acts of unchastity. *Ib. McCombs v. State*, 8 Ohio (N. S.) 643; *People v. Jackson*, 3 Parker, C. R. (N. Y.) 391.

It has been held, however, that it is competent to inquire of the prosecutrix, on cross-examination, as to particular acts before and after, at specified times and places, with specified men. *State v. Johnson*, 2 Wms. (Vermont), 512. In California, where the prosecutrix was the only witness, it was held that evidence that she had committed acts of lewdness with other men is admissible, and that it is immaterial by whom these acts are proved, and that the prosecutrix need not be questioned about them. *People v. Benson*, 6 Cal. 221.—P.]

Possibility of perpetrating rape on adult women.—Some medical jurists have argued that a rape cannot be perpetrated on an adult woman of good health and vigor; and they have treated all accusations made under these circumstances as false. Whether, on any criminal charge, a rape has been committed or not, is of course a question of fact for a jury, and not for a medical witness. The fact of the crime having been actually perpetrated can be determined only from the evidence of the prosecutrix and of other witnesses: still a medical man may be able to point out to the court circumstances which might otherwise escape notice. Setting aside the cases of infants, idiots, lunatics, and weak and delicate or aged women, it does not appear probable that intercourse could be accomplished against the consent of a healthy adult, except under the following conditions:—

1. When narcotics or intoxicating liquids have been administered to her, either by the prisoner or through his collusion. It matters not, in a case of this kind, whether the narcotics have been given merely for the purpose of exciting the female, or with the deliberate intention of having intercourse with her while she was intoxicated—the prisoner is equally

guilty. (See *Reg. v. Camplin*, "Law Times," June 28, 1845; also "Med. Gaz.," vol. 36, p. 443.) The nature of the substance whereby insensibility is produced is, of course, unimportant. Thus the vapors of ether and chloroform have been criminally used in attempts at rape. In a case which occurred in France, a dentist was convicted of a rape upon a woman, to whom he had administered the vapor of ether. The prosecutrix was not perfectly unconscious, but she was rendered wholly unable to offer any resistance. ("Med. Gaz.," vol. 40, p. 865.) A dentist was recently convicted of rape under somewhat similar circumstances in the United States, but it was thought that the woman had made the charge under some hallucination or delusion. In *Reg. v. Snarey* (Winchester Lent Ass., 1859), there was a clear attempt at fraud. The prosecutrix asserted that she was *instantly* rendered insensible by the prisoner forcibly applying a handkerchief to her face, and she accused him of having committed a rape on her. The charge was disproved by a distinct alibi, as well as by the improbability of all the circumstances.

When the state of unconsciousness arises from natural infirmity, as in idiocy, or insanity, carnal intercourse with a woman is regarded as rape. (*Reg. v. Ryan*, Cent. Crim. Court, September, 1846.) The woman was in this case an idiot, and it was proved that her habits were not loose or indecent. Platt, B., held that if she was in a state of unconsciousness at the time the connection took place, whether it was produced by any act of the prisoner or by any act of her own (?), any one having intercourse with her would be guilty of rape. The prisoner was convicted. In a more recent case (*Reg. v. Fletcher*, Crown Cases Reserved, May, 1866), in which the prisoner had been convicted of rape on an idiot, the Chief Baron delivered the judgment of the court to the following effect: This was an indictment for a rape upon the prosecutrix, who was an idiot. The prisoner had admitted the intercourse, but added that it was with consent. The point had been reserved for the purpose of ascertaining whether this was such an offence that the prisoner could be convicted of it. No doubt there was the clearest evidence that an offence had been committed, but, it was said, with the consent of the prosecutrix. The Crown had given no evidence that the act was done against her will, which was the allegation in the indictment. The court considered that, as no such evidence was given, the prisoner ought not to have been convicted. Conviction quashed. It would seem, therefore, that an idiot may, under certain circumstances, give consent which will exonerate the accused.

In *Reg. v. White* (Northampton Winter Ass., 1856), the learned judge, in charging the jury, stated that some doubts were entertained whether the crime of rape could be committed (in law) on the person of a woman who had rendered herself perfectly insensible by drink, so as to be unable to make any resistance; he thought it could not be alleged as an excuse for the man. The question was not reserved, as the prisoner was acquitted of rape, and found guilty of an indecent assault.

It may be a question whether a man can have intercourse with a woman without her knowledge, while thus in a state of *unconsciousness from natural sleep*. Casper met with a solitary case in which a girl aged 16

accused a man of having had intercourse with her while she was sleeping in her bed, of which she was not conscious until he was in the act of withdrawing from her. On her own statement, she was *virgo intacta* up to the date of this occurrence. Upon the facts of the case, Casper came to the conclusion that, if her statement was true, the man could not have had intercourse with her without causing pain, and rousing her to a consciousness of her position. The hymen was not destroyed, but presented lacerations in two places. This and other facts showed that there had been intercourse, but did not prove that this had taken place without the consciousness of the woman. ("Klinische Novellen," 1863, p. 31.) A man was charged with rape before a police magistrate, and the prosecutrix swore that he had effected his purpose during her sleep. The bare possibility of the offence being perpetrated under these circumstances cannot be denied; but this admission could only apply to a case in which the woman had been accustomed to sexual intercourse, and in which the sleep was preternatural or lethargic. In this instance the woman was a prostitute, and the charge improbable. A respectable married woman, who had had children, the wife of an innkeeper, threw herself on her bed with her clothes on, late one evening, and fell fast asleep. She was first awakened by finding a man upon her body, in the act of withdrawing from her. This man, *William McEwan*, a servant in the house, was given into custody on a charge of rape. In the first instance he did not deny the act, and there was no reason to believe that the prosecutrix was aware of the prisoner's conduct until the crime was completed, and she was awakened in the manner described—apparently by the weight of the prisoner's body. The prisoner was convicted, and sentenced to ten years' penal servitude. ("Edin. Month. Jour.," December, 1862, p. 570.) A case which may serve to throw a little light upon this question occurred to Casper. ("Gerichtliche Medicin," vol. 2, p. 574.) A married woman alleged that a man had had intercourse with her while in bed, and when she was asleep. In her deposition, however, she admitted she was conscious that some one was lying upon her, and that she asked who it was: showing, as Casper remarks, that she had a knowledge of what was going on, and some *doubt* whether the person was her husband!

In reference to this question whether it is possible to commit a rape upon a woman while asleep, a majority of the Scotch judges decided, in the case of *Sweenie* (Irvine's "Justiciary Reports," vol. 3, p. 109), that the feloniously having connection with a woman while asleep, was not indictable under the name of rape, inasmuch as, apart from the force implied in the act of connection, there was no force used to overcome the will of the woman. But they held, however improbable it might be, it was quite possible that a man might have connection with a woman while asleep. ("Edin. Month. Jour.," December, 1862, p. 570.)

[We are indebted, for a case in point, to our friend Dr. D. F. Lewis, formerly of London, and now librarian to the Pennsylvania Hospital of Philadelphia. While practising in London, 1853, he was called to attend a young woman, previously well known to him as of excellent character, and found her in a violent hysterical paroxysm, brought on by the discovery that she had been violated, during sleep, by her accepted admirer.

She had returned to her mother's home with him, from a long walk, very much fatigued, and after having drank a glass of ale, had sunk into a profound slumber, during which the act had been perpetrated without the slightest evidence of consciousness on her part. This was admitted by her companion; and her prompt discovery of the wrong, and immediate alarm and agitation, as well as her known liability to unusually heavy sleep, fully established the truth of her assertion. The usual physical signs of recent defloration were presented on her person.—H.]

The condition of the so-called *magnetic* or unnatural sleep has given rise to a question connected with the alleged perpetration of rape. A girl (aged 18) consulted a therapeutic magnetizer as to her health. She visited him daily for some days. Four and a half months afterwards she discovered that she was pregnant, and made a complaint to the authorities against the magnetizer. They directed a physician and surgeon to determine the date of her pregnancy, and whether the complainant might have then been violated and rendered pregnant contrary to her will, *i. e.*, whether her volition could have been completely or partially annihilated by magnetism. The medical inspectors were satisfied that the pregnancy did not extend further back than four and a half months; and founding their opinion on M. Husson's report, made to the Academy in 1831, concluded that as a person in magnetic sleep is insensible to every kind of torture, sexual intercourse might then take place with a young woman without the participation of her will, without consciousness of the act, and consequently without the power to resist the act consummated on her. This opinion was confirmed by that of Devergie. ("Gazette Médical de Paris," and "Edin. Month. Journ.," December, 1860, p. 566.) There is another view of this case which does not seem to have occurred to the French medical experts, namely: "*Non omnes dormiunt quæ clausos habent oculos.*" [Where the testimony was to the effect that the person alleged to be ravished was awakened by the act of the prisoner, to which she made no resistance or outcry, when there was another person in the room who could have heard her, it was held not to be a case of rape. *Pollard v. The State*, 2 Clarke (Iowa), 567.—P.]

A trial for rape took place at Rouen Assizes (Aug. 1878), in which a new theory was suggested by certain French physicians. A girl, æt. 20, consulted a dentist (Lévy), who placed her in his professional chair and brought her to a horizontal position. He was charged with committing a rape. There was no doubt that intercourse had taken place, and the dentist admitted it,—but that it was with the consent of the girl. She was subsequently delivered of a seven months' child, corresponding to this date. Her statement was that the accused passed something over her gums which gave a sensation of burning. In a few minutes she lost all consciousness, and when she awoke she felt pain in her sexual organs, and there were marks of blood on her thighs. No examination was made for two months. Four physicians who gave evidence as experts agreed that no anæsthetic had been used, but that the girl, being of an excitable temperament, had fallen at the time into an hysterical sleep, in which she would not be conscious of the act. One of them thought it might have been owing to a hypnotism induced by the dentist. It seems that during

the time the mother was in the room with her, and although the girl uttered a cry she did not interfere, not suspecting anything wrong! The dentist was convicted and sentenced to ten years' imprisonment. 'This theory of *hysterical sleep* coming on suddenly, and being so profound as to destroy all consciousness of a first intercourse, is not supported by any experience. It is far more probable that the woman retained a sufficient amount of consciousness to resist the assailant, or that, if partially stupefied from any cause, she would have been roused by the act. For an analysis of the evidence in this remarkable case by M. Brouardel, see "Ann. d'Hyg.," 1879, 1, p. 39.

2. A rape may be committed on an adult woman if she falls into a state of syncope, or is rendered powerless by terror and exhaustion from long struggling with her assailant. The late Lord Justice Clerk Hope suggested to me that, in his opinion, too great distrust is commonly shown in reference to the amount of resistance offered by women of undoubted character. Inability to resist from terror, or from an overpowering feeling of helplessness, as well as horror at her situation, may lead a woman to succumb to the force of a ravisher, without offering that degree of resistance which is generally expected from a woman so situated. As a result of long experience, he thought that injustice was often done to respectable women by acting on the opinion that resistance was not continued long enough.

3. When several are combined against the woman, in which case we may expect to find some marks of violence on her person, if not on the genital organs.

4. A woman may yield to a ravisher, under threats of death or duress: in this case her consent does not excuse the crime, but this is rather a legal than a medical question. An aged woman can scarcely be expected to resist a strong man. Dr. Chevers mentions a case in which a man was convicted of rape and aggravated assault on a woman of *seventy* years of age.

Rape may be perpetrated on a female at any age. Rapes on female infants and children are frequent. Boys have been on several occasions convicted of rape on young females. At the Lewes Summer Ass., 1874, a boy of 14 was convicted of a rape on a girl under 12. The boy confessed the circumstances with great frankness and apparent unconsciousness of the nature and gravity of the offence. The learned Judge (Bramwell, B.) sentenced him to seven years' penal servitude, intimating, however, that there would be a special report on his case sent to the Home Office.

Loss of physical evidence.—It is necessary to observe, in relation to the examination of married women, that the indications of rape on the genitals, however well marked they may have been in the first instance, either soon disappear or become obscure, especially in those who have been already habituated to sexual intercourse. After two, three, or four days, unless there has been an unusual degree of violence, no traces of crime may be found about the genital organs. In the case of an adult married woman examined by Dr. Mayne, the appearance of injury which he discovered in and about the vagina, had begun to heal in less than forty-eight hours; but in a case examined by Casper, on the *ninth day* the lining-membrane of the vagina was still reddened, and the parts were

still painful. In this case the hymen had been completely torn through. ("Gerichtliche Medicin," vol. 2, p. 157.) In married women, or in those accustomed to sexual intercourse, no inference can be drawn from a dilated state of the vagina. In unmarried woman, and in children when there has been much violence, these marks may persist and be apparent for a week or longer. If there has been great laceration of the sexual organs, then certain appearances in the form of cicatrices may remain; but in all cases great caution should be observed in giving an opinion of rape having been perpetrated, from an examination made two or three weeks after the alleged commission of the offence. Marks of violence on the person can never establish a rape; they merely indicate, *cæteris paribus*, that the crime may have been attempted.

Pregnancy following rape.—It has been a question, whether when intercourse has taken place against the will of a woman, *i. e.* in the perpetration of rape by violence, pregnancy could possibly follow. It was at one time thought that the will of a woman was always necessary to the act of impregnation, and therefore if she became pregnant, she must have consented to the act, and that the charge of rape was unfounded. Such a defence would not be admitted as an answer to a charge of rape or to show, under any circumstances, that intercourse had been had with consent. Conception, it is well known, does not depend on the consciousness or volition of a woman. If the state of the uterine organs be at the time in a condition favorable to impregnation, this may take place as readily as if the intercourse had been voluntary: even penetration to the vagina is not absolutely necessary for impregnation. (See case by Dr. Oldham, "Med. Gaz.," vol. 44, p. 48.) In a case communicated to me by the late Mr. Carrington, a woman became pregnant after a rape committed on her by a man who subsequently married her: the date of intercourse was thereby accurately fixed, and a child was born after 263 days' gestation. (See also paper by M. Stolz, "Ann. d'Hyg.," 1873, vol. 2, p. 146.)

It has been supposed, that in cases of pregnancy following rape, in spite of resistance at first, a woman may in the end have voluntarily joined in the act. I know of no ground for adopting this theory: the general opinion is, that conception may occur, and is neither accelerated nor prevented by the volition of the sexes. Many women in married life who anxiously wish for children have none, and *vice versâ*; and physical impediments do not suffice in all cases to explain these facts. Women are reported to have conceived during the states of asphyxia, intoxication, or narcotism. Dr. Ryan mentions a case in which a young woman became unconsciously pregnant from intercourse had with her by a man while in a state of intoxication, and in which it was clearly impossible that her volition could have taken any share. ("Med. Juris.," p. 245.) In married life there is no doubt that women frequently become pregnant against their will, and in a great number of cases without any consciousness of their condition until pregnancy is far advanced. Those who affirm that without the active will of the woman there can be no conception, must deny the existence of cases of impregnation in a state of unconsciousness (p. 549, *ante*); but the facts are too strong and too numerous to be met with a simple denial. A medical jurist, therefore, who relied

upon pregnancy following alleged rape, as a proof of *consent* on the part of the woman, and who would infer from this result that the intercourse must have been voluntary on her part, would inflict great injustice by such an opinion. The extrusion of an ovum does not depend on the will of a woman, but is a periodical condition; the action of the spermatozoa on this ovum is as much removed from the will of the woman, as it is from that of the man.

This subject would have hardly required so much notice, but for the fact that in some recent trials it has been put forward with a view to discredit the evidence of a woman, where pregnancy has followed intercourse in a state of alleged unconsciousness. Any statement of this kind certainly requires a close examination, because, generally, there is a strong motive for falsehood on the part of the woman. In the case of *Bromwich v. Waters* (pp. 683, 688, *ante*), the young woman Whalley had had a child, but stated that she had not been conscious of any intercourse. The fact that she had borne a child did not prove that her statement was false, although a suggestion to this effect was made. We may fairly doubt whether a woman could have intercourse unconsciously, but because impregnation follows, this is no proof that she is guilty of falsehood or perjury.

Microscopical evidence.—As part of the medical evidence in cases of rape, it may be necessary to examine *spots* or *stains* on the linen of the prosecutrix and the accused. Cases of rape are, however, commonly tried in this country without reference to this species of evidence; and it is not easy to perceive how this can be necessary to the proof of the crime in the living, when the present law of England demands only proof of penetration, and not of *emission*. (24 & 25 Vict., c. 100, s. 63.) Thus, a rape may be legally completed without reference to emission; and, medically speaking, it appears quite possible that there might be marks of emission without any penetration, as in a protracted resistance on the part of a woman. Admitting that certain stains of this description are found on the clothes of an accused person—are these to be taken as furnishing undeniable proof of the legal completion of rape by penetration? It appears to me that without corroborative evidence from the state of the female organs they cannot be so taken; and therefore the affirmative evidence from the microscope, under these circumstances, is as liable to lead to error as that which is purely negative. The fact that spermatic stains are found on the linen of the prosecutrix, may however become occasionally of great importance in charges of assault with intent. (*Reg. v. Hamilton*, Edinburgh, Nov. 27, 1843.)

Examination of stains.—There are no *chemical* tests on which we can safely rely for the detection of spermatic stains. The appearance produced by a dried spermatic stain on linen or cotton is like that produced by a diluted solution of albumen. The fibre of the stuff is stiffened, and the stain, particularly at the margin, has a slightly translucent appearance, as if the stuff had been wetted by diluted gum or albumen, but without any shining lustre. In the dry state the stains present no well-marked color or odor. Slips of the stained linen, when soaked in a small quantity of distilled water, yield an opaque muco-albuminous liquid, slightly alkaline. It was long since noticed by Orfila that this

liquid, unlike a solution of albumen, was rendered rather strongly yellow by diluted nitric acid. By the action of warm water, the stained linen even although it may have been kept dry for a considerable period, has been observed to evolve the peculiar faint odor of the spermatic secretion.

The stained linen, or a part of it, should be cut into small pieces, taking care that it is not roughly handled. These should be placed in a small porcelain capsule or watch-glass, with a sufficiency of distilled water (eight or ten drops) to soak it thoroughly, and to allow the fibre of the stuff to become quite penetrated by the water. It is advisable not to move the stuff or agitate the liquid, but to allow it to be quietly imbibed. The watch-glass or capsule should be covered so as to prevent evaporation and to keep out foreign matters. After half an hour the fibres may be turned and allowed to macerate for some time longer. The stained linen may then be removed, and the soaked fibres of the stuff gently pressed on several glass sides, already cleaned and prepared for the purpose. The liquid thus obtained by pressing the stained linen is slightly opaline. It is found that this opalescence is removed by the addition of a small quantity of ammonia or acetic acid; these liquids do not affect the forms of the spermatozoa. The stains are more completely dissolved by water which is slightly tepid. Care must be taken not to use more water than is actually required to moisten the stained stuff and to allow a small portion to be pressed out of it.

The liquid on the slide may be then covered with microscopic glass, and examined in a good light under a power varying from 350 to 500

diameters. The dead spermatozoa may then be seen as in the annexed engraving. (Fig. 69.) They have flattened ovoid heads, with long tapering tails which are from nine to twelve times the length of the head. They are usually associated with granular bodies and epithelial scales. Fibres of cotton, linen, or woollen may be mixed with them, and there may be also pus, mucus, or blood-globules. Their form is so peculiar that when once well seen and examined, they cannot be confounded with any other substance, vegetable or animal, nor with ordinary care can any vegetable fibres be mistaken for them, al-

Spermatozoa magnified 450 diameters.

though these may be mistaken for their tails or filaments. Particular notice should be taken of any hairs or fibres found in such stains. They may be human or animal hairs, and the fibres may by their nature, form and color, be connected with some article of dress, worn by the woman or the person accused of rape. Some remarkable cases in which evidence was furnished by these stains and substances associated with them, will be found in the Russian Official Report, "Anleitung zur Untersuchung verdächtiger Flecke für Aerzte und Juristen. St. Petersburg, 1871."

The spermatozoa appear to retain life long after the death of the body. Professor Hofmann, of Vienna, states that he has observed the active movements of these bodies from eighty to one hundred hours after death.

Some observers have advised that the expressed liquid obtained from spermatic stains should be allowed to dry spontaneously on the slide and then be examined in the dry state. When humid, the bodies, and especially the tails, are so transparent that the whole spermatozoon may escape observation. One part only may come into focus at a time. They become opaque by drying and may be seen in darker lines, sometimes in their whole length. (See Casper's "Vierteljahrs.," 1858, vol. 1, p. 140, and 1866, vol. 2, p. 349.) M. Roussin recommends the addition of a solution of iodine in iodide of potassium to the liquid submitted to examination. He has found that it brings out the entire form of the spermatozoon of a deep yellow color, and thus makes a distinction between it and other fibrous substances. ("Ann. d'Hyg.," 1867, vol. 1, p. 154.)

As it has been elsewhere stated, the spermatozoa, although peculiar to the seminal fluid, are not found in the very young, the very old, or in those who are laboring under long-standing disease of the testicles (p. 723). Even in the cases of healthy married men, who have had children, spermatozoa are not always found in the spermatic secretion; their presence, size, and number are subject to great uncertainty. Exhaustion from frequent intercourse, or constitutional causes without actual bodily disease, appear to influence their production. There are also various other conditions in which they are not found; these have been fully examined by Casper ("Gerichtliche Medicin," vol. 2, p. 141). Hence the discovery of spermatozoa in stains on articles of clothing demonstrates that they have been produced by the spermatic liquid; but their non-discovery, under these circumstances, does not prove that the stains have not been caused by this liquid. Dr. Koblanek's conclusions on this subject are therefore not borne out by facts.

The detection of dead or motionless spermatozoa in stains, may be made at long periods after emission, when the fluid has been allowed to dry. (Fig. 70.) In three cases, at intervals of from one week to seven weeks after the perpetration of the crime, Casper was enabled to demonstrate the presence of spermatozoa on articles of clothing, and thus to furnish strong corroborative evidence. (Op. cit., vol. 2, p. 161.) Dr. Koblanek made experiments on this subject, in reference to different periods of time; he found these bodies distinctly, after twelve months. The discovery of one distinct and entire body is quite sufficient to justify a medical opinion of the spermatic nature of the stain. M. Bayard states that he has been able to detect spermatozoa in stains after six years ("Man. Prat. de Méd. Lég.," p. 277); and M. Roussin, after the long period of eighteen years! ("Ann. d'Hyg.," 1867, vol. 1, p. 152.)

Fig. 70.

Spermatozoa in stains after two years (Gonsee), magnified 800 diameters.

A medical witness must be prepared to consider the precise value of evidence furnished by the microscope, in the examination of stains on the dress of a man accused of rape. A shirt may present stains of blood, urine, mucus, or gonorrhœal discharge, some of which, but for the microscope, might be mistaken for spermatic stains. Admitting that by the process above described, the microscope enables an examiner to affirm that the stains have really been caused by the spermatic secretion, this does not prove that a rape has been committed, or even that intercourse has been necessarily had with a woman. Such stains may arise from spontaneous natural discharge, or from disease (spermatorrhœa), and therefore in themselves they afford no proof of intercourse. If from other circumstances in the case, it should be clearly and satisfactorily proved that there has been intercourse, then the presence of blood mixed with the spermatic stains might, in certain cases, justify an opinion that violence had been used. The discovery of spermatic stains on the dress of a woman, furnishes stronger evidence of intercourse, attempted or perpetrated, than their discovery on the dress of a man; but admitting that intercourse is thus proved, it may still have taken place with the consent of the woman. These stains, when found on the clothing of girls and infants, afford a strong corroborative proof of the perpetration of the crime.

Microscopical evidence from the woman.—It may become necessary to determine, in reference to a woman, whether intercourse has or has not recently taken place. All observers agree that, within a certain period after connection, the fact may be established by an examination of the vaginal mucus. A small quantity of this mucus placed upon glass, and diluted with water, will be found to contain spermatozoa, if the suspicion be correct. In addition to other characters, it may be remarked that the living spermatozoa move for many hours out of the body when kept at a temperature of 98°, and they even retain their rapid motions when the spermatic liquid is mixed with water; but these motions cease immediately on the addition of urine or chemical re-agents. According to Müller, the spermatozoa may retain vitality (or free motion) in the body of a woman for the period of seven or eight days, and even longer. M. Bayard states that he has thus detected them in the vaginal mucus of females not subject to morbid discharges, at various intervals up to three days after intercourse (op. cit., p. 277); and Donné found them under similar circumstances in a woman who had been admitted into the hospital the day before (op. cit., p. 305). This evidence may become of value in a charge of rape, but it may be easily destroyed by the presence of leucorrhœa: and it is open to an objection, that in certain morbid states of the vaginal mucus of the human female, there is found in it a microscopic animalcule, called by Donné, the *Trichomonas vaginæ*; but this has a much larger body and a shorter tail than the spermatozoon. Other substances may be sometimes found in the vaginal mucus; see case by Dr. Lender (Horn's "Vierteljahrsschrift," April, 1865, p. 355).

Marks of blood on clothing.—Marks of blood upon the linen can, of course, furnish no evidence unless taken with other circumstances. The linen may be intentionally spotted or stained with blood for the purpose of giving apparent support to a false accusation. Dr. Bayard met with

a case of this kind, in which a woman charged a youth with having committed a rape upon her infant child. On examination, the sexual organs were found uninjured; and on inspecting the marks of blood on the clothes of the child, it was observed that the stains had been produced on the *outside* of the stuff, and bore the appearance of smearing; the whole fibre had not even been completely penetrated by the liquid. The falsehood of the charge was thus established. ("Ann. d'Hyg.," 1847, vol. 2, p. 219.) A case involving a false charge of rape was tried at the Glasgow Autumn Circuit, in 1859. One of the witnesses, an accomplice, proved that she had purchased some blood and handed it to the woman who made the charge, and she saw her smear it over her person and on some sheets on which it was alleged the rape was perpetrated. The woman (*Boyle*) and her husband, who made this false charge, were convicted of conspiracy.

It may be a question whether marks of blood on the linen of a prosecutrix were caused by effusion as a result of *violence*, or by the *menstrual fluid*. In its normal state, this fluid is said to contain no fibrin; but in respect to the presence of red corpuscles and of serum, it resembles blood. That fibrin is, however, frequently present, and in large quantity is obvious from its being occasionally discharged in a clotted state: hence the discovery of fibrin in a stain would by no means necessarily imply that the blood was not derived from the menstrual fluid. Supposing the blood-stain to have been caused by imbibition from another article of dress already stained, the secondary stain would be free from fibrin, which would remain in the stuff originally wetted. A man might thus wrongly pronounce this secondary stain to be due to menstrual blood. Even the presence of epithelial scales and mucus would not prove the stain to be menstrual, unless it could be shown that the mucus was actually effused with the blood which caused the stain. The epithelial scales naturally found in vaginal mucus are flat nucleated cells, oval, round, or polygonal in shape, and varying in size. They are spread over the mucous membrane not only of the vagina, but of the mouth, pharynx, œsophagus (gullet), conjunctiva, and the serous and synovial membranes. ("Kirkes' Physiology," p. 304.) There must be great caution in relying upon this microscopical evidence.

It may be right to state, for the information of medical practitioners who have hitherto thought that they could easily distinguish menstrual blood, and swear to it on charges of rape, that, a few years since, the French Academy of Medicine appointed as a committee, MM. Adelon, Moreau, and Le Canu, to examine this question in the most comprehensive manner. These gentlemen reported that, in the present state of science, there is no certain method by which menstrual blood can be distinguished from that effused from the bloodvessels, in a case of child-murder or abortion. ("Ann. d'Hyg.," 1846, vol. 1, p. 181; see *ante*, pp. 302, 593.)

Evidence of violation in the dead.—The body of a child or woman is found dead, and a medical witness may be required to determine whether her person has or has not been violated before death. There is here some difficulty because there will be no statement from the prosecutrix herself. The witness can seldom do more than express a conjectural

opinion, from the discovery of marks of violence on the person and about the genital organs. Even if spermatozoa were detected in the liquid mucus of the vagina, or on the dress of a woman, this would merely prove that there had been intercourse; whether it had been violent or not, or against the will of the woman, would depend on the circumstantial evidence. In a case of alleged murder tried at Edinburgh some years ago, the first point to be determined in examining the dead body was, whether a rape had or had not been committed. The examination of the stains on the dress was conclusive, when taken in conjunction with the other evidence. The jury convicted the man of a rape, but acquitted him of the murder. For another case in which evidence was obtained on the examination of a dead body, see Casper's "*Klinische Novellen*," p. 17.

Rape by females on males.—So far as I can ascertain, this crime is unknown to the English law. Several cases of this kind have, however, come before the French Criminal Courts. In 1845, a female, aged eighteen, was charged with having been guilty of an act of indecency, with violence, on the person of Xavier T., a boy under the age of fifteen years. She was found guilty, and condemned to ten years' imprisonment. In another case, which occurred in 1842, a girl, aged eighteen, was charged with rape on two children—the one eleven, and the other thirteen years of age. It appeared in evidence that the accused enticed the two boys into a field, and there had forcible connection with them. This female was proved to have had a preternatural contraction of the vagina, which prevented intercourse with adult males. She was found to be laboring under syphilitic disease, and the proof of her offence was completed by the disease having been communicated to the two boys. She was condemned by the Court of Assizes of the Seine to fifteen years' hard labor at the galleys. ("*Ann. d'Hyg.*," 1847, vol. 1, p. 463.) Casper describes cases of this description which have fallen under his observation. ("*Handbuch der Gerichtlichen Medicin*," vol. 2, p. 129; and "*Klinische Novellen*," 1863, p. 15.) By the penal code of France, it is a crime in either sex to attempt intercourse with the other, whether with or without violence, when the child is under eleven years of age. That this offence is perpetrated in England cannot be doubted. It is by no means unusual to find in the wards of hospitals, mere boys affected with the venereal disease. In some instances this may be due to precocious puberty; but, in others, it can only be ascribed to that unnatural connection of adult females with male children which is punished as a crime in the other sex. The only accessible medical proof would consist in the transmission of gonorrhœa or syphilis from the woman to the child.

UNNATURAL OFFENCES.

Pederastia. Sodomy.—This crime is defined to be the unnatural connection of a man with mankind, or with an animal. The evidence required to establish this crime is the same as in rape, and therefore penetration alone is sufficient to constitute it. There are, however, two exceptions: 1st, it is not necessary to prove the offence to have been

committed against the consent of the person upon whom it was perpetrated ; and 2dly, both agent and patient (if consenting) are equally guilty ; but the guilty associate is a competent witness. In one case (*Rex v. Wiseman*), a man was indicted for having committed this offence with a woman, and a majority of the judges held that this was within the statute. Unless the person is in a state of insensibility, it is not possible to conceive that this offence should be perpetrated on an adult of either sex against his or her will ; the slightest resistance would suffice to prevent its perpetration. In August, 1849, a question on this point was referred to me from Kingston, Jamaica. A man was convicted, and sentenced to transportation for life, for the crime of sodomy, alleged to have been committed upon the complaining party while he was asleep. The only evidence against him was the statement of the complainant. The opinion given was in conformity with that of Dr. J. Ferguson, who referred the case to me, namely, that the perpetration of the act during a state of natural sleep was contrary to all probability. The remarks already made in reference to rape during sleep may be applied with greater force to acts of this nature (p. 763, *ante*). If this crime is committed on a boy under fourteen years, it is felony in the agent only ; and the same, it appears, as to a girl under twelve. ("Archbold," p. 409.) The act must be in the part where it is usually committed in the victim or associate of the crime.

Sodomy is commonly understood to signify unnatural intercourse between man and man, while bestiality implies unnatural intercourse with animals. Continental medical jurists have invented a new term, *Pederastia* (*παιδὸς ἐραστὴς*, pueri amator), comprising those cases, not unfrequent, in which boys at about the age of puberty are made the victims of the depraved passions of a certain class of men ; but this term is not applicable to the crime committed by and between adults. The medical aspects of this subject have been very fully examined by the late M. Tardieu, "Ann. d'Hyg.," 1857, 2, 133, 397, and 1858, 1, 137, 152 ; also by M. Toulmouche, "Ann. d'Hyg.," 1868, 2, 121 ; and by Dr. Louis Penard, "Ann. d'Hyg.," 1860, 2, 367. The symptoms indicative of this unnatural intercourse both in agent and patient are very fully described by these writers. Casper has also dealt with this crime and the medical evidence required to prove it. ("Gerichtliche Medicin," vol. 2, p. 176.) (See also a paper on the signs of pederastia by M. Masbrenier ("Ann. d'Hyg.," 1879, 1, 254).)

The facts are commonly sufficiently proved without medical evidence, except in the cases of young persons, when marks of physical violence will in general be sufficiently apparent. In some instances, proof of the perpetration of the crime may be obtained by resorting to microscopical evidence. (See *Donné*, *op. cit.*, p. 305.) Stains upon the linen of young persons may thus furnish evidence that the crime has been attempted, if not actually perpetrated. For a case of this kind see Casper, *op. cit.*

Unless an examination is made soon after the perpetration of the crime, the signs of it will disappear. In the case of one long habituated to these unnatural practices, certain changes have been pointed out as medical proofs,—among them a funnel-shaped state of parts between the

nates, with the appearance of dilatation, stretching, or even a patulous state of the anus, and a destruction of the folded or puckered state of the skin in this part. There may be also marks of laceration, cicatrices, &c., and sometimes evidence may be derived from the presence of syphilitic disease. This condition of parts would represent the chronic state induced by these practices in the patient or succubus. In the recent or acute form, fissure and laceration of the sphincter ani, with bruising and effusion of blood, would be found.

Trials for sodomy and bestiality are very frequent, and convictions of men and boys have taken place for unnatural intercourse with cows, mares, and other female animals. Medical evidence is seldom required to sustain the prosecution. There may be, however, circumstances which can only be properly interpreted by a scientific expert. The hair of the animal may be found on the perpetrator, or marks of blood or feculent matter upon his dress, and in such cases chemistry or the microscope may enable a witness to express an opinion in proof or disproof of the charge. In one case tried at the assizes, where a man was charged with having had unnatural intercourse with a cow, the prosecution was able to show that some short colored hairs found on the prisoner's person resembled those of the animal. This crime is punishable by penal servitude for life, under the 24 & 25 Vict., c. 100, s. 61. False charges of sodomy were at one time frequent; they were made for the purpose of extortion.

A question may arise here respecting the examination of an accused person which has already been considered in reference to women charged with infanticide. The examination should be with the consent of the accused, and not made against his will, since no one is bound to furnish evidence against himself (see *ante*, p. 663.) In reference to the evidence derivable from the hair of animals, see Horn's "Vierteljahrs.," 1865, 1, 160.

[It is a remarkable fact, that in cases of trial for rape, the maxim of the law that innocence is to be presumed until guilt is proved, is often reversed. The most glaring inconsistencies and contradictions on the part of the prosecution seem to escape the notice, or make no impression upon the mind of the jury. The remarks of Sir Matthew Hale, so often quoted that they have become trite, contain nevertheless a truth that cannot be controverted: "It is true," he says (1 Hal. P. C. 635), "that rape is a most detestable crime, and therefore ought severely and impartially to be punished with death; but it must be remembered that it is an accusation easy to be made, hard to be proved, but harder to be defended by the party though innocent." He then mentions some cases within his own observation of malicious prosecution of this crime, and adds: "I mention these instances that we may be the more cautious upon trials of offences of this nature, wherein the court and jury may with so much ease be imposed upon, without great care and vigilance, the heinousness of the offence many times transporting the judge and jury with so much indignation, that they are over-hastily carried on to the conviction of the persons accused thereof by the confident testimony of sometimes false and malicious witnesses."

Many cases might be cited to illustrate these remarks; the books are full of them, however, and it would be unnecessary to occupy space by

doing so. The conviction of Dr. Beale, for instance, was a surprise to the legal and medical professions, and could only be accounted for by this remarkable tendency on the part of the jury. In allusion to this case, Mr. Wharton, in treating of what degree of penetration is required to complete the offence of rape, says ("Med. Juris.," § 471): "Perhaps the furthest limit to which the rule has reached, is in a recent case in Philadelphia, where, though there was no medical examination, it was held that proof by the prosecutrix of pain in the sexual organ, and of the juxtaposition at the time of the defendant's face to her own—she at the time being in a dentist's chair, under the influence of ether—was enough to justify a jury in pronouncing that there was penetration, and that the penetration was sexual. The general result of both medical and legal opinion, however, is, that while the learned and able judge who tried the case, properly left it to the jury as a question of fact as he was obliged to do, to determine whether penetration had then taken place, the verdict was not sustained by the evidence, and forms an unsafe precedent for the future." And in a note to section 443 of the same work, the following remarks are added: "We sincerely believe that a great wrong may have been inflicted upon an innocent man, which can only be compensated by the probability that the fallible nature of the evidence upon which he was convicted, will hereafter render it difficult to sustain an accusation upon similar proof." In the same note is mentioned the case of a dentist in Montreal, who was indicted in 1858, for attempting to commit a rape upon one of his patients under the influence of chloroform. At the trial, a witness testified that his wife was under the strongest impression that she had been violated by the prisoner while under the influence of chloroform; yet her husband was present during the whole time she was unconscious. The verdict of the jury was, "Guilty of an attempt to commit rape, with a recommendation to mercy!"¹

¹ Sancho Panza's judgment, in the case of rape which was heard before him during his brilliant, though brief, administration as governor of Barataria, was certainly more creditable to the cause of justice. The historian thus reports it: "This cause was no sooner ended, than there came into court a woman keeping fast hold of a man clad like a rich herdsman. She came, crying aloud: 'Justice, my lord-governor, justice! If I cannot find it on earth, I will seek it in heaven! Lord-governor of my soul, this wicked man surprised me in the middle of a field, and made use of my person as if it had been a dish-clout. Woe is me! he has robbed me of what I have kept above these three-and-twenty years, defending it against Moors and Christians, natives and foreigners. Have I been as hard as a cork-tree, and preserved myself as entire as a salamander in the fire, or as wool among briers, that this honest man shall come with his clean hands to handle me?' 'That remains to be inquired into,' says Sancho: 'let us now proceed to see whether this gallant's hands are clean or not;' and turning to the man, he asked him what he had to say in answer to this woman's complaint. The man, all in confusion, replied: 'Sir, I am a poor herdsman, and deal in swine; and this morning I went out of this town, and having sold, under correction be it spoken, four hogs, and what between dues and exactions, the officers took from me little less than they were worth. As I was returning home, by the way I lighted upon this good dame, and the devil, the author of all mischief, yoked us together. I paid her handsomely; but she, not contented, laid hold of me, and has never let go of me until she has dragged me to this place. She says I forced her; but by the oath I have taken, or am to take, she lies. This is the whole truth.' Then the governor asked him if he had any silver money about him. The man answered that he had about twenty ducats in a leathern purse in his bosom. Sancho ordered him to produce it, and deliver it

In the case of *People v. Benson*, 6 Cal. 221, the court say that "no case of this class (rape) should go to the jury on the sole testimony of the prosecutrix, unsustained by facts and circumstances, without the court warning them of the danger of conviction on such testimony."—P.]

just as it was to the plaintiff. He did so trembling: the woman took the purse, and making a thousand curtsies, and praying to God for the life and health of the lord-governor, who took such care of poor orphans and maidens, out of the court she went, holding the purse with both hands, taking care first to see if the money that was in it was silver.

"She had no sooner left the room than Sancho said to the herdsman, who was in tears, and whose eyes and heart were gone after his purse: 'Honest man, follow that woman, and take away the purse from her, whether she will or not, and come back hither with it.' This was not said to one deaf or stupid, for the man instantly flew after her like lightning, and went about what he was bidden.

"All present were in great suspense, expecting the issue of this suit. In a few minutes came in the man and woman, clinging together closer than the first time, she with her petticoat tucked up, and the purse lapped up in it, and the man struggling to take it from her, but in vain, she defended it so stoutly. 'Justice from God and the world!' cried she at the top of her lungs; 'see, my lord-governor, the impudence and want of fear of this varlet, who, in the midst of the town and of the street, would take from me the purse your worship commanded to be given to me.' 'And has he got it?' demanded the governor. 'Got it!' answered the woman: 'I would sooner let him take away my life than my purse. A pretty baby I should be indeed! Other-guise cats must claw my beard, and not such pitiful, sneaking tools as this. Pincers and hammers, crows and chisels, shall not get it out of my clutches, nor even the paws of a lion. My soul and body shall sooner part.' 'She is in the right,' added the man: 'I yield myself worsted and spent, and confess I have not strength to take it from her.' That said he left her. 'Then said the governor to the woman: 'Give me that purse, chaste and valiant heroine.' She presently delivered it, and the governor returned it to the man, and said to the violent but not violated damsel: 'Sister of mine, had you shown the same, or but half so much, courage and resolution in defending your chastity, as you have done in defending your purse, the strength of Hercules could not have forced you. Begone, in God's name, and in an ill hour, and be not found in all this island, nor in six leagues round about it, upon pain of two hundred stripes. Begone. instantly, I say, thou prating, shameless, cheating hussy!' The woman was confounded and went away, drooping her head, and discontented; and the governor said to the man: 'Honest man, go home, in the name of God, with your money, and henceforward, unless you have a mind to lose it, take care not to yoke with any body.'

"The countryman gave him thanks as clownishly as he could, and went his way. The bystanders were in fresh admiration at the decisions and sentences of their new governor, all which, being noted down by his historiographer, were immediately transmitted to the duke, who waited for them with great impatience." (Don Quixote, vol. ii. 289.)

INSANITY.

CHAPTER LXI.

WHAT IS INSANITY?—MEDICAL DEFINITIONS.—DISTINCTION OF SANE FROM INSANE PERSONS.—MORAL INSANITY.—LEGAL DEFINITIONS.—“NON COMPOS MENTIS.”—SYMPTOMS OF INCIPIENT INSANITY.—HALLUCINATIONS AND ILLUSIONS.—LUCID INTERVALS.

What is insanity? Medical definitions.—The terms insanity, lunacy, unsoundness of mind, mental derangement, madness, and mental alienation or aberration, have been indifferently applied to those states of disordered mind in which a person loses the power of regulating his actions and conduct according to the ordinary rules of society. In all cases of real insanity, the intellect is more or less affected—hence the term *intellectual insanity*. In a medical sense this implies a deviation of the mental faculties from an assumed normal or healthy standard. In an insane person there may be no bodily disease, but his language and habits are changed, the reasoning power which he may have enjoyed in common with others is lost or perverted, and he is no longer fitted to discharge those duties which his social position demands. Further, from perversion of reason, he may show a disposition to commit acts which may endanger his own life or the lives of those around him. It is at this period that the law interferes for his own protection, and for that of society.

Many attempts have been made by psychologists to define insanity; but the definitions hitherto given are so imperfect that it would be difficult to find one which includes all who are insane, and excludes all who are sane. This difficulty is fully accounted for by the fact that mental disorder varies in its degree as well as in its characters; and the shades of disordered intellect in the early stages are so blended as to be scarcely distinguishable from a state of insanity. It is this twilight condition of the mind, when it is fluctuating between sanity and insanity, which no definition can comprise, especially as the mind differs in its power and manifestations in most persons, and it is therefore difficult to fix upon a standard by which a fair comparison can be made. The vulgar notion of insanity is, that it consists in an entire deprivation of reason and consciousness; but the slightest acquaintance with the insane proves that they are not only perfectly conscious of their actions in general, but that they reason upon their feelings and impressions. The late Dr. Abercrombie considered insanity to consist in a loss of the faculty of *attention*, that power by which we are capable of changing, controlling, arresting,

or fixing the current of our thoughts. Dr. Conolly regarded it as a disorder of the power of *comparison or judgment*; and Professor Marc as a loss of the faculty of *volition*; so that, in the latter point of view, the acts of the insane are, in a certain sense, involuntary, and depend upon impulses which, owing to mental disease, they are unable to control.

These definitions are defective, inasmuch as they are not adapted to the various forms of the disease. Etymologically, the term implies the negation of something, and not a positive state (Dr. Orange). In some cases of insanity, as in confirmed idiocy, there is no evidence of any exercise of the intellectual faculties; but in most instances these faculties and the moral feelings are partially diseased or partially destroyed, in every variety and degree. Thus we may meet with cases in which the faculties of attention, comparison, and volition are more or less impaired or absent, or if present, they are never perfect, although each may not be equally affected. When no two cases are precisely similar, no definition can include all varieties of the disorder. A medical witness who ventures upon a definition, will therefore generally find himself involved in numerous inconsistencies, for no words can possibly comprise the variable characters which this malady is liable to assume. Those who take an interest in definitions of insanity and who think they can defend them from the critical acumen of lawyers, will find them fully set forth in their medical and medico-legal aspects in a paper by Dr. Rorie ("Ed. Monthly Journal," July, 1865, p. 13). There are, however, cases in which a medical man may find himself compelled, if not to define insanity, at least to draw some clear distinction between a sane and an insane person. Thus in cases in which there has been an alleged breach of the law regarding the custody of lunatics, it may be pleaded that the person is sane, and a medical expert must then be prepared to say whether the person concerning whom the question is raised, is idiotic, lunatic, or of unsound mind, and to assign satisfactory reasons for his opinion.

[The difficulty of definition is thus expressed in a leader in the "London Times," of July 22, 1854, cited in Dr. Bucknill's Prize Essay on Criminal Lunacy (Law Library, vol. 92): "Nothing can be more slightly defined than the line of demarcation between sanity and insanity. Physicians and lawyers have vexed themselves with attempts at definition in a case where definition is impossible. There has never yet been given to the world anything in the shape of a formula upon this subject, which may not be torn to shreds in five minutes by any ordinary logician. Make the definition too narrow, it becomes meaningless; make it too wide, the whole human race are involved in the drag-net. In strictness, we are all mad when we give way to passion, to prejudice, to vice, to vanity; but if all the passionate, prejudiced, vicious, and vain people in this world are to be locked up as lunatics, who is to keep the key of the asylum? As was very fairly observed, however, by a learned Baron of the Exchequer, when he was pressed by this argument, if we are all mad, being all madmen, we must do the best we can under such untoward circumstances. There must be a kind of rough understanding as to the forms of lunacy which can't be tolerated. We will not interfere with the spendthrift, who is flinging his patrimony away upon swindlers, harlots, and blacklegs, until he has

denuded himself of his possessions and incurred debt. We have nothing to say to his brother madman, the miser, who pinches his belly to swell the balance at his banker's—being 73 years of age, and without family—but if he refuses to pay taxes, society will not accept his monomania as pleadable in bar."

Perhaps the definitions of sanity and insanity by Dr. Bucknill are as accurate as the subject admits of. *Sanity*, he defines to be, "that condition of the mind in which the emotions and instincts are all in such a state of subordination to the will, that the latter can direct and control their manifestations; in which, moreover, the intellectual faculties are capable of submitting to the will sound reasons for its actions. Such co-ordinate action of the faculties is termed sanity; a condition in which that is lost is termed *insanity*, or derangement, or alienation, or unsoundness, all terms having reference to the deprivation of the power of the will so directed." "It is evident," he adds, "that in this definition of sanity there are three terms, the subjected emotions, the directing intellect, and the middle term of free will. Supposing our nature to be fallible throughout its composition, it is evident that erroneous action may originate at any of these points; the mutinous emotions may be indomitable, the power of the will may be abortive, or the intellect may mislead by false guidance. Insanity may thus be Intellectual, Emotional, or Volitional, and though in the concrete it is not easy to find pure and unmixed cases under either of these heads, such cases do occasionally subject themselves to observation. The experienced psychopathist will also find little difficulty in apportioning a vast number of the other cases according to their predominant character, under one or other of these headings.

"*Insanity*, therefore, may be defined as, *A condition of the mind in which a false action of conception or judgment, a defective power of the will, or an uncontrollable violence of the emotions and instincts, have separately or conjointly been produced by disease.*"—Bucknill on Criminal Lunacy, pp. 27, 28.—P.]

Moral insanity.—In addition to that form of insanity in which the mind is affected, known as *intellectual insanity*, Dr. Pritchard and other medico-legal writers have described a state which they call *moral insanity* (*mania sine delirio*), which is manifested simply by a perverted or disordered state of the feelings, passions, and emotions, irrespective of any apparent intellectual aberration. There are no hallucinations or illusions, and there is no evidence of delusion, but simply a perversion of the moral sentiments. Thus, it is alleged that this form of insanity may appear in the shape of a causeless suspicion, jealousy, or hatred of others, especially of those to whom the affected person ought to be attached; and it may also manifest itself under the form of a wild, reckless, and cruel disposition towards mankind in general. It does not seem probable, however, that moral insanity, as thus defined, ever exists, or can exist in any person without greater or less disturbance of the intellectual faculties. The mental powers are rarely disordered without the moral feelings partaking of the disorder; and, conversely, it is not to be expected that the moral feelings should become to any extent perverted without the intellect being affected; for perversion of moral feeling is

generally observed to be one of the early symptoms of disordered reason. [See Bucknill on Criminal Lunacy, Appendix, note E.—P.] The intellectual disturbance may be sometimes difficult of detection; but in every case of true insanity it is more or less present, and it would be a highly dangerous practice to pronounce a person insane, when some evidence of its existence was not forthcoming. The law does not recognize moral insanity as an independent state; hence, however perverted the affections, moral feelings, or sentiments may be, a medical jurist must always look for some indications of disturbed reason. Medically speaking, there are, according to Dr. Pritchard, two forms of insanity, moral and intellectual: but in law there is one—that which affects the *mind*. Moral insanity is not admitted as a bar to responsibility for civil or criminal acts, except in so far as it may be accompanied by *intellectual* disturbance. [But see the case of *Reg. v. Crockroft* (Leeds Autumn Assizes, 1865), cited post, in chapter 63. It is admitted in Pennsylvania. See cases of *Com. v. Mosler*, 4 Barr 266. *Com. v. Shurlock*, 14 Leg. Int. 33. *Ib. v. Smith*, 15 Leg. Int. 33. *Ib. v. Freath*, 6 Am. Law Register, p. 400. See also Lewis's Crim. Law 404. In most of the States, however, the law is as stated in the text, and the test still is the knowledge of right and wrong. See *Farrar v. State*, 2 Ohio St. R. 54. *State v. Spencer*, 1 Zabrieski 196 (New Jersey). *Fisher v. People*, 23 Ill. 283. *Loeffner v. State*, 10 Ohio (N. S.) 598.—P.] Dr. Mayo denies its existence, and contends that no abnormal state of mind should confer irresponsibility unless it involves intellectual as well as moral perversion. ("Medical Testimony," p. 69.) The late Sir B. Brodie also considered that there are no reasonable grounds for admitting this to be an independent form of insanity. There has been, as he suggests, much mystification on the subject. The term has been applied to cases in which the name of insanity ought not to have been applied at all, *i. e.*, to "moral depravity," and also to cases in which delusions have really existed, and which might therefore have been more properly classed with cases of ordinary mental aberration. ("Psychological Inquiries," p. 99.) Of one fact we may be well assured; if in these cases of alleged *moral* insanity there is no indication of a perversion of intellect, *medical* evidence is not required to determine the fact, or the degree of responsibility in reference to these persons. Those who administer the law, and any man endowed with plain common sense will be as well qualified as a medical expert, to decide the question of criminal responsibility. Further, until medical men can produce a clear and well-defined distinction between moral depravity and moral insanity, such a doctrine, employed as it has been for the exculpation of persons charged with crime, should be rejected as inadmissible.

Legal definitions.—The law of England recognizes two states of mental disorder or alienation: 1. *Dementia naturalis*, corresponding to idiocy; and 2. *Dementia adventitia*, or *accidentalis*, signifying general insanity as it occurs in persons who have once enjoyed reasoning power. To this state the term lunacy is also applied, from an influence formerly supposed to be exercised on the mind by the moon. *Lunacy* is a term generally applied to those disordered states of mind which are known to medical men under the names of mania, monomania, and dementia; and

which are frequently, although not necessarily, accompanied with lucid intervals. The main character of insanity, in a legal view, is considered to be the existence of *delusion*, *i. e.*, that a person should believe something to exist which does not exist, and that he should act upon this belief. Many persons may labor under harmless delusions, and still be fitted for their social duties; but should these delusions be such as to lead them to injure themselves or others in person or property, then the case is considered to require legal interference.

In addition to the terms *Idiocy* and *Lunacy*, we find another frequently employed in legal proceedings, namely, "*unsoundness of mind*"—(*non compos mentis*)—of the exact meaning of which it is impossible to give a consistent definition. According to Dr. Forbes Winslow, the phrase "*unsoundness of mind*" was first used by Lord Eldon to designate a state of mind not exactly idiotic, and not lunatic with delusions, but a condition of intellect occupying a place between the two extremes, and unfitting the person for the government of himself and his affairs. ("Lancet," 1872, 1, 108.) This definition has been since generally accepted and acted on by all the judges. From various legal decisions, it would appear that the test for unsoundness of mind in law has no immediate reference to the existence of *delusion* in the mind of a person, so much as to proof of incapacity from some morbid condition of intellect to manage his affairs with ordinary care and propriety. (Amos.) Neither condition will suffice to establish unsoundness without the other; for the intellect may be in a morbid state, and yet there may be no legal incompetency; or the incompetency alone may exist and depend on bodily infirmity or want of education—conditions which must not be confounded with mental disorder. Thus, then, a person may be of unsound mind, *i. e.*, legally incompetent to the control of his property, and yet not come up to the strict legal standard of lunacy or idiocy.

Some medical practitioners have attempted to draw a distinction between *insanity* and *unsoundness of mind*. A case occurred in 1839, in which a medical man hesitated to sign a certificate for the confinement of an alleged lunatic, because in it the words "*unsound mind*" were used. He said he would not have hesitated to sign it had the term "*insane*" been employed. The difference, if any exist, is purely arbitrary, and depends on the fact that "*unsound mind*" is a legal and not a medical phrase, referring to an incapacity to manage affairs, which insanity, in its most enlarged sense, does not always imply. The law, however, appears to admit some sort of distinction: for, according to Chitty, it is a criminal and an indictable act maliciously to publish that any person is afflicted with insanity, since it imputes to him a malady generally inducing mankind to shun his society; although it is not libellous to say that a man is not of sound mind, because no one is of perfectly sound mind but the Deity! ("Med. Jur.," vol. 1, p. 351.) In reference to the signing of certificates of insanity, it is, however, an error to suppose that the use of one term can involve a practitioner in any greater share of responsibility than the use of the other.

Symptoms of incipient insanity.—The symptoms by which insanity is indicated at an early stage are liable to great variation, according to the sex, age, and social position of the person. In reference to suicide,

the execution of wills, or the perpetration of crime, we often find, after the death of the person, or at the trial which follows the crime, that the most trivial and irrelevant circumstances are brought forward as indications of insanity. This subject has been ably treated by Dr. Forbes Winslow ("Obscure Diseases of the Brain," p. 88), and to his work I must refer the reader for much useful information. The facts are there gathered chiefly from the accounts furnished to him by those who have recovered. There is great irritability at the most trifling circumstances—impatience of contradiction, loquacity, great difficulty in directing attention to, and steadily occupying the mind with any train of thought, neglect of usual employment, sleeplessness, depression of spirits without reasonable cause, a disposition to seclusion, doubts about personal identity followed by hallucinations and illusions. A lady, who was gradually affected, remained insane for nearly eleven months: she informed Dr. Winslow that during the whole of that time she fancied she was in hell and tormented by evil spirits; she thought every person near her was the devil. Sometimes a patient fancies he is continually watched by spies, that policemen are looking after him, and that conspiracies and plots among his relatives or friends are going on secretly against him; he believes that his food is drugged or poisoned, and will refuse to eat. Great anxiety on any subject followed by headache may be the forerunners of an attack; there is generally an entire loss of interest in the usual occupations, a silent manner, and a great desire for solitude. In one instance, fits of immoderate laughter at the most trivial occurrences preceded the attack. Sooner or later these symptoms are attended by perverted taste or smell—by illusions of hearing or sight; voices are heard, and objects are seen, which at first perplex and then confuse the patient; they continue until he feels overpowered mentally and bodily; and he then falls into delusions regarding himself, his friends who are about him, his profession or occupation, and his worldly circumstances.

In incipient insanity delusion does not necessarily exist. There is an antecedent state, in which, according to Dr. C. B. Radcliffe, the most prominent feature is intense *self-conceit*. A man may retain the knowledge of his personal identity, but he may fancy himself to be wiser, richer, or stronger than he really is. Another feature is *misanthropy*, a general dislike to others without cause, but especially directed against those who have the greatest claim on his affection. This feeling may after a time become complicated with some delusion. A third symptom is a *suspicious disposition*, which sooner or later leads to delusion, and the person imagines that there are conspiracies to poison him or to do him some bodily injury. (Croonian Lectures, "Lancet," April, 1873, p. 471.) Intense self-conceit, misanthropy, and distrust without delusion, may be regarded as the most marked forerunners of an attack of insanity.

Hallucinations and illusions.—These are the most striking symptoms which are met with in a confirmed state of insanity. Hallucinations are those sensations which are supposed by the patient to be produced by external impressions, although no material objects act upon his sense at the time; illusions, on the other hand, are sensations produced by a false perception of objects. A man has visions of all kinds, including

the forms of the dead and the living, floating before him, when he is gazing upon vacancy. He fancies he hears voices speaking or mysteriously whispering to him, while there is profound silence—these are hallucinations. Another may erroneously imagine that the taste or smell of his ordinary food is earthy, metallic, or poisonous, when the perversion is in his own senses—these are illusions. Both conditions depend upon a disordered state of the mind. Instances of hallucination are furnished by the act of dreaming; while illusions occur often during the act of suddenly waking from sleep—giving rise occasionally to serious questions involving criminal responsibility. The state of insanity is in other points of view analogous to dreaming. There is equally a want of power in the two states to change or control the current of thought passing through the mind. Things which are impossible and inconsistent are believed to have an actual existence. A voice heard during the act of dreaming sometimes becomes an illusion connected with a current of thought then passing through the mind; it is the same in a case of confirmed insanity, with this difference in the latter, that some power of will or some exercise of reason may still exist.

Illusions are sometimes met with in the sane; but when arising from external objects, the false perception is soon corrected by a reference to the other senses; and herein consists the main difference between sanity and insanity—namely *delusion*, or a misleading of the mind. When the hallucination or illusion is believed to have a positive existence, and this belief is not removed either by reflection or an appeal to the other senses, the person is insane; but when the false sensation is immediately detected by the judgment, and is not acted on as if it were real, then the person is sane. *Delusion*, therefore, properly refers to the judgment, and *illusion* to the senses. The meaning of these terms is often confounded; but while delusion is always connected with insanity, illusion is not necessarily indicative of mental disorder. Hallucinations and illusions are the main features of those forms of insanity which are known as mania and monomania. They are rarely met with in cases of idiocy and imbecility, sometimes in dementia, but they are most common in paroxysms of mania. Acts of murder may generally be traced to their existence, for the person laboring under mania or monomania is unable during a paroxysm to divest his mind of the belief that what he sees has a positive existence before him. He feels impelled to suicide by the hallucination of voices calling to him, and to murder by the illusion that he is not destroying a wife, child, or friend, but an evil spirit substituted for them. The acts of the insane are generally connected with their delusions, although it is not easy to trace the connection, except by their own admissions. When the acts are unusual and strange, it is most probable that they depend on hallucination, illusion, or both.

Lucid intervals.—By a lucid interval we are to understand, in a legal sense, a temporary cessation of the insanity, or a perfect restoration to reason. This state differs entirely from a remission, in which there is a mere abatement of the symptoms. It has been said that a lucid interval is only a more perfect remission, and that although the lunatic may act rationally and talk coherently, yet his brain is in an excitable state, and he labors under a greater disposition to a fresh

attack of insanity than one whose mind has never been affected. Of this there can be no doubt, but the same reasoning would tend to show that insanity is never cured; for the predisposition to an attack is undoubtedly greater in a recovered lunatic than in one who is and has always been perfectly sane. Even admitting the correctness of this reasoning, it cannot be denied that lunatics do occasionally recover for a longer or shorter period, to such a degree as to render them perfectly conscious of and legally responsible for their actions like other persons. The law intends no more than this by a lucid interval; it does not require proof that the cure is so complete that even the predisposition to the disease is entirely extirpated. Such proof, if it could even be procured, would be totally irrelevant. If a man acts rationally and talks coherently, we can have no better proof of a restoration to reason. If no delusion affecting his conduct remains in his mind, we need not concern ourselves about the degree of latent predisposition to a fresh attack which may still exist. Lucid intervals sometimes appear suddenly in the insane; the person feels as if awakened from a dream, and there is often a perfect consciousness of the absurdity of the delusion under which he was previously laboring. The duration of the interval is uncertain; it may last for a few minutes only, or may be protracted for days, weeks, months, and even years. In a medico-legal view, its alleged existence must always be looked upon with suspicion and doubt when the interval is very short.

Lucid intervals are most frequently seen in cases of mania and monomania; they occasionally exist in dementia, when this state is not chronic, but has succeeded a fit of intermittent or periodical mania. They are never met with in cases of idiocy and imbecility. It is sometimes a matter of great importance to be able to show whether or not there exists or has existed a lucid interval, since in this state, the acts of a person are deemed valid in law. The mind should be tested, as in determining whether the patient is laboring under insanity or not. He should be able to describe his feelings, and talk on the subject of his delusion, without betraying any sign of unnecessary vehemence or excitement. It may happen that the person who is the subject of a Commission of Inquiry is at the time of examination, under a lucid interval, in which case there may be some difficulty in forming an opinion of the existence of insanity. It has been said that a person in a lucid interval is considered by law to be responsible for his acts, whether these are of a civil or criminal nature. In regard to criminal offences committed during a lucid interval, it is the opinion of some medical jurists that no person should be convicted under such circumstances, because there is a probability that he might at the time have been under the influence of that degree of cerebral irritation which renders a man insane. (Pritchard.) This remark applies especially to those instances in which the lucid interval is very short. Juries now seldom convict, however rationally in appearance a crime may have been perpetrated, if it can be clearly proved that the accused was really insane within a short period of the time of its perpetration.

The number of lunatics in England and Wales in 1878 was 68,538, exclusive of those so found by inquisition and criminal lunatics. In this number 31,024 were males, and 37,514 females.

CHAPTER LXII.

VARIETIES OF INSANITY.—MANIA.—ABSTINENCE FROM FOOD.—DELUSIONS REGARDING POISON.—DELIRIUM DISTINGUISHED FROM MANIA.—MONOMANIA.—DEMENTIA.—IDIOCY.—IMBECILITY.—HEREDITARY TRANSMISSION.—FEIGNED INSANITY.—APPEARANCES AFTER DEATH.—ECCENTRICITY.

Varieties of insanity.—Medical jurists have commonly recognized four distinct forms of insanity: *Mania*, *Monomania*, *Dementia*, and *Idiocy* (*Amentia*). This division was proposed by Esquirol, and although of a purely artificial nature, it is highly convenient for the arrangement and classification of the facts connected with the subject. In some instances there is great difficulty in assigning a particular case to either of these divisions, which is owing to the circumstance that these states of disordered mind, if we except idiocy, are frequently intermixed, and are apt to pass and repass into each other. On other occasions a case may represent mixed characters which appertain to all the divisions. Some psychologists have proposed two subdivisions—namely, *Incoherency* and *Imbecility*; but the former is merely a mixed state of mania and dementia, while the latter is a term applied to those cases of idiocy wherein the mental faculties are susceptible of some degree of cultivation after birth, without reaching the normal standard.

Mania.—In this form of insanity there is a general derangement or perversion of the mental faculties, accompanied by greater or less excitement, sometimes amounting to violent fury. (Pagan's "Med. Jur. of Insanity," p. 59; Marc. "De la Folie," vol. 1, p. 211.) Ideas flow through the mind without order or connection, the person losing all control over his thoughts, and believing and acting upon them, however absurd and inconsistent they may be. Rapidity of utterance and incessant agitation accompany this state; there is also great irritability, so that not the least contradiction can be borne. Mania may take place suddenly, as after a violent moral shock, but in general it comes on slowly. It may be chronic or acute, recurrent or continued. There are very few cases which do not present remissions, more or less complete; and in some instances after a violent attack, the reason appears to be perfectly restored, forming then what is termed a lucid interval, the clear distinction of which, in a legal point of view, is of material importance. In *recurrent mania* the attack comes on without any obvious cause. It may last for a week, a month, or even longer. There is usually a stage of excitement followed by depression before recovery. Persons laboring under mania, especially when it is associated, as it frequently is, with paralysis, are comparatively insensible to severe injuries. They will bear exposure to cold without complaining, and even conceal the ex-

istence of a fracture or other injury, which would cause great pain to a sane person. They will also sustain the privation of food for a great length of time without any apparent injury to health. In some instances, owing to a suspicion that the food is poisoned, they refuse to take any; it is then necessary to feed them with a stomach-pump. (Winslow's "Obscure Diseases of the Brain," p. 71.) This delusion respecting the poisoning of food is very common in the early stages of mania. The patient will fancy that he himself, or some favorite animal, is undergoing a process of slow poisoning by a secret enemy. This is so frequent a delusion that Dr. Cameron has proposed to treat it as a distinct form of insanity under the name of *toxiphobia*, or perhaps more strictly *toxicomania*. He has noted 63 cases, in only two of which there was obvious insanity. I have met with a great number of instances in which this delusion of being the victim of poison was the principal feature of the mental disorder. In mania there is excitement coming on in paroxysms without any obvious cause, and leading the person to acts of violence either towards himself or others.

It is necessary that a medical jurist should be able to distinguish *mania* from delirium depending on bodily disease. *Delirium* closely resembles the acute form of mania,—so closely that mistakes have occurred, and persons laboring under it have been improperly ordered into confinement as maniacs. The following are perhaps the best diagnostic differences: A disordered state of the mind is the first symptom remarked in mania; while delirium is the result of bodily disease, and there is greater febrile excitement in it than in mania. Delirium, being a mere symptom attendant on the disease which produces it, exists as long as the disease and no longer: while mania, depending on widely different causes, is persistent. Delirium disappears suddenly, leaving the mind clear; while mania commonly experiences only remissions. (See Pagan's "Med. Jur. of Insanity," p. 69.) In delirium there is generally great acuteness of the senses. Inflammation of the brain or its membranes (*phrenitis*) is distinguished from acute mania by the mode of its attack, the presence of severe pain in the head, and excessive sensibility, with intolerance of light and sound.

Monomania.—This name is applied to that condition in which the mental alienation is only partial; in other words, it is nothing more than partial insanity. In mania, the mind is disordered on all kinds of subjects; in monomania the disorder is confined chiefly either to one subject or to one class of subjects. Monomaniacs are infected with false ideas on certain points, of which they cannot divest themselves, and out of which they cannot be reasoned: they start from false principles, but setting this aside, their inferences and deductions from these principles often possess logical accuracy. In every subject not connected with their special delusions they are like the rest of the world; they talk and reason as justly upon facts as before the access of their malady, but their general deportment, habits, and character are changed. Thus a miser may become a spendthrift, and a hard-working and industrious mechanic may pass his time in idleness; a man of moral habits will become immoral in conversation and conduct, and an abstemious man may become a drunkard.

The monomania may be so slight that the person will have the power of so controlling his thoughts and actions as to appear like one who is sane, provided the subject of his delusion is not referred to. There is no doubt that those who are affected with monomania in an early stage, are frequently able to direct their minds with reason and propriety to the performance of their social duties, so long as these do not involve any of the subjects of their delusions. Their power of controlling their thoughts and feelings, as well as of concealing their delusions, implies a certain consciousness of their condition not usually met with in mania; and it also appears to imply the existence of such a control over their conduct as to render them equally responsible with sane persons for many of their acts. In a case of confirmed monomania, however, it is not to be supposed that a man is insane upon *one* point only, and sane upon all other subjects. The only admissible view of this disorder is that which was taken by Lord Lyndhurst, in one of his judgments. In monomania the mind is unsound; not unsound in one point only, and sound in all other respects, but this unsoundness manifests itself principally with reference to some particular object or person. (Prichard.) There is no doubt that all the mental faculties are more or less affected, but the affection is more strikingly manifested in some of these than in others.

The delusion of a monomaniac will be generally uppermost in his mind; his will is powerless to dismiss it, just as in mania the will is powerless to stop the continuous and rapid succession of different and incongruous ideas which present themselves to the mind in that form of insanity. In the first stage of monomania the judgment may be strong, and the mind apparently sound upon every point except the particular subject of delusion; and even, in some instances, there may be such a control over this delusion that it would be difficult to discover whether or not there was any just ground for imputing mental unsoundness; but in a more advanced form of the disease, the delusion, whatever it may be, whether relating to wealth, ambition, religion, or politics, so overpowers the patient, that he loses self-control. His character is changed, and his habits are such as to render him unfit for social intercourse; he becomes incoherent; his ideas are perverted on all subjects, and he gradually lapses into mania or dementia. The last condition happens when the monomania is of long standing. Monomania may be remittent or intermittent, and it is sometimes accompanied with lucid intervals. Its progress is rapid, and its termination often unexpected: in some instances the disease ceases suddenly, without any previous warning, owing to the effects of a strong moral shock or impression.

Monomania in its early stage is liable to be confounded with *eccentricity*; but there is this difference between them: in monomania there is obviously a change of character,—the person is different from what he was: in eccentricity such a difference is not remarked; he is, and always has been, singular in his ideas and actions—there is no observable change of character. An eccentric man may be convinced that what he is doing is absurd, and contrary to the general rules of society, but he professes to set these rules at defiance; a true monomaniac cannot be convinced of his error, and he thinks that his acts are consistent with

reason and the general conduct of mankind. In eccentricity there is the will to do or not to do : in real monomania the controlling power of the will appears to be lost. Eccentric habits suddenly acquired are, however, presumptive of insanity. It will be seen hereafter that the distinction of these states is of considerable importance in relation to the testamentary capacity of persons.

Monomania frequently assumes one of two forms : either the thoughts are lively and gay, or they are oppressed with gloomy melancholy. In the first state, the persons will fancy themselves to be kings and queens, and overflowing with wealth, which they are prepared to distribute with regal profusion ; in the second state, we find silence, seclusion, and the most heartrending sorrow. The latter condition, by no means uncommon as a form of monomania, is called *melancholia* (mania with depression), or *lypemia* (λύπη, sorrow). Those who are affected with it suppose they have committed some unpardonable sin, and pass their hours in silence and in the most gloomy forebodings of temporal and eternal punishment. They do not sleep, and will sometimes neither eat, speak, nor move ; force must be used to make them take food and exercise. In some instances no persuasion can conquer their silence ; one patient thus affected was not heard to utter a word during four years. If spoken to, they shed tears and violently repulse the person who addresses them. Melancholia frequently leads to an act of suicide or murder, and persons affected with it require very close watching. In the lighter forms of the disease there is no sign of mental aberration, and the patient will go through his usual routine of duty, but always with the same desponding air—so that his occupation seems scarcely to distract his thoughts from the delusion for a single instant. In other cases the delusion is so well concealed that no suspicion exists, until an act of suicide leads to inquiry, and some evidence of strangeness of conduct is then for the first time forthcoming. There is either an entire absence of motive for the act, or the motive is based on a delusion.

Dementia.—This is a state which, although sometimes confounded with mania, is very different in its characters. Dementia, when confirmed, consists in a total absence of all reasoning power, and an incapacity to perceive the true relations of things ; the language is incoherent, and the actions are inconsistent ; the patient speaks without being conscious of the meaning of what he is saying ; memory is lost, and sometimes the same word or phrase is repeated for many hours together ; words are no longer connected in meaning, as they are in mania and monomania. This state is often called *fatuity* ; it is a not unfrequent consequence of protracted mania or monomania.

Dementia varies in degree. The disordered mind of aged persons is one form of dementia ; here we find memory and some mental power, although the memory is restricted to objects long since past, and the exertions of the mind are only momentary. Some persons in dementia are quiet, others are in constant motion as if in search of something. There is generally a strong disposition manifested to collect all kinds of useless articles, which are hoarded up as if they were of great value. In some instances this disease comes on gradually—the faculties, both moral and intellectual, decay one by one ; while in other instances, although much

more rarely, dementia may occur suddenly from a violent shock or impression on the mind. Dementia may be acute or chronic, remittent or intermittent. The countenance of the patient is generally pale, vacant, and without expression, the look vague and uncertain, and tears are abundantly shed from the slightest causes.

The following may be taken as the most striking differences between mania and dementia. In mania there is an incoherence of ideas, but depending on too great rapidity of thought and excitement of the intellectual powers; in dementia there is a want of ideas, and the incoherence depends on the loss of the power of connecting them, owing to defect of memory; volition is lost and the brain seems in a state of collapse. (Esquirol, "*Maladies Mentales*," vol. 2, pp. 224 and 232.) In fact, in dementia there is a more or less complete abolition of the moral, intellectual, and voluntary powers; in mania, and also in monomania, they are in a state of perversion. Dementia is often a consequence of these states, and sometimes alternates with them.

Idiocy. Imbecility.—Idiocy is the *dementia naturalis* of lawyers. The term idiot is applied to one who from original defect has never had mental power. Idiocy differs from the other states of insanity in the fact that it is marked by a congenital deficiency of the mental faculties. There is not here a perversion or a loss of what has once been acquired, but a state in which, from defective structure of the brain, the individual has never been able to acquire any degree of intellectual power to fit him for his social position. It commences with life and continues through it, although idiots are said rarely to live beyond the age of thirty. (Esquirol, "*Maladies Mentales*," vol. 2, p. 284.) The deficiency of intellect is marked by a peculiar physiognomy, an absence of all expression, and a vague unmeaning look; there is no power of speech, or only the utterance of a cry or sound; there is no will, but the actions of these beings appear to depend upon impulse, a power of imitation, or mere animal instinct; they recognize no one, they remember no one, and the mind seems to be a blank. Such is the picture of what may be termed a complete idiot. In Switzerland this state of idiocy is often accompanied with great bodily deformity and enlargement of the thyroid gland, both in males and females; it is there termed *cretinism*. Cretins resemble monsters more than human beings. A confirmed idiot may in almost all cases be recognized by the expression of countenance and the form of the skull.

Idiocy is not always so complete as this description implies. There is a state scarcely separable from idiocy in which the mind is capable of receiving some ideas, and of profiting to a certain extent by instruction. Owing, however, either to original defect, or to a defect proceeding from arrested development of the brain as a result of disease or other causes operating after birth, the minds of such persons are not capable of being brought to a healthy standard of intellect, like that of an ordinary person of similar age and social position. This state is called *imbecility*; it is nothing more than idiocy in a minor degree. In common language, persons laboring under it are often called idiots, but for the sake of precision in medical language they are more correctly described as imbeciles. (Esquirol, *op. cit.*, vol. 2, p. 289.) In imbecility the physical

organization differs but little from the ordinary standard ; the moral and intellectual faculties are susceptible of cultivation, but to a less degree than in a perfect man, and even this capacity does not exist beyond a certain point. Imbeciles never attain a normal standard of intellect, and when placed in the same circumstances as other men, they never make a similar use of their intellectual powers. They can form no abstract ideas, and sometimes their capacity to receive instruction is restricted to a certain subject—as, for instance, arithmetic. Their memory and judgment are limited, although sometimes the former is remarkably strong. They express themselves in a hesitating manner, and differently from other men ; they require time to perceive the relations of objects which are immediately perceived by sane persons. The degree in which imbecility exists is well indicated by the power of speech. In idiots there is no speech, or only an utterance of single words ; in the better class of imbeciles the speech is often easy and unaffected, while there is every grade between these two extremes. Some have arranged imbeciles in classes, according to their capacity to receive instruction—others according to their power of speech ; but such divisions are practically without value : each case must be judged by itself. The precise boundary between idiocy and imbecility cannot be defined. The major degrees of imbecility approach so closely to those of idiocy, that there is no distinction between them, and in a practical view no distinction is required. Idiocy has been here described as that condition in which the congenital effect is not susceptible of being removed by any kind of instruction ; but many medico-legal writers apply the term idiot to one who does manifest capacity to receive instruction, although in a low degree. The difference is immaterial so long as the meaning of the word is understood.

How are the minor degrees of imbecility to be distinguished from sanity ? This is a question by no means easy to answer, for the reason that sane persons differ remarkably in their mental power to receive instruction, to retain what they have been taught, and to allow them to make a practical use of it in the world for their own benefit. How many persons pass through life and advance in the world who are yet undoubtedly weak-minded, and who have the reputation among all who know them of being so ! The truth is, the lowest degrees of intelligence legally constituting sound mind, are not separable from the minor forms of imbecility, so far as the moral and intellectual faculties are concerned. By running this distinction too closely, one half of the world might easily reason itself into the right of confining the other half as insane.

Idiocy and imbecility must not be confounded with mania and monomania. In idiots and imbeciles ideas are wanting, and the power of thought is absent or defective ; in maniacs and monomaniacs the ideas flow freely, but they are perverted, and the power of thought is irregular and uncontrolled. In idiocy and imbecility we do not meet with the hallucinations and illusions which constitute the main features of mania and monomania. Idiocy is much more likely to be confounded with dementia, and indeed, when dementia is confirmed and complete (*fatuity*), there is no appreciable difference, for in neither state is there any evidence of the exercise of mental power. In idiocy no ideas have ever been formed ; in imbecility they have been partially formed, but

arrested ; in dementia they have been more or less completely formed, but have subsequently become entirely obliterated. It is important to remember that in idiocy and imbecility there is no gradual loss or sudden impairment of the mental faculties, as is generally observed in dementia ; the person is what he always has been—mentally weak and unsusceptible of any great degree of improvement by instruction.

From these remarks it will be seen that imbecility is a state existing from birth or from childhood—for it is possible that it may supervene from disease after birth, in a child in whom there was no reason to suspect its existence—but it is more common to find the deficiency congenital. Still, the term is often applied to that weakness of the mental powers which takes place in the aged at the close of life, even when the mind has been well developed in maturity. Thus we speak of the imbecility of age ; this is truly nothing more than a state of *senile dementia*, and to apply to it the term “imbecility” tends to create confusion.

Such then are the four forms under which insanity or mental aberration may present itself to our notice, and although there are occasionally mixed states, as of mania and dementia (*incoherency*), yet it is an important feature in the distinction of mental disorders, to observe that in real insanity the characters presented to us in any given case, do not vary materially from those which have been described as peculiar to each of these states. This medical classification, it must be remembered, is made for the sake of convenience, because by it a practitioner may be led to form a safe diagnosis of the real state of mind of a person. It is not recognized in any of the law-proceedings connected with the insane ; for in these the term *unsoundness of mind*—comprehending lunacy, idiocy, imbecility, and all forms of mental weakness—is almost exclusively employed. In adopting this arrangement, a medical jurist must take care not to fall into an error which has been sometimes committed—*i. e.* of pronouncing a person to be of sound mind, because his case could not be easily placed in any one of these four great divisions of insanity. This would be as serious an error as that formerly committed by some law authorities—namely, of giving restricted and incorrect definitions of lunacy, idiocy, and imbecility, and then contending whoever was not a lunatic, idiot, or imbecile, according to these arbitrary legal definitions, must be a person of sound mind.

Hereditary transmission.—The hereditary transmission of insanity has sometimes presented itself as a medico-legal question in relation to the criminal responsibility of the insane. According to Chitty it is an established rule of law, “that proof that other members of the same family have decidedly been insane is not admissible either in civil or criminal cases.” (“*Med. Jur.*,” vol. 1, p. 352.) But recent decisions have shown that this statement is not correct. In *Reg. v. Ross Touchet* (1844), in which the accused was tried for shooting a man, and acquitted on the ground of insanity, Maule, J., held that evidence that the grandfather had been insane might be adduced, after it had been proved by medical testimony that such a disease is often hereditary in a family. It was also admitted in *Oxford’s* case—the prisoner having been tried for shooting at the Queen (“*Law Times*,” Oct. 26, 1844), and since that

date it has been admitted in a number of cases in which insanity was urged as a defence on a charge of murder. This kind of evidence has, however, been frequently rejected, and it is not admitted by the law of Scotland. (*Gibson's case*, Edinburgh, December, 1844.) [It was also admitted in Pennsylvania, in the case of *Smith v. Kramer*¹ (1 Am. Law Reg. p. 355), upon the question of a testator's sanity. So in Massachusetts, *Barter v. Abbott* (7 Gray, 71). In Delaware, in a trial for murder, the evidence was admitted, and it was said "that reputation in the family of such cases (of insanity) may be proved on the principle of births, deaths, genealogies, etc." (*State v. Windsor*, 5 Harrington, 512.) In *State v. Christmas* (6 Jones, Law North Carolina, 471), it was held that where hereditary insanity is offered as an excuse for crime, it must appear that the kind of insanity proposed to be proven, as exist-

¹ [Chief Justice Gibson, in admitting the evidence in this case, thus expressed himself: "I admit the deposition without hesitation, notwithstanding the dicta of Mr. Shelford ('Treat. on Lunacy,' 59), and Mr. Chitty ('Med. Juris.' 355), that it is an established rule of law not to admit proof of insanity in other members of the family in civil or criminal cases. Established? When, where, and by whom? Certainly not by the House of Lords in *McAdam v. Walker* (1 Dow's Par. Ca. 148), the only case cited for it, for the question there was avowedly dodged. That high court would not shock common sense by affirming the order of the Scotch Court of Sessions; nor would it gratuitously reverse it, where the decision could be safely put on another ground. The authority of a judgment appealed from, and left in dubio, cannot be very great." . . . "Does not proof of hereditary madness bear directly on the condition of the mind which is the subject of investigation?"

"What if the point had been ruled by the Chancellor and law judges in the House of Lords? Profoundly learned in the maxims of the law, they were profoundly ignorant of the lights of physiology; yet, free from the presumptuousness of which ignorance is the foster-father, they refused to rush on the decision of a question to which they felt themselves incompetent." . . . "When it is admitted by Mr. Chitty and Mr. Shelford themselves, that insanity is a descendible quality, they give up the argument. There can be nothing unreasonable in referring wild, furious, and unnatural actions, not otherwise accounted for, to the aberrations of a mind, the reflex of that of a crazy father. Mr. Taylor, a distinguished lecturer on Medical Jurisprudence in Guy's Hospital, London, says that 'in making a diagnosis of a case of insanity, the first question put is commonly in reference to the present or past existence of the disorder in other members of the family. There can be no doubt, from the concurrent testimony of many writers on insanity, that a disposition to the disease is frequently transmitted from parent to child, through many generations. M. Esquirol has remarked that this hereditary taint is the most common of all causes to which insanity can be referred.' (Taylor on Med. Juris. 502.)" . . . "The knowledge attained by men of a subject with which they have grappled all their lives, ought surely to prevail against knowledge gleaned from the hand-books of a profession to which the gleaners did not belong. Strange that a source of information, open to every one else, should be closed to those who are to pass on the fact! Every man has observed that there are families, through which insanity has been handed down for generations."

"An objection to the inquisition which does not disclose the specific nature of the ancestor's infirmity might stand in a different light, but testimony which brings the fact of madness home to him ought to be received like evidence of family likeness, which, though less reliable, was allowed to be corroborative proof of pater-nity in the Douglas Peerage case in 1767, and again in the Townsend Peerage case in 1843." . . . "In prosecutions for bastardy, the practice in the Quarter Sessions was, in my day, not exactly to give the child in evidence, but to put it before the jury, sometimes by the prosecutor, and sometimes by the putative father. But ancestral irregularity in the action of the brain is more frequently transmitted than any resemblance in form or feature; and it is difficult to imagine an objection to evidence of it for purposes of corroboration."—P.]

ing in the prisoner, is no temporary malady ; but that it is notorious, and of the same species as that with which other members of the family have been afflicted.—P.]

Feigned insanity.—Insanity is sometimes feigned by persons accused of criminal offences in order to procure an acquittal or discharge. In the first place, when feigning is suspected, it will be proper to inquire whether the person has any *motive* for pretending to be insane. No sane person feigns without a motive. It is necessary to remember that insanity is never assumed until *after* the commission of a crime and the actual detection of the criminal. No one feigns insanity merely to avoid suspicion. In general, as in most cases of imposture, the part is overacted—the person does either too much or too little, and he betrays himself by inconsistencies of conduct and language which are never met with in cases of real insanity. There is commonly some probable cause to which insanity may be traced, but when the malady is feigned there is no apparent cause ; in this case the appearance of the assumed insanity is always sudden—in the real malady, the progress of an attack is generally gradual ; and when the attack is really sudden, then it will be found to be due to some great moral shock or other very obvious cause. We should observe whether for some time previously, there has been any marked change of character in the person, or whether his conduct, when he had no interest to feign, presented any of the usual indications of a disordered mind. Some difficulty may arise when fits of eccentricity or strangeness of character are deposed to by witnesses ; but these statements may be inconsistent with each other, and the previous acts of the person may bear no resemblance whatever to those performed by him in the recently assumed condition. A difficulty of this kind rarely presents itself, since in an impostor no act indicative of insanity, can be adduced for any antecedent period of his life ; it is only *after* the perpetration of a crime and its detection, that any action simulating the habits of the insane will be met with. In real insanity the person will *not* admit that he is insane ; in the feigned state all his attempts are directed to make you believe that he is mad ; and an impostor may be induced to perform any act, if it be casually observed to another in his hearing that the performance of such an act will furnish strong evidence of his insanity.

Mania is perhaps more frequently assumed than any other form, because the vulgar notion of insanity is, that it is made up of violent action and vociferous and incoherent language ; but mania rarely comes on suddenly, or without some obvious cause. A maniacal patient is equally furious day and night, while an impostor is obliged to rest after his violent exertions. Dr. Burrows recommends that close attention should be paid to the expression of the eye. The mobility of the features may be as rapid as the imagination is vivid ; but when every feature may vary, or be kept under control and be steady, the eye will still indicate the erring thought—its expression cannot be easily assumed. There is about the eyes in mania a restlessness which cannot fail to attract attention ; the patient sleeps but little, and the sleep is disturbed—an impostor sleeps as soundly as a healthy person. The violence of a maniac continues whether he is alone or not, while the impostor acts his part only when he

thinks he is observed ; hence the imposition may be detected by watching him when he is not aware that an eye is directed upon him.

The feigning of *monomania* is a matter of some difficulty ; it would be easily susceptible of detection. As in mania, the part would be overacted, and an impostor would thus betray himself. *Dementia* is more easily feigned ; in general this state comes on slowly, and is obviously dependent on organic changes, as old age, apoplexy, paralysis, or hemiplegia ; or it is a consequence of recurrent mania or monomania. As this form of insanity consists in an entire abolition of all mental power, so the discovery of any connected ideas, reasoning, or reflection, either by language, writing, or gestures, would at once show that the case was not one of real dementia. *Idiocy* and *imbecility* could hardly be feigned successfully, because these are states of congenital deficiency ; they must have existed from birth, of which, of course, there would be some evidence. Among modern cases in which dementia was alleged to have been feigned is that of *Lady Mordaunt*. (*Mordaunt v. Mordaunt*, Divorce Court, February, 1870.) In consequence of a confession made by this lady soon after her confinement, that she had committed adultery with certain persons, her husband took proceedings against her for a divorce. At the date at which she was served with notice of the writ, the 30th April, 1869, it was alleged that she was insane, and that from mental incapacity she was unfit or unable to instruct an attorney for her defence. On the part of the husband, it was alleged that she was really fit and competent, and that the state of insanity was assumed in order to avoid the exposure of a public trial. ("The Mordaunt Divorce Case, Official Report," 1870, p. 108.) The jury, upon hearing a large amount of evidence from medical experts and others, found that this lady was laboring under "mental disorder," and that she was incompetent to give instructions for her defence.

On the simulation of insanity, see a paper by Dr. Laurent ("Ann. d'Hyg.," 1866, 2, 460). He advises the complete isolation of the person, with daily watching for a certain time, as a method which seldom fails to detect the imposition, while it cannot injure the really insane. One remarkable circumstance he points out, namely, the influence of feigning insanity on the feigner. He is of opinion that persons who have for some days or weeks pretended that they were mad, have become so in the end. In support of this view he quotes the cases of two sailors who had feigned madness in order to escape imprisonment in the hulks. The imposture was at first successful, but in the end it had an unfortunate result, for they became really mad. (Op. cit., p. 462.) An impostor must be ever on the watch that he does not fail on any one point. This creates a great strain on the mind, and as a result of the anxiety attendant on the maintenance of such an imposition at all times and under all circumstances, he may suffer from cerebral exhaustion with its worst consequences.

Appearances after death.—In some cases a medical practitioner may be required to state whether certain appearances found in the brain of a deceased person, do or do not indicate the past existence of insanity or imbecility. Such a question is only likely to arise in chronic cases, in

which the past existence of insanity from oral testimony may be disputed. (Case of *Stulz*, Prerog. Court, 1852.) The appearances commonly met with on an inspection of the head are—thickening of the bones of the skull, close adhesions of the dura mater (the lining membrane), with great congestion of the pia mater, and opacity and thickening of the arachnoid or inner membrane of the brain. There is a general fulness of the bloodvessels of the brain with remains of old cysts, hardened deposits, or even abscesses in various parts of the cerebral substance. Inferences from the existence of these appearances in the brain must however be drawn with caution, because it cannot be said that they necessarily indicate insanity; nevertheless, such chronic changes must be considered as likely to produce greater or less derangement of the mental functions; but the actual degree in which the impairment is alleged to have existed, ought properly to be determined by evidence of the conduct and actions of the deceased during life. In a communication made by the late Dr. Webster to the Medico-Chirurgical Society in April, 1855, there is a statistical summary of the appearances met with in the examination of the bodies of 290 insane patients. In 226 cases, the pia mater was infiltrated; in 207 effusion had taken place in the ventricles; in 184 fulness of the bloodvessels in the brain or membranes was observed; in 117 the arachnoid membrane was thickened and opaque; in 64 the color of the brain appeared changed from its natural hue; in 51 the bloody points (*puncta cruenta*) were large and numerous upon the cut surface of the medullary substance; while in 40 instances blood was effused, sometimes to a considerable extent, within the cranium. This effusion had evidently been the immediate cause of death in most of the patients. From these data it appears that—first, infiltration of the pia mater; secondly, effusion of fluid in the ventricles; and thirdly, fulness of the cranial vessels, are the principal, as also the most frequent diseased alterations of structure, observed in patients who die whilst suffering under symptoms of mental disorder.

As neither the symptoms nor the duration of the insanity is given, it is difficult to apply these results to special instances. In the case of *Roberts v. Kerslake* (Warwich Aut. Ass., 1854), the main question was whether certain appearances in the brain and its membranes did or did not indicate disease of long standing as well as insanity at the particular date at which a will was made. Dr. Conolly and I considered that the appearances were not inconsistent with the supposition that the testator was sane at the time of making his will. ("Journal of Psychological Med.," Oct. 1854, p. 573.)

CHAPTER LXIII.

MEDICO-LEGAL QUESTIONS IN RELATION TO THE INSANE.—APPLICATION OF RESTRAINT.—ILLEGAL IMPOSITION OF RESTRAINT.—VIOLENCE OF TEMPER.—CERTIFICATES OF INSANITY.—RULES FOR THE DISCHARGE OF LUNATICS.

AMONG the questions which may come before a medical jurist in relation to the subject of insanity are the following: A practitioner may be required to say whether a person affected with the malady should or should not be confined in a lunatic asylum,—whether he should be deprived of his civil rights by interdiction, or whether he is so completely cured of his malady as to justify his liberation from confinement. Then again medical evidence may go far to determine whether a will or deed executed by an alleged lunatic should be set aside; whether a marriage-contract or debt should be annulled; and lastly, whether a criminal act was committed by a person while laboring under insanity,—a question involving either the life, or, according to circumstances, the perpetual imprisonment of a person accused of crime.

Application of restraint.—By restraint in a legal sense we are to understand the placing of attendants to watch or control the actions of an alleged lunatic, or his forcible removal from friends or relatives with or without the confinement of his person by physical force. What are the circumstances which will justify a practitioner in applying restraint to the insane? The law has given great power in this respect to members of the medical profession, but, owing to certain abuses, the power has been of late years much restricted by various Acts of the Legislature. Most medico-legal writers agree that we are not justified in ordering restraint except when, *from symptoms* witnessed by ourselves, we have reason to apprehend that *the lunatic will injure himself or others in person or property*. It is then not sufficient to seek merely for evidence of the existence of some *delusion*, but to determine how far that delusion, if present, affects the conduct of the person. The real question is whether we have reason to apprehend *imminent danger*. Unless the delusion is such as to render it probable that the patient or his friends may be injured by his insane conduct, careful superintendence will answer all the purposes of the closest restraint. (For some remarks on this subject, see “Med. Gaz.,” vol. 44, p. 1061.) The act of resorting to restraint on all occasions, has been justified on the principle that it may tend to the cure of a patient by removing his delusion. In this point of view the subject has reference to medical practice and not to legal medicine. It may be urged with more plausibility, that by withholding restraint in incipient cases, mischief may be done by the lunatic to him-

self or others, and that then it will be too late to interfere ; but even here careful superintendence may render close confinement unnecessary.

The legal rule for interference with the liberty of a person, which restraint always implies, may be inferred from the following statement by Sir James Stephen: "There is a normal state in which all human creatures act on the same principles, and the general meaning of sanity is, that the person conducts himself in this normal manner ; that he is acquainted with the circumstances by which he is surrounded ; that he has objects in view in his actions, and that he regulates his conduct with reference to them and to the general considerations which affect matters of that class." ("General View of the Criminal Law of England," pp. 87 *et seq.*) It cannot be too strongly impressed on the mind of a medical man that, before he employs the powers conferred upon him by law, to confine a person who is said to be mad, he should well consider what lawyers imply by the term "madness," in a practical sense. As defined by Sir J. Stephen, it means *conduct* of a certain character—not as it is usually interpreted by medical men, a certain *disease* of the brain the existence of which is speculative, but one of the effects of which, if present, is to produce such conduct. In examining an alleged lunatic, with a view of determining whether he should or should not be placed in confinement, his conduct must therefore be compared with that of other men in a normal state : and here, in order to constitute sane behavior, we must look for a generic and not for a specific resemblance. Any degree of ignorance, vice, or folly is perfectly consistent with sane conduct in a legal sense. The power of restraint is not intended to be applied to such cases as these ; they are properly, under certain circumstances, amenable to the criminal law. An ignorant, vicious, or foolish man may do a great amount of mischief, but he has a liberty of choice and freedom of action ; and if from folly or depravity he selects a bad course, he is not therefore insane, but is as much responsible for his actions as a sane man who prefers a good course. Such a man should not be treated as a lunatic or confined in an asylum under a medical certificate. It may be sometimes difficult to define the line which separates acts of depravity from those of insanity ; but medical men have not been in many cases sufficiently cautious in endeavoring to make a distinction. Lawyers look closely to *conduct* as the chief ground of interference with personal liberty : the conduct must be such as to be inconsistent with the usual behavior of a normally sane person placed under similar circumstances.

In examining a person proposed to be placed under restraint, we must take care not to confound acts depending on *violence of temper* with those which proceed from unsoundness of mind. A man may have always had a violent temper, subject to occasional fits of aggravation ; but this condition must not be mistaken for mental disease. In order to determine whether the acts of a person be due to violent temper or insanity, it will be proper to ascertain what may have been his natural habits. The great feature of insanity is *change of character*—a man who is really insane, is different from what he has previously been ; but it may be proved of a violent-tempered man that he has always been the same. The greatest abuses of the restraint-system have been chiefly observed in

respect to monomania, where persons have been forcibly imprisoned and confined in asylums, because they entertained some absurd delusions, over which, however, they had so great a power of control as to render it somewhat difficult even for a shrewd and experienced examiner to detect them. When at last, after many hours cross-examination, the existence of a delusion has been made apparent, the result has been looked upon as furnishing matter for triumph and exultation ; but, as Dr. Conolly justly remarks, one point in these cases appears to have been wholly lost sight of, namely, What possible injury could have resulted to the patient or his friends from the existence of a delusion over which he had such complete control and mastery as to render it a most laborious task to obtain any evidence whatever of its existence ? (“Indications of Insanity.”) It may be freely admitted that where delusion does exist, there is reason to suppose that the mind must be more or less disordered in all its faculties ; but such patients require only close watching, not a rigorous imprisonment in an asylum. The greatest danger is to be apprehended in those cases in which there is the least power of self-control. The forcible removal of a person from his home to a lunatic asylum, unless the circumstances are of such a nature as to render immediate interference necessary on the ground of admitted or proved insanity, is unjustifiable in law, and may involve those concerned in the removal in a serious responsibility. In cases of incipient insanity such interference would not be legally justifiable, and a practitioner placing restraint on a person so situated, might find himself a defendant in an action for damages.

In *Hill v. Philp* the judges decided that a medical man, when called upon to give a certificate for the confinement of a person, may act upon the directions of a wife, but that the directions must be considered as only guiding his judgment, and not as absolutely dictating to him and justifying his proceedings ; that he is still bound to exercise his own professional knowledge and discretion, so far as to refrain from doing anything or adopting any course which might be injurious to the patient. A medical man is, therefore, ultimately responsible for his treatment of a lunatic : no person can give him authority to do that which is not in accordance with medical practice or the necessity of the case. (For a report of this case, and some judicious remarks upon the decision, see the “Legal Examiner,” May 29, 1852, pp. 307, 318.) In *Scott v. Wakem* (Guildford Summer Ass., 1862), the defendant, a medical practitioner, was sued for damages in placing under restraint, and without necessity or authority, a man laboring under delirium tremens. In this case the wife denied that she had given any authority for interference, and on this point her evidence conflicted with that of the defendant, the medical man whom she had consulted. Fortunately the facts proved were adverse to her statement ; but in future cases of this kind, it would be desirable for a medical man to have a written authority for such proceedings, bearing in mind that he does not exceed what is necessary, proper, or usual for the treatment of the person ; and on this he must always exercise his own judgment, irrespective of the opinions or suggestions of others. Medical men, even when acting most conscientiously in the discharge of their duties, cannot hope to escape harassing and vexa-

tious actions when they are called upon to deal with cases of delirium tremens. The peculiarity of this disorder is that, with the cause, it may soon disappear, and thus medical evidence may be easily procured to show that the person was in a sane state of mind and not in a condition to justify any interference with his personal liberty, either a short time before or after the imposition of restraint.

In order to provide for the protection of lunatics and for the prevention of undue violence or frequency in the application of restraint, the law compels the keepers of asylums to enter in a book a report of each case or of each occasion on which any mechanical restraint is resorted to. An omission to make this entry is a misdemeanor: and at the Maidstone Lent Assizes, 1851, two medical men were convicted and fined for placing patients under restraint without having made the proper entries required by law. (*Reg. v. Maddock*: see also "Med. Gaz.," vol. 47, p. 556; and a paper on the "Use and Abuse of Restraint," in the "Jour. Psychol. Med.," 1849, p. 240.)

Certificates of insanity.—It will here be necessary to state the circumstances which require the attention of a practitioner when he is called upon to sign a certificate of insanity, whereby a person may be placed in confinement in an asylum. The acts which specially refer to this subject are the 16 & 17 Vict., cc. 96 and 97. These acts, which came into operation on the 1st of November, 1853, are a consolidation of the statutes on the regulation of the care and treatment of lunatics. Their provisions are very stringent, both with respect to medical men who sign certificates, and those who keep asylums for the reception of lunatics. According to s. 74, c. 97, no person (not a pauper) can be received into or detained in any asylum without an order from some person (generally the nearest relative) and two medical certificates, which must be signed *by two physicians, surgeons, or apothecaries* not in partnership or an assistant to the other, and each of whom shall *separately from the other* have personally examined the person to whom it relates *not more than seven clear days previously* to the reception of such person into such asylum. These certificates need not be filled up, signed, and dated on the day of examination; but the examination of the patient must be made in every case *within seven clear days* before admission.

It follows that, no certificate is valid if signed (a) by a non-registered practitioner, (b) by the partner or assistant of the person signing the other certificate, (c) by the person who signs the order (for admission), or by his father, brother, son, partner or assistant, and lastly that a certificate becomes invalid and useless, if the reception does not take place within seven clear days from the day of the medical examination on which the certificate is granted.

The following is the form of a medical certificate in the case of private patients:—

I, the undersigned, being a (duly registered) physician or surgeon or apothecary [*here set forth the qualification*], and being in actual practice as such, hereby certify that I, on the day of , at [*here insert the street and number of the house (if any), or other like par-*

ticulars], in the county of _____ etc., separately from any other medical practitioner, personally examined A. B., the person named in the accompanying statement or order, and that the said A. B. is a lunatic [*or an idiot, or a person of unsound mind*], and a proper person to be taken charge of and detained under care and treatment, and that I have formed this opinion upon the following grounds, viz. :—

1. Facts indicating insanity observed by myself [*here state the facts*].
2. Other facts (if any) indicating insanity, communicated to me by others [*here state the information and from whom*].

(Signed)

Name.

Place of abode.

Dated this _____ day of _____, One thousand eight hundred and _____

Under s. 10, c. 96, no person can be received into any registered hospital or licensed house, or as a single patient, under any certificate which purports to be founded only upon facts communicated by others. A medical certificate may be amended if incorrect or defective. No medical man can receive as a boarder in his house any insane person, whether for medical treatment or otherwise, unless he has previously obtained a license from the Commissioners of Lunacy, and one certificate duly signed by two other medical men. The certificate is invalid if signed by the person who takes the charge or who receives a percentage on or is otherwise interested in the payments for the patients. No medical man can receive a single patient into his house on a certificate signed by himself, or by his father, brother, son, partner, or assistant. In January, 1861, a medical practitioner was convicted of misdemeanor for thus receiving illegally a lunatic patient. (*Reg. v. Kelly*, C. C. C., Jan. 29, 1861.) This was a clear breach of the regulations. The defence was that he was ignorant of the law, but this was no answer to the charge. ("Med. Times and Gaz.," Jan. 28, 1861, p. 105; and "Lancet," Feb. 9, 1861, p. 151.)

Dr. Millar, who has had considerable experience as the superintendent of a large lunatic asylum, states that, as a rule, very few of the certificates which are brought with private patients are correctly filled up, notwithstanding the plainness of the instructions. The omission of particulars apparently of no importance has often caused them to be rejected as illegal; and it will therefore be useful to point out the chief errors which, according to this gentleman, are committed by medical men. 1st. A neglect in stating the qualification which empowers the medical practitioner to practice. It is not unusual for the blank space to be filled up with the words "physician," "surgeon," or "apothecary," instead of inserting the *qualification* which enables him to practise in any of those capacities. 2dly. Omitting the address of the house at which the examination was made. If there should be no number to the house, it will be sufficient to state, "At the dwelling-house of _____, in _____ street, village, etc." 3dly. Omitting the address and occupation of the person examined. In nine cases out of ten, according to Dr. Millar, an omission of one of these three simple and obvious particulars, occurs—a degree of carelessness not creditable to the profession. Medical men no doubt err from regarding them as having no bearing whatever on the

sanity or insanity of the patient. (See Millar's "Hints on Insanity," p. 78.)

By s. 13, c. 96, a medical practitioner who gives a false certificate, or any person not being a *registered* physician, surgeon, or apothecary in actual practice, who gives a certificate as such, is declared to be guilty of a misdemeanor. For any act done by a registered medical practitioner contrary to any of the provisions of the Act (although not declared to be a misdemeanor), he is subjected for each proved offence to a penalty of twenty pounds. By s. 36, the words "physician," "surgeon," or "apothecary" shall respectively mean one duly "licensed or registered to practise as such by or as a member of some College, University, Company, or Institution, legally constituted and qualified to grant such authority or license in some part of the *United Kingdom*, or one who was in practice as an apothecary in *England* or *Wales* on or before the 1st day of August, 1815, and being in *actual* practice as such physician, surgeon, or apothecary." (16 and 17 Vict., cap. 96, s. 36.) The certificates of Irish medical practitioners, provided their names are on the register, are valid for the confinement of lunatics examined in England and Wales; and those of registered English practitioners are valid for the reception, in asylums, of lunatics examined in Ireland. A special Act has been passed for Scotland (20 and 21 Vict., c. 71); and by sections 34 and 35, the rules regarding these certificates are similar to those of the English statute.

The Commissioners in Lunacy have issued the following rules for the medical examination of alleged lunatics: "The patient must not be medically examined in the house where he is to remain, nor on the premises. Should he have been living in the house previously to legalizing the charge, the date of admission given in the notice of admission should be that of the day whereon he returns to the house after signature of the order, medical examinations, and signature of the certificates.

"Should it become necessary to obtain fresh certificates, the patient should, as above, be removed for examination. In this case, and where a fresh order has been required, a fresh notice of admission must be transmitted.

"Certificates signed, or founded on medical examinations made, elsewhere than in England or Wales (the extent of the Commissioners' jurisdiction) are not accepted as a valid authority for the detention of a patient within that jurisdiction."

A medical practitioner must not be too ready to lend himself to the signing of certificates for the confinement of persons who may be laboring under harmless delusions. In violent mania, or in monomania with a homicidal or a suicidal propensity, there can be no doubt of the propriety of applying some degree of restraint, for here the necessity is imminent. If a remarkable change has suddenly taken place in the character of a person—if he has become irritable, outrageous, or threatened personal violence to any one—or if he has recklessly endangered the interests of himself and family, he is undoubtedly a fit subject for confinement. (See Pagan, *op. cit.*, p. 75.) The more he approaches to this condition, the less difficulty we shall

have in coming to a decision, and in a really doubtful instance there will be no impropriety in employing temporary restraint; since, although the person is thereby deprived of liberty, it is better that this should happen, than that he or his friends should incur the risk of suffering severely by his insane conduct.

The 74th section of cap. 97 provides that in cases of emergency a person (not a pauper) may, under special circumstances (these being stated in the order), be received into a house or hospital upon a certificate signed by *one* medical practitioner only, provided that within *three days* two other such certificates are signed by two other medical practitioners not being connected with such house or hospital, upon a like examination. The detaining of a person upon one medical certificate only beyond the period of three days, without such further certificates, is a misdemeanor in the keeper of the house or hospital. By s. 67, c. 97, the certificate of *one* medical practitioner only, signed according to the above rules, will suffice for a *pauper lunatic*, provided the person has been previously examined by a justice, clergyman, and overseer or relieving officer. By s. 12, c. 96, no medical practitioner who is interested in, or attends a licensed house or hospital, or whose father, brother, son, partner, or assistant is wholly or partly the proprietor of, or a regular professional attendant in, such house or hospital, shall sign any certificate for the reception of a patient into it. It is obvious from the terms of the Act that one person cannot sign a certificate as a substitute for another, and yet there have been several instances of its violation under these circumstances. In December, 1855, a medical assistant was committed for trial because he had signed the name of the surgeon with whom he was living, to a certificate of insanity for the confinement of a pauper lunatic. There was no doubt about the insanity of the person, and the plea urged in defence was that the surgeon whose name was thus forged, was in ill-health and had given the assistant an authority to sign papers for him. This, however, was no justification for a violation of the terms of the Act; the words of the certificate are so explicit on this point that no reasonable person can have any doubt about their meaning. In *Reg. v. Ogilby*, C. C. C., September, 1872 ("Lancet," 1872, 354, 467, 499), defendant was fined fifty pounds for a breach of the Lunacy Act—*i. e.* for unlawfully signing a medical certificate by representing that he was a *registered* medical practitioner when his name was not on the register. In another case which occurred in December, 1872, proceedings were taken against a medical man under the following circumstances. He signed a certificate for the confinement of a woman really a lunatic, stating that he had seen and personally examined her on the 9th August, 1872, although he had not seen her since March, 1869! Further, it was proved that the certificate was signed on the 10th of September, but dated the 9th of August! The medical man pleaded guilty, and was fined ten pounds by the bench of magistrates. These glaring examples of a departure from the explicit terms of the Act relating to lunatics, should convey a caution to medical men that they cannot with impunity infringe the strict letter of the law.

[The principal hospitals for the insane of the United States have

printed forms and obligations, which are furnished to the friends of patients to be filled up and signed according to the law of the State, and the rules of the hospital. The form of the medical certificate generally requires the patient to have been seen and examined by the physician signing, on the day on which the certificate is dated. In all cases, the certificate is expected to apply only to the actual condition of the patient at the time of signing, and to be used without delay in order to be available.

The medical certificate must always be accompanied by a formal application for admission of the patient, signed by a responsible guardian, near relative, or friend. These papers have also annexed to them a series of questions relating to the past history and existing condition of the patient, the peculiar symptoms of the case, and the probable cause of the attack; which questions are to be answered by the friends and relatives and the attending physician.

Some hospitals require the signatures of two physicians to the medical certificate, neither of them, of course, being connected with the hospitals applied to. The State Lunatic Hospital of New Jersey, beside others, requires the medical certificate to be formally deposed to by two physicians before a magistrate.

Patients sometimes obtain their discharge on a writ of habeas corpus, but are generally removed by friends or discharged, when sufficiently recovered, at the discretion of the superintendent. We are not aware of any legal restriction in this country on the liberation of insane patients, except in cases of homicidal or otherwise dangerous lunatics, who have been confined by order of a magistrate or of a court of law. Such patients can only be released by an authority similar to that which first committed them. There are patients of this class now in durance at the Eastern State Penitentiary of Pennsylvania, and in the different State Asylums.—II.]

As ignorance of the law is not allowed to be an excuse for its violation, so a medical man, unless acquainted with all the particulars above mentioned, may easily subject himself to a prosecution or a civil action; and he is not likely to be spared the disgrace and mortification attendant upon either, should it happen that the case is of a doubtful nature. The law expressly requires from each medical man a separate visit, a separate personal examination of the alleged lunatic, and a separate medical certificate, setting forth the *special fact or facts* (whether observed by himself or derived from the information of others) upon which his opinion is based. Dr. Conolly has shown that there are objections to the severity of the restrictions regarding these certificates ("Journal of Medical Science," April, 1861, p. 127), but some recent cases have proved that they are not even strong enough to prevent sane persons from being wrongfully sent as lunatics to asylums.

Specification of facts.—It will be observed that every medical practitioner signing a certificate of insanity is required to specify the *facts upon which his opinion is formed*, and whether such facts are derived from his own observation or from the information of any other person. Medical men have had some difficulty in performing this duty, *i. e.*, in assigning the fact or facts upon which their judgment of the insanity of

a person was based. ("Med. Gaz.," vol. 36, p. 1434; and vol. 37, p. 485.) What will constitute the description of a fact to render a certificate valid? This important question was raised in the case of *Shuttleworth* (Queen's Bench, Nov. 17, 1847). An application was made for the discharge of a lunatic on the ground that the medical certificates did not set forth the *facts* from which the opinion of those who signed them was derived. In one, the medical man stated that the lunatic (a woman) labored under a *variety of delusions*, and that she was *dirty and indecent in the extreme*; in the other, the certifier stated that he had formed his opinion from the *conversation* which he had that day had with her. It was contended that the statement in the first certificate was not so much a fact as a conclusion drawn from other facts, which ought to have been mentioned in the certificate itself. Lord Denman, in giving the judgment of the court, held that the certificates were valid—that it was not necessary to have all the delusions of an insane person stated in a certificate. The statement that the lunatic was dirty and indecent in the extreme, was *prima facie* sufficient to justify the imputation of insanity, even if the certificate did not state that the patient labored under a variety of delusions. The allegation that the opinion respecting the existence of insanity was founded upon a *conversation* with the alleged lunatic, was also sufficient to render a certificate valid. ("Med. Gaz.," vol. 38, p. 932; also "Law Times," Nov. 21, 1846, p. 145.) They, therefore, refused to allow the discharge of the lunatic. This judgment was given by Lord Denman, and was concurred in by those eminent judges, Mr. Justice Erle, Mr. Justice Wightman, and Mr. Justice Coleridge. The late Mr. Justice Patteson dissented to this extent: he thought a *conversation* had with the lunatic could not be received as the statement of a "fact." The judgment might have been formed upon many sufficient facts, but the surgeon had not condescended to state what those facts were.

This question of the sufficiency of "a conversation to constitute a 'fact'" in drawing up a medical certificate was raised in a case referred to me by Mr. Batteson, a former pupil (September, 1873). This gentleman having duly examined an alleged female lunatic, stated in his certificate as a "fact" indicative of her insanity, "from the conversation I have had with her," following the decision in *Shuttleworth's* case, and using the same language. He quoted a former edition of this work as his authority, but the Commissioners in Lunacy refused to admit this case as a precedent, and required that some fact or facts apart from mere conversation should be distinctly stated. The Lunacy Acts' Amendment Act (25 and 26 Vict., c. 3, 1862, section 37) confers a power on the Commissioners to deal according to their own judgment with medical certificates, and practically to set aside a judicial decision of the Court of Queen's Bench, such as that above given in *Shuttleworth's* case. Thus it is enacted under this statute that, "Where any medical certificate upon which a patient has been received into any asylum, registered hospital, licensed or other house, or either of such certificates is deemed by the Commissioners incorrect or defective, and the same are or is not duly amended to their satisfaction within fourteen days after the reception (by the superintendent or proprietor of such asylum, registered

hospital, or licensed or other house) of a direction in writing from the Commissioners requiring amendment of the same, the Commissioners, or any two of them, may, if they see fit, make an order for the patient's discharge."

It would therefore appear, that in order to satisfy the Commissioners, a medical man must state some "fact," *i. e.*, some act or deed on the part of the alleged lunatic, on which his opinion is based. The Court of Queen's Bench regarded a certificate based on "conversation" only, as a substantial although not a literal compliance with the terms of the Act. Lord Denman thought that it would be monstrous to have all the delusions stated upon the document. Many of them were indecent, and many blasphemous! In spite of this reasonable objection to entering into the details of a "conversation," it is now clear that nothing less than this will satisfy the Commissioners in Lunacy. A medical man, therefore, in drawing up a certificate, should insert those parts of the conversation on which he relies, as well as a statement of any fact or facts in reference to habits or demeanor which, in his judgment, may indicate unsoundness of mind. Dr. Millar has shown how little the words "Facts indicating insanity observed by myself," are appreciated or even understood by many medical men, who are legally empowered as registered members of the profession to sign these certificates. The facts are frequently stated in a loose and careless manner, showing a complete misapprehension of their meaning. What is really required by the law is a statement of facts observed or witnessed by the medical man himself, which would carry conviction to the mind of any non-professional man reading it, that the person to whom the statement referred was of unsound mind. A medical man should in all cases avoid giving as a fact indicating insanity, any delusion which might in reality have some foundation in truth.

With respect to the second requirement of the statute,—namely,—“Other facts (if any) indicating insanity communicated by others,”—it may be observed that, although these do not supersede the facts observed by the medical man himself, they are of great importance in throwing light upon the propensities or habits of the patient, and thus serve as a guide for treatment. (Op. cit., p. 79.) A medical man must take care to draw a clear distinction between the facts observed by himself and the facts communicated to him by others, and avoid such vague expressions as that he “thinks” and “believes,” etc.

As every medical certificate, although accepted by the Commissioners of Lunacy, may become at a future time a subject of close and hostile criticism in a court of law, a medical practitioner should be fully prepared to justify the use of the terms which he has employed. It is therefore desirable that he should studiously avoid any misstatement or exaggeration of the symptoms. One of the facts cited as indicative of insanity in an old lady was that she kept a cockatoo! In the case of *Davies*, the tea dealer, Lord Brougham, then a counsel at the bar, retained to oppose the commission against the alleged lunatic, elicited from one of the witnesses as a fact upon which he relied to indicate insanity, that when asked the question, Mr. Davies, the alleged lunatic, did not know how much money he had in his pocket! Another relied upon the

fact as indicative of a weak mind, that he said he preferred seeing the people returning from Epsom races rather than the racing on the course! Vague and trivial facts, which do not indicate insanity, naturally tend to produce a feeling in the minds of a jury the very reverse of that for which they are brought forward. Thus in this case, although there could be no doubt, from what subsequently occurred, that Mr. Davies was a lunatic, and a fit and proper person to be placed under restraint, yet the eloquence of Lord Brougham, and the result of a skilful cross-examination in bringing into prominence the weakness of the facts on which the medical witnesses relied to establish insanity, had such an influence with the jury that they returned a verdict in favor of the lunatic, and for a time he was considered as the unhappy victim of an unjust persecution on the part of his mother and other relatives! In a case referred to by Dr. Bucknill, one of the medical men certifying to the insanity of a gentleman, who was at that time undoubtedly insane, had stated as facts *observed by himself*, that "his (the patient's) habits were intemperate, and that he had squandered his property in mining speculations." But on cross-examination in the Queen's Bench, he was obliged to confess that the only act of intemperance he had actually observed was the patient's drinking one glass of beer, and that the squandering of property was the loss of what was to him a mere trifle in a mining speculation, which eventually turned out to be a very good one! (Millar's "Hints on Insanity," 1861, p. 187.) Counsel properly hold a medical practitioner strictly to the common and accepted meaning of the words which he uses. If strong points are not forthcoming, the proof of insanity must fail. Weak points generally show a weak case, and should never be brought forward or employed by a prudent witness.

A medical man is not compelled to take upon himself the responsible duty of signing certificates of insanity; but if he does undertake it, he must perform it with reasonable care and ordinary skill. If he certifies that a person is laboring under delusions, he must take care that he understands the meaning of the term, and what are the delusions: and admitting that he is correct in believing from his own observation that they exist in the mind of the patient, it must be remembered that, in order to justify restraint or imprisonment in an asylum, the law looks always to the immediate influence of these delusions upon conduct. In reference to medical responsibility, the following observations were made by a learned judge in the case of *Hall v. Semple* (Q. B., Dec. 1862): "The true ground of complaint is the negligence of the defendant and the want of due care in the discharge of the duty thrown upon him; and I think that if a person assumes the duty of a medical man under this statute, and signs a certificate of insanity which is untrue, without making the proper examination or inquiries which the circumstances of the case would require from a medical man using proper care and skill in such a matter,—if he states that which is untrue, and damage ensues to the party thereby, he is liable to an action, and it is to that I desire to direct your particular attention. In point of law, if a medical man assumes under this statute the duty of signing a certificate, without making that due and proper examination which under such circumstances he ought to make, not in the exercise of the extremest possible care, but

of ordinary care, so that he is guilty of culpable negligence, and damage ensue, then an action will lie against him, although there may have been no improper motive, and the certificate may not be false to his knowledge." In this case the jury found a verdict for the plaintiff,—that the certificate was untrue in effect, and that it had been signed without proper examination and inquiries, and without probable cause.

Discharge of lunatics.—In forming an opinion relative to the propriety of discharging a person who has once been confined as a lunatic in an asylum, it is proper to examine the particulars of his case with the same caution as if the object were to confine him for the first time. Experience shows, in reference to the criminal lunatics confined under State supervision, that there are strong reasons for their detention. In 1877 two men were readmitted, after their discharge as cured, on account of their having repeated the offences of which they had been previously convicted. The question of liberation is commonly restricted, like that of restraint, to cases of mania and monomania. It may so happen that the person has a lucid interval at the time of examination, in which case it will be necessary to make more than one visit. One who has been guilty of a heinous crime like murder, should never on any pretence be discharged. There are often long lucid intervals in homicidal mania, and it is impossible to be certain that the disease is entirely removed. Instances have occurred in which persons who had been confined on account of acts of murder, and liberated on apparent recovery, have, soon after their liberation, murdered a wife or child, and have been again tried and sent to an asylum. Yet it appears to be the custom at Broadmoor to discharge, on their apparent recovery, patients who have been guilty of murder. In 1877, one man and three women who had committed murder, were discharged and sent to their friends. The man had killed his son, and the women their children. They had been acquitted on the ground of insanity, and had apparently recovered.

A quiet and orderly manner maintained for many weeks or months, may suffice to throw both physician and attendant off their guard. Dr. Orange relates a case in which a man was tried and convicted of murder in 1868. He became insane, and was admitted into Broadmoor in 1869. For eighteen months he conducted himself with such propriety, that he was allowed to go for walks with his attendant. One day, while thus walking, apparently quite restored, he asked his attendant a question about some rabbit burrows near the path. The attendant stooped down to examine one of them, when in an instant he was felled to the ground by a heavy blow on the back of his head. The lunatic then attempted to strangle him, and ultimately escaped. The attendant had concussion of the brain, and suffered for many weeks. This case shows how easily those who are accustomed to lunatics may be deceived and thrown off their guard.

If the lunatic has manifested the least disposition to suicide, we should be extremely cautious in liberating him; for suicidal mania is often artfully concealed under a cheerful exterior. We cannot always test the propriety of granting liberation by the lightness of the offence for which a criminal lunatic has been confined. The circumstances under which

the most trifling offence has been committed, may show that the mind is wholly unsettled with regard to moral responsibility ; and such lunatics can never be trusted, even when there is a great improvement in their language and deportment. In this respect the case of the *Rev. H. J. Dodwell* (C. C. C., March, 1878), is of some interest. This gentleman discharged a pistol, in open court, at the Master of the Rolls. The motive which he assigned for the act was to draw attention to his case (a chancery suit), and to have it brought fully before the public. He was tried for the offence, and acquitted by the jury on the ground of insanity. The result was, that he was consigned as a lunatic to the criminal asylum at Broadmoor. The court and jury thought that the act of the accused showed a total absence of self-control, and that the motive assigned was irrational, and not consistent with soundness of mind. It was not considered necessary at the trial to require medical evidence of the state of mind of the prisoner. Like all real lunatics, he strongly denied that he was insane.

Had medical evidence been called, it is clear, from what followed, that there would have been the usual conflict of opinion. Some physicians would have pronounced him sane, and others insane and irresponsible. This would have only confused the jury.

Soon after his acquittal and confinement in Broadmoor, Mr. Dodwell was seen on the part of his friends, by two physicians. Their opinion was that he was quite sane, and ought to be discharged ; in fact, that he was a sane man, "incarcerated in a living tomb." The interests of the public do not appear to have been represented on this occasion. The prisoner was subsequently visited and examined by two other physicians, under an order from the Secretary of State, and three months afterwards by two independent medical gentlemen appointed by the Commissioners of Lunacy. The result of their interviews with the reverend gentleman was that he was decidedly insane, and it would be unsafe to allow him to leave the prison. The discharge of Mr. Dodwell might have simply led, as in other cases, to a repetition of the heinous crime of which he was guilty.

The 16th and 17th of Victoria, c. 97, has placed certain restrictions on the power of liberating lunatics. Under ss. 83 and 84, the person originally signing the order which is required in addition to the medical certificates, may write an order for discharge or removal ; but under s. 85 this order is of no effect, if a medical practitioner certify that in his opinion such patient is dangerous and unfit to be at large, together with the grounds on which his opinion is founded, unless the Commissioners or Visitors shall, after the production of such certificate, give their consent in writing for the removal or discharge of such patient. Under other clauses, additional powers of discharge are given to the Commissioners and Visitors, subject to such restrictions as to leave the control for the most part in the hands of professional men. These powers of discharge do not, however, apply either to criminal lunatics, or to those found insane under a commission issued by the Lord Chancellor.

CHAPTER LXIV.

LUNATICS AS WITNESSES.—INTERDICTION.—COMMISSIONS OF LUNACY.—
EXAMINATION OF ALLEGED LUNATICS.—MEDICAL AND LEGAL TESTS OF
COMPETENCY.—CONFLICT OF EVIDENCE AND OPINION.

Lunatics as witnesses.—In regard to the testimonial capacity of lunatics, it may now be considered as settled, that a lunatic who labors under delusions, but who in the judgment of a medical practitioner is capable of giving a fair account of any transaction that happened before his eyes, and who appears to understand the obligation of an oath, may be called as a witness. (*Reg. v. Hill*, “Denison’s Crown Cases,” 2, p. 254.) The rule first laid down by Baron Parke is in accordance with this view: it is for the judge to say whether the evidence of the witness is admissible, and then his credibility is a question for the jury.

Lunatics occasionally bring actions for damages, involving charges of assault against those in whose establishments they may have been confined. A recent trial in the Exchequer Division (*Nunn v. Hemming*, Feb. 1879), shows how such cases are dealt with, and proves that, unless the testimony of a lunatic is corroborated, it will not be accepted by a jury. The plaintiff claimed damages from the defendant, Dr. Hemming, for an assault while under his care as a lunatic patient. He had made an attempt to escape, was brought back to the asylum, and was, according to his statement, violently plunged into a cold bath and nearly drowned. No complaint was made of this treatment by him to the commissioners until three years after the occurrence. In letters to his wife shortly after the alleged maltreatment, he had not mentioned it. The story of the plaintiff was directly contradicted by every living man who could have witnessed the scene if it had occurred, and there was no confirmatory or corroborative evidence. On the other hand, seven medical men had testified that the plaintiff at this time, and subsequently, had labored under delusions, and had attempted suicide. The plaintiff admitted in court that he had swallowed his three shirt-studs, because he thought that, being gold, they would cure a pain in the stomach! His counsel contended that his statement was to be believed, and those who testified against him he treated as perjured witnesses. His contention was, “Get rid of the plaintiff’s delusion and the facts are proved,” but this was precisely what could not be done, and after a five days’ trial the jury at once returned a verdict for the defendant. Any other conclusion would have been against justice and common sense. This case shows that the uncorroborated testimony of a lunatic laboring under insane delusions will not be accepted as evidence.

Interdiction.—By interdiction we are to understand the depriving of a person laboring under mental disorder of his civil rights; in other

words, preventing him from exercising any control or management over his affairs. It may be with or without restraint, for one condition does not necessarily imply the other, although there is a popular idea to the contrary. In *Re Smith* (June, 1862) an order for a jury was issued to try the question of sanity or insanity, and in affirming the order, Lord Justice Knight Bruce made the following statement: "It is desirable to remove the idea, but too generally entertained by persons (common persons) in different stations of life, that the finding by a jury that a person is of unsound mind necessarily involves an interference with his personal freedom; it does not. The court places no further restraint upon a lunatic than is necessary for his protection, and I would refer to the fact that there are several lunatics living under the protection of the court, who reside in their own houses with large establishments."

When a person, from mental incompetency, is liable to be imposed upon by others, or is guilty of foolish and extravagant acts, whereby his property is wasted, a commission is commonly granted by the Court of Chancery, in order to determine whether he be "*compos*" or "*non compos mentis*." This writ is well known under the name of "*de lunatico inquirendo*." Before it can be issued it is necessary, among other matters, that there should be affidavits made by two or three physicians or surgeons, certifying to the insanity of the person. It has been already explained that the object of the commission is to determine whether the incapacity to manage affairs is owing to some *mental* defect or disorder, and not merely to want of education or bodily infirmity—otherwise all wealthy minors and infirm persons might be improperly deprived of the control of their property. Formerly commissions were not issued unless it was evident that lunacy or idiocy existed—for weakness of mind or imbecility was not considered sufficient to justify legal interference. This is no longer the case, "unsoundness of mind with incompetency" being all that the law requires to be established. Thus then, whether the case be one of mania, monomania, or dementia is not now the question, but whether the party be *compos* or *non compos mentis*: if the latter, whether it be to a degree to prevent him from controlling his property with careful and provident management. There was a strange contradiction in our system of jurisprudence some years ago. A person who had a delusion on a particular subject, although not affecting his social duties, was deemed a fit subject for a commission, and deprived of his civil rights merely because his mental disorder would fall under the definition of lunacy. On the other hand, one who had no delusion, but great mental weakness, such as to incapacitate him for properly managing his affairs, was not deemed a fit subject for a commission; since weakness of mind and insanity were considered to be two entirely different states—the latter alone requiring interference, although the injurious results might be the same in both cases.

It is unfortunate that these commissions have been usually conducted on so expensive a scale as to render them applicable only to the wealthy classes of society: and even here the expenses attending such a simple inquiry as that for which the commission is issued, have been often of the most ruinous kind, and the results by no means satisfactory. The Lord Chancellor has it now in his power to direct an inquiry to be made

before one or two commissioners, in which case a jury is dispensed with. Evidence may then be received, and the decision left with the commission or commissioners so appointed. The cost of an inquiry by this regulation are greatly reduced; but even under the amended law, no Commission of Lunacy can be had at a less expense than 60*l.*, and this only in uncontested cases. This form of proceeding is now adopted in the greater number of cases, so that out of 575 commissions in ten years only 21 were before juries. The Lunacy Regulation Acts are the 16th & 17th Vict., c. 70 (1853), and the 25th & 26th Vict., c. 86 (August, 1862). The last-mentioned act has greatly improved proceedings in lunacy, and has removed much of the injustice which formerly prevailed. In order to shorten these inquiries and lessen the expenses, the order under s. 3 is to be confined to the question whether or not the person is "at the time of unsound mind and incapable of managing himself and his affairs." No evidence on his conduct is to be received as a proof of insanity unless it refers to a period within *two years* of the date of the inquiry. In cases of contested imbecility, this provision might exclude important evidence, but there is a discretionary power in the judge to admit it. Section 4 allows of a case being tried by a jury at common-law. The alleged lunatic is to be examined before the taking of the evidence, as well as at the close of the proceedings before the jury consult on their verdict. Under s. 12, power is given to the Chancellor to dispense with commissions in reference to persons who have but small property; and there are in this statute other strict rules regarding the visiting of lunatics confined in asylums.

One source of difficulty on these occasions is that medical witnesses are allowed to be separately sought out and summoned by those who are for and against the commission, and the opinions given by them often exactly neutralize each other. Under these circumstances they are converted into partisans in the cause, as much as if they were counsel. It has been well remarked that a man, even unknown to himself, with the purest intentions and the most perfect rectitude, will insensibly lean to the side on which he has been consulted or employed. (Pagan, p. 301.) The public are apt to infer from such conflicting opinions emanating from men of equal experience, that the difference cannot depend essentially on the *medical* facts of a case, and that the question might be as well or even better determined by non-professional persons. See the case of *Mrs. Cumming* ("Journal of Psychological Medicine" for April, 1852), in which the conflict of medical testimony was even greater than usual. A large portion of this lady's property was spent in determining by a verdict that she was insane; and there was an intention that the remainder should be expended in reversing the decision, when the unfortunate lady died!

One remedy for this serious evil would be that medical experts on such occasions should be selected and appointed by the Lord Chancellor to examine an alleged lunatic and give evidence on his condition; they should be in all cases made perfectly independent of both parties. At present they rather occupy the position of medical counsel than medical witnesses, for it is quite clear that no one would be summoned whose views did not coincide with those of the party summoning him; and it is

an opinion among some solicitors—for which, unfortunately, there is apparent reason—that medical evidence on these occasions is a marketable commodity, and may be purchased at graduated prices! There are some medical men who appear to think that on these occasions they are justified in sinking the witness in the advocate, and that they are bound by a sort of duty to make the best of the case for the person who retains them: but this is a mistaken view of their position. An advocate is not bound by an oath to state “the truth, the whole truth, and nothing but the truth;” but a scientific witness is placed under this sacred obligation, and it is a duty which he owes to his profession and to society that he should lay aside all personal bias. It may appear an innocent matter to suppress some facts and to exaggerate the importance of others, in order to induce a jury to pronounce one whose mental soundness is in question to be perfectly sane and competent; but the same mercenary zeal which would thus lead to the civil freedom of an insane person, might on another occasion be employed in unjustly depriving a sane person of his liberty. The confidence of the public in medical opinions in reference to the insane, has been by recent events already much shaken; and it would be altogether destroyed, and such opinions entirely dispensed with, if it were once known that a medical man on these occasions accepted a retaining fee not to speak the whole truth, but, rightly or wrongly, to give his evidence in favor of the party who consulted him. Whatever may be the difficulties of the case, experienced solicitors know that if they only search far enough they will generally fall upon some medical men who will adopt their views. (The reader will find some remarks on this subject in the “Medical Gazette,” vol. 5, p. 719; vol. 11, p. 740; and vol. 17, p. 816.)

Examination of alleged lunatics.—To determine whether a person is or is not a fit subject for interdiction or deprivation of civil rights, it is necessary to bear in mind that it is not enough to show there is *delusion*, as in the lighter cases of monomania; but we are bound to ascertain how far the delusion affects the judgment of the person, so as to prevent him, like other men, from managing his affairs with provident care and propriety. In many instances, however, some proof of *delusion* only is sought for; and, if this be procured, it is hastily inferred that the person must be entirely incompetent to manage his property. The most difficult cases are those which involve questions of imbecility. In conducting the defence of the *Windham* case (Dec. 1861), Sir Hugh Cairns was allowed by his medical advisers to make the following strange statement: “In a case of insanity accompanied by delusions, the mode of investigating it so as to arrive at the truth is a matter of great difficulty and doubt; but in a case of imbecility, where there is either no mind at all or next to none, the task of coming to a right and just decision is comparatively easy.” Such a statement is the reverse of the truth, and must have been made under some hazy notion that the state of imbecility was identical with that of idiocy. One of his own witnesses (Dr. Sutherland), in a subsequent stage of the proceedings, corrected this error, by the admission in cross-examination, that “drawing the line between soundness and unsoundness of mind in cases of imbecility, is one of the most difficult questions of medical science.”

In conducting the examination of an alleged lunatic, we should compare his mind as it is with what it is proved to have been; and if it be a case of supposed imbecility, a proper regard must be had to age, society, education, and general conduct. We should also consider whether the person has been treated by his friends and relations as a lunatic or imbecile prior to the issuing of the commission. A young person whose education has been much neglected, and who has never been entrusted with the care of money, cannot be expected to have much knowledge of the method of managing a large property. Questions are sometimes put on the moral responsibility of man and the attributes of God, to one who, perhaps, never heard of ethics or metaphysics. Again, mathematical and arithmetical questions, which would embarrass many persons who are set down as sane and competent, are sometimes put on these occasions. In one instance a learned physician gave evidence on a commission that he found the alleged imbecile could not work the first proposition in Euclid, but this person admitted that he had always disliked mathematics. In a case which occurred in Scotland, one examiner asked the alleged imbecile, who said he had 1200*l.* in the bank, and received 20*l.* for interest, How much was that per cent. ? He said he could not tell: he was no good hand at arithmetic. The counsel who appeared against the bribe or commission afterwards put the same arithmetical question to one of the medical witnesses who had deposed to the imbecility of the party; and this witness, an educated man, confessed himself quite unable to answer it—a practical illustration of the impropriety of pronouncing a person to be imbecile or incompetent merely because he is ignorant of that which he has never been taught! (Case of *David Yoolow.*) If the capacity to manage affairs rested solely upon a knowledge of arithmetic, many now go free who ought to be immediately placed under interdiction. This is rather a commercial test of insanity: but it will be found that it has been applied in a very improper manner to determine the capacity of young and ill-educated women. Unless the questions are confined to those subjects which the person has had either the opportunity or inclination to learn, a medical witness will always incur the risk of confounding mere ignorance with imbecility.

One of the best tests of mental capacity will be found in determining the degree to which, with ordinary opportunities, a person has shown himself capable of being instructed; but too high a standard must not be assumed as a test of capacity. The mind of an alleged imbecile should not be compared with the most perfect mind, but with that of another person of average capacity, of the same age and station in society, and who has enjoyed like opportunities of instruction. It would be difficult to find two sane persons who were exactly equal in mental power: in some, one faculty is prominently developed, in others another. All that we have to look for in these cases of alleged unsoundness is an average degree of intellectual development, so as to qualify the person for performing the duties of his station. To win the confidence of an alleged lunatic for the purpose of examination, we should not treat his observations or delusions with levity, but rather seriously sympathize with him in his troubles; we should listen attentively to all he has to say, for his suspicions will be excited by many questions being put to him. If we

cannot agree with his conclusions, we should not contradict him abruptly, but endeavor to draw him out by asking for some corroborative evidence of his statement. Dr. Millar has properly advised that, before visiting the patient, we should make ourselves thoroughly acquainted with every particular connected with his history and condition, and treat him as much like a sane person as possible. The insane are exceedingly suspicious, and quick to detect any deceit practised on them. They are also jealous of the intrusion of strangers, and, unless great tact is employed, will look upon a medical man as an enemy. ("Hints on Insanity," p. 58.) The patient should be informed that his perceptions are merely the result of natural disease; it is useless to tell him that he is under a delusion when his perceptions, although sometimes exaggerated, are too real to be doubted. (Op. cit., p. 36.)

The conflicting medical evidence given on Commissions of Lunacy is in great part to be ascribed to the fact, that the whole of the mind of the person is not fairly examined. One physician tests one faculty, another, another; each has his own theory of insanity, and each his own standard of competency. The witnesses in support of the commission do not go so much to test the actual state of mind of the person, as to discover what they deem proofs of insanity: those against the commission take an opposite course—they look only for some proofs of soundness. It cannot, therefore, happen otherwise than that different conclusions should be drawn under such different modes of investigation. There is another point which requires attention in these cases. Persons laboring under a slight degree of imbecility are very soon irritated; they are easily persuaded that they are ill-used and persecuted; and when they happen to be questioned by parties who are represented as their enemies, they lose their self-command, and are no longer able to answer questions which under their ordinary state of mind they would reply to with perfect accuracy. (Pagan, op. cit., p. 302.) A defective memory must not be hastily set down as a proof of legal unsoundness. This is more or less the natural result of age. A man may not have a good memory, and yet have a mind sound enough for the management of his affairs. A defective memory in an aged person, taken alone, proves nothing. (See "Ann. d'Hyg.," 1836, vol. 1, p. 192.)

A medical witness must not allow himself to be embarrassed by medical or legal definitions of insanity. The malady may not assume the form of lunacy or idiocy, in a strictly legal view—nor of mania, monomania, dementia, or idiocy, in a strictly medical view; but still may be a case of *such mental disorder* as to create an *incapacity for managing affairs*. This is the point to which a medical examiner has to direct his attention. Cases of imbecility present the greatest difficulty, and create the greatest conflict of opinion among medical witnesses. Imbecility strictly implies a weak or feeble mind, and this term is properly applied to one who has an intellect below par or below the normal average. The vagueness of these terms shows how difficult it is to draw a clear distinction between legal sanity and that degree of mental weakness implied by imbecility which would justify interdiction. Insanity in the common acceptation of the term cannot be proved in these cases: there will be no evidence of delusion, and there may be such an amount of self-control as to enable a

person to maintain a rational conversation. Memory, judgment, and other faculties, although weak, are still present in a greater or less degree; and from one or two interviews only, an examiner might be disposed to pronounce the person of sound mind and competent to manage his own affairs. There is a wide field for argument here; for it may be said with some truth in a defence, "that the doctors cannot put their fingers on a single point indicative of insanity." In short, each fact specified by them may be frittered away with the remark that every one must have known some person who had either a bad memory or a weak judgment; who squandered money, who wasted it on unworthy objects, who hoarded it and refused to pay just debts, or who lost it in foolish speculations, etc. All this may be true, and yet the person in question may be legally of unsound mind and properly interdicted. As Dr. Pagan justly remarks, there is a facility of disposition in an imbecile or weak-minded person, which lays him open to be imposed upon by the artful and designing; and our conclusion regarding his competency must therefore be the result of a just appreciation of his general knowledge of affairs, derived from an examination of *all* his faculties. We have to consider how far his imperfect mind would prevent him from attending to his own interests, not in a manner which would insure their most profitable application, but in such a way as would prevent his affairs from being involved in ruin. His knowledge and understanding may be so imperfect that his property would necessarily run to waste under his unassisted control. When it is proved that there has been habitual submission to the dictation of others, either from a long habit of being controlled, from indifference, or fear—when a man has allowed himself to be disobeyed or neglected by his servants, and to be openly cheated by tradesmen—these circumstances furnish evidence of weakness of mind, and a justification of the opinion that there should be interdiction. (Op. cit., p. 293.) On the other hand, if a person when left to himself has managed his affairs with reasonable care and propriety, and has acted independently of others, there can be no stronger proof of his legal competency. [See the very able opinion of Patton, P. J., in *McElroy's* case, 6 W. & S. 451.—P.]

The testamentary capacity of imbeciles may be tried by the same rules. A man who is of such an easy disposition as to be improperly influenced in the use of his property while living, may be equally influenced by fear or control to make an improper disposition of it by his will; but in this case the terms of the will, if drawn up by himself, will allow a fair judgment to be formed of the mental soundness of the testator. There is on these occasions a method of testing the state of mind which has been suggested by Dr. Connolly—namely, by inducing the patient to express his thoughts in writing, as in a letter addressed either to his physician or to some confidential friend. This plan would probably often succeed in developing the existence of a latent delusion, when an oral examination would wholly fail; the patient would not be led to suspect that he was being subjected to an examination for a hostile purpose. The current of his thoughts would be uninfluenced by the suspicion that the act of writing was to test the state of his mind; and as no man can long write in a connected manner who does not think collectedly, so we may expect to find ample evidence whether a delusion really exists

in his mind or not. There are cases recorded in which the evidence of delusion has been derived from the terms of a will or deed written or dictated by the lunatic himself, when there was great difficulty in obtaining proof by an oral examination.

In idiocy there is no capacity for writing. In dementia, as there is no memory, it commonly happens that the same word is written over and over again. No person in a state of dementia can write a connected sentence, because before the last part of the sentence is completed the first is entirely forgotten. In imbecility we may meet with every variety of mental defect, but the state of the mind is generally well shown by the expression of the thoughts in writing. This method, it must be remembered, cannot show whether or not a person is capable of managing his affairs: it is a mere index of a certain state of mind, and must be coupled with general habits and conduct before any conclusion is drawn from it relative to the propriety of interdiction. It will often serve to detect the existence of a delusion when other means fail. Dr. Forbes Winslow attaches some importance to handwriting as foreshadowing the occurrence of general paralysis with softening of the brain. This, however, refers not so much to composition or style as to correct writing and spelling. (Op. cit., p. 464.) The reader will find a complete essay on the writings of the insane, and the medico-legal conclusions to which they lead, by Dr. Marcé, in the "Ann. d'Hyg. Publique," 1864, vol. 1, p. 379. When a verdict of insanity is returned under a commission, it must always represent the person to be of unsound mind, and by reason of that unsoundness to be incompetent to manage his affairs. A date must be fixed at which the insanity first appeared, and this date should always be anterior to the issuing of the commission. If there are lucid intervals, the space of time occupied by these should also be defined.

Among modern cases well calculated to show the conflict of medical evidence on commissions of lunacy, is that of the late *Mr. W. F. Windham* (December, 1861). Fifteen of the relatives of this gentleman petitioned for an inquiry into his state of mind, on the ground that he labored under congenital deficiency of intellect (imbecility), and this view was supported by strong medical opinions; on the other side it was alleged that the mental condition of Mr. Windham, if below the normal standard, was merely the result of a neglected education. The inquiry lasted thirty-three days, during which 140 witnesses were examined—namely, fifty on the part of the petitioners, and ninety in favor of Mr. Windham, at a cost of about £30,000. There was no proof of the want of opportunity of education, but strong reason to believe that the alleged imbecile had not, like other boys of his age, made use of the advantages which he had enjoyed. He had been sent to Eton, but had derived little benefit from his connection with that great public school. It seems to have been admitted that, as a boy, he was wholly unlike other boys, and when he attained his majority, in August, 1861, his conduct was extravagant, wild, and quite inconsistent with his social position. At the same time, he was not entirely deficient in business matters; for it was proved that his uncle, one of the petitioners, had shortly before negotiated with him for the sale of a piece of land of the value of £1000, thereby admitting

his capacity to transact business. The evidence received on this occasion was allowed to extend to the whole of his life, and it may be observed that in cases of alleged imbecility it is not possible, without doing injustice, to prevent the reception of evidence from a long antecedent date. The result of this inquiry was that the jury, by a majority of fifteen to eight, returned the following verdict—"That Mr. Windham is of sound mind and capable of taking care of himself and his affairs." After the verdict had been returned pronouncing him sane and competent, he was guilty of many extravagant acts, exhausted a splendid fortune, and became a bankrupt; showing that, whatever legal soundness of mind he might possess in the opinion of two-thirds of the jury, he practically did not evince the capacity which by their verdict they declared him to possess, of taking care of himself and his affairs!

A large section of the public joined in the view prominently put forward at this inquiry by his counsel, Lord Cairns, that this unfortunate young man had been made the victim of a charge, the most cruel, unjust, and unjustifiable! Insanity, it was urged, in the ordinary acceptance of the word, did not exist in his case. There were no illusions, hallucinations, or delusions; but as these are never met with in the form of unsoundness imputed to Mr. Windham, namely imbecility, their absence proved nothing for or against the existence of imbecility or weakness of mind. But what test is there for imbecility except conduct and conversation? There was no incoherency of language, but there was strong evidence of habits such as we do not meet with among men of really reasonable minds; but opinions were divided on the question, whether these indicated unsoundness of mind, or a mixture of eccentricity and moral depravity from deficient education. A majority of the jury took the latter view; and Lord Chelmsford, in commenting upon this verdict in the House of Lords (March 1862) said:—"The law as laid down by Lord Lyndhurst, applied to cases short of insanity, but they must be cases of unsoundness of mind; and mere extravagance or follies, which indicate imbecility, would not be sufficient unless the imbecility amounted to unsoundness of mind." The legal test of the existence of this state of mind, we are told by high authority, is "conduct." A lawyer means by madness "conduct of a certain character," while a physician means by it "a certain disease, one of the effects of which is to produce such conduct." ("Crim. Law of England," by Sir Fitzjames Stephen, p. 87.) The whole evidence against Mr. Windham bore upon conduct, and from the verdict we learn what sort of conduct does *not* constitute unsoundness in a legal sense. Thus the marrying of a woman of disreputable character,—the squandering upon her of 14,000*l.* in jewelry, and settling upon her without any reasonable grounds, 800*l.* per annum, with other extravagant acts of a similar kind, do not constitute "conduct of a certain character" sufficient to render a man *non compos mentis* in the eye of the law; but if these acts evince soundness of mind and a competency to manage affairs, what are the acts which indicate unsoundness or incompetency? On the other hand, we are told that the physician looks to the existence of a certain disease; but a physician can know nothing about the existence of disease of the brain during life in any case of imbecility, except in so far that its effects

which the alleged lunatic or habitual drunkard resides. There may be one or three commissioners, who are to "diligently inquire, by the oaths or affidavits of six good and lawful men of the county," whether the party is a lunatic, etc., how long he has been so, whether he has lucid intervals, what property he owns and its value, etc. etc.; and "the inquisition so to be made" to return to the court at a time specified in the commission. The act (§ 67) defines the word "lunatic" as meaning "any person of unsound mind whether he may have been such from his nativity, as idiots, or have become such from any cause whatever." By § 63, it is provided that upon petition of the party setting forth that he is restored to a sound state of mind, the court shall take proof of the facts, and if satisfied of the truth of the allegations of the petition, shall suspend, or as the court shall decide, altogether supersede and determine the commission, the inquisition, appointment of a committee, and all subsequent proceedings.

Though, in the main, governed by the principles applicable to similar proceedings in the Court of Chancery, the provisions of this act are much simpler and less expensive.

Where there is a traverse of the inquisition, the question is not simply whether unsoundness of mind exists, but whether it exists to such an extent as to disqualify the traverser from conducting himself with personal safety to himself or others, or from managing and disposing of his own affairs and discharging his relative duties. *Mc Elroy's case*, 6 W. & S. 451. The great object of the proceedings under a commission of lunacy is to afford security and protection. The fact that, as yet, the lunatic may not have squandered his property is no security that he may not do it hereafter. The act is precautionary in its design, and hence a disposition of mind or body, which might lead to the wasting of an estate is sufficient to justify the enforcement of its provisions. *Ib.*; *Sill v. McKnight*, 7 W. & S. 245; *Ludwick v. Commonwealth*, 6 Harris 175.

The same act (13th June, 1836) §§ 58-62, introduces the provisions of 39 and 40 Geo. III. c. 94, relative to the subject of *criminal* proceedings against persons who were lunatics at the time of the commission of the offence, or who have become so since. These sections have been re-enacted by the new criminal code of 31st March, 1860. They provide that when a jury shall acquit any person charged with crime or misdemeanor, on the ground of insanity at the time of the commission of the offence, or when he shall be found to be a lunatic upon arraignment, such jury shall find specially the fact of insanity and declare in their verdict that this was the ground of acquittal. The court may then order him to be kept in strict custody, so long as he shall remain of unsound mind, or he may be delivered to his friends, or to the guardians of the poor upon the entry of security that he shall be restrained by seclusion, or otherwise, from the commission of any offence. When the prosecutor fails to appear, and the prisoner would be otherwise discharged, if it appear to the court upon affidavit of any credible person that the defendant is insane, the court are required to order the district attorney to send a written allegation of such insanity to the grand jury, who shall make presentment of their finding to the court; and thereupon a jury shall be impanelled to try the insanity of such person.

Similar statutory provisions exist in Massachusetts and Minnesota, and perhaps in other States of the Union. See *Bonfanti v. State*, 2 Min. 123.

The criminal courts of Pennsylvania may also upon petition inquire into the insanity of, and commit to the State Lunatic Asylum persons unsafe to be at large, and those who are suffering unnecessary hardship of duress; Act of 14th April, 1845. This application may be made by a married woman. *Shenango v. Wayne*, 10 Casey 184. See also Brightly's Purdon's Dig., tit. "State Lunatic Asylum." Id., tit. "Lunatics and Habitual Drunkards." The act of 1845 also gives the officers of the poor authority to send insane paupers to the State Asylum.

These acts of course do not prevent the sending of persons to asylums by their friends, without the intervention of the courts. All such cases may, however, be brought before the courts upon *habeas corpus*. See Dr. Hartshorne's note, ante, p. 802. See also the case of *Hinchman v. Ritchie*, Bright. R. 144.—P.]

CHAPTER LXV.

CIVIL RESPONSIBILITY.—TESTAMENTARY CAPACITY.—WILLS MADE BY THE INSANE.—TEST OF CAPACITY.—EVIDENCE OF DELUSION.—ECCENTRICITY IN WILLS.

Responsibility in civil cases. Insanity as an impediment to marriage.—Insanity is deemed in law to be a civil impediment to marriage, because it is considered that there cannot be that rational consent which is necessary to the validity of a contract. The marriage of a lunatic is therefore called a nullity, and is void *ab initio*. All that the law requires is that there should be good proof of insanity at, or about the time of the contract. If this be offered, and it be alleged that the contract was entered into during a lucid interval, then the party who would benefit by the allegation must prove it. The suitableness of the marriage, as well as the conduct of the party during or after its performance, will also be considered by the court. In *Turner v. Myers*, a lunatic who had recovered from his lunacy instituted a suit to set aside a marriage which he had contracted while in that state! The marriage was declared void. ("Med. Gaz.," vol. viii. p. 481.) The case of *Baldry v. Ellis* (Norwich Summer Ass., 1851) will be found of interest in relation to the matrimonial engagements of alleged lunatics.

[But though marriage with an idiot or lunatic be absolutely void, and no sentence of avoidancy be absolutely necessary (*Browning v. Peane*, 2 Phillimore, 1969), yet, as well for the sake of the good order of society, as for the peace of mind of all persons concerned, it is expedient that the nullity of the marriage should be ascertained and declared by the decree of a court of competent jurisdiction. 2 Kent, Com. 76.—P.]

In *Reed v. Legard* (Court of Exchequer, May 30, 1851), a question

arose whether a lunatic was responsible for necessities supplied to the wife. The articles supplied were for the sole use of the wife, the husband being a confirmed lunatic, and the inmate of an asylum. The court held that the fact of a husband being from the visitation of God unable to manage his affairs, did not absolve him from the obligation which he contracted when he married, to provide necessities for the support of his wife. He was then of sane mind, and although he had subsequently become insane, that obligation was not revocable under the circumstances. (See also a report of the case of *Seaton v. Adcock*, "Journ. Psychol. Med.," 1851, p. 297.)

The validity of civil contracts entered into by lunatics will depend mainly on the circumstances which accompany the act. If there be nothing unreasonable in the conduct of the lunatic, and the party with whom he contracts has no knowledge or suspicion of the insanity, then the contract will be binding on the lunatic and his representatives. It was so held in *Monckton v. Cameraux* (Exchequer, June, 1848). This was an action by the administrator of a deceased person, to recover from the defendant, as secretary of an insurance office, the sum paid by him as the consideration for two annuities, the foundation of the action being, that at the time of the arrangement in question the deceased was not in a sound state of mind. At the trial before the Chief Baron it appeared that the negotiation had been conducted by the deceased with apparent prudence, insanity, and judgment, and that the arrangement entered into by him with the office was just such as any ordinary prudent person would have been expected to make with a view to his own interest. The deceased, who died very soon after the business had been arranged, was, both before and after, in an unsound state of mind. Under these circumstances, this action was brought by his representatives, and a verdict recovered by them, subject to the opinion of the court on their right to recover as on the entire failure of consideration. The Chief Baron, in giving judgment in favor of the defendant, said it was sufficient for the purpose of this case to lay it down as a general rule, that when a person of apparently sound intellect enters into a contract such as any other ordinary person would enter into with others who act *bonâ fide*, and the parties cannot be restored to their former condition, it is no ground for setting aside the contract, that one of them was at the time *non compos mentis*. On appeal to the Exchequer Chamber this judgment was affirmed in May, 1849. (See also the case of *Staniland v. Willet*, Vice-Chancellor's Court, Nov. 1848.) In the case of *Donat v. Haniquet* (Guildhall Sittings, 1854), on an action to recover a sum of money, in which the defence was that the defendant was of unsound mind at the time of the contract, Crompton, J., held that unless it was shown that the plaintiff had taken advantage of defendant's unsoundness of mind, he would be entitled to recover the amount claimed.

[In the case of *Leach v. Marsh*, "American Law Reg.," vol. 2 (N. S.), p. 22, the Supreme Court of Maine decided that a judgment recovered on default, against a person admitted to have been *non compos mentis* at the time of the proceedings in the case, will be reversed on a writ of error brought by his administrators after his decease. The following is the note of one of the editors (Hon. I. F. Redfield) of the

‘Register:’ “It seems well settled that contracts by lunatics and persons of unsound mind, as a general rule, are not binding.” *Lincoln v. Buckmaster*, 32 Vt. R. 652, and numerous cases there cited. But there are many exceptions to this rule:—

1. Where merchants, apparently sane, have purchased goods in the ordinary course of their business, and have disposed of them, in whole or in part, so that the goods cannot be restored to the seller, there is no question of the general liability upon such contracts, notwithstanding it should appear that the purchaser was in fact insane at the time of the purchase. *Braes v. Lee*, 10 Barr 56; *Molton v. Camaroux*, 2 Exch. R. 502; S. C. 4 Id. 17. And the same rule extends to all cases where the seller has parted with his property in good faith, and it is not in the power of the lunatic to restore it. Even courts of equity refuse to interpose to set aside the contracts of lunatics, unless the parties can be restored to their former condition, or the sane party has taken some unconscionable advantage in the bargain. *Neil v. Morley*, 9 Vesey 478. The parties are left to their legal rights. *Sageron v. Leaky*, 2 Atk. R. 412. The same rule extends to contracts made with infants. *Farr v. Sumner*, 12 Vt. R. 28; *Taft v. Pike*, 14 Id. 405; *Weed v. Beebe*, 21 Id. 495. But the recovery in both cases should be upon the *quantum meruit*, rather than upon the contract.

2. Contracts for necessities for the lunatic or his family are binding to the same extent, and much upon the same principles as similar contracts by infants. *Thomson v. Leach*, 3 Mod. R. 310; *Seaver v. Phelps*, 11 Pick. R. 304, 306. Some of the American cases go the length of holding that no recovery can be had against a lunatic, upon a contract express or implied, unless for necessities. *Seaver v. Phelps*, *supra*; *Fitzgerald v. Reed*, 9 Sm. and Marshall; *Pearl v. McDowell*, 3 J. J. Marsh. 658; 2 Greenl. Ev. § 369; *Lincoln v. Buckmaster*, *supra*.

The rule in regard to instituting legal proceedings against a lunatic is much the same as that which obtains in the case of infants; and there would seem to be more reason for a strict enforcement of it in the former case than in the latter, since infants, long before they get out of their nonage, are entirely competent to select counsel, and conduct the defence of a suit.

This subject is very elaborately discussed by *Woodbury, J.*, in *Lang v. Whidden*, 2 N. H. R. 435, where the authorities, prior to that date (1822) will be found very extensively quoted, and the subject very learnedly discussed, and satisfactorily disposed of by the court. It is here said the guardian must be notified, in all cases, or the judgment will be erroneous.

The same rule has been adopted in many of the American States. *Albridge v. Montgomery*, 9 Ind. R. 302; *Snowden v. Danbury*, 11 Penna. St. R. 522; 2 Barb. Ch. R. 387; *Wright's Ap.*, 8 Barr 57; 6 B. Mon. R. 239. But if one who is a lunatic be arrested or imprisoned in a civil suit, he is not entitled to his release on that account. A guardian *ad litem* may be appointed, and the suit proceed. *Bush v. Pettibone*, 4 Comst. R. 300; *Aldrich v. Williams*, 12 Vt. R. 413.

There seems to be no good ground to question the decision in the principal case. The same rule has long been established in regard to

judgments rendered against infants, without the appointment of guardians *ad litem*. 2 Saund. R. 212, N. H.; *Castlemain v. Moody*, 4 B & Ad. 90. See also *Masm v. Dennison*, 15 Wendell 64; *Wead v. Marsh*, 14 Vt. R. 77; *Crockett v. Drew*, 5 Gray 399.

In the case of *Van Brunt v. Taylor*, 3 Philadelphia R. 123, it was held by the District Court, that where an insane partner contracted loans, the firm was liable, whether the money was misappropriated by him or not.

By act of 13th June, 1836, § 44, no person, found by inquisition to be a lunatic, can in Pennsylvania, be arrested or imprisoned on mesne or final process in any civil action, so long as he shall remain of unsound mind.—P.]

Testamentary capacity. Wills made by the insane.—Questions involving the testamentary capacity of persons are of very frequent occurrence, and medical evidence is commonly required for their solution. When property is bequeathed by a testator out of the usual order of succession, it may be alleged by the relatives that he was wholly incompetent to understand the nature of the deed—either from actual insanity, the imbecility of age, or that natural failing of the mind which is so often observed to occur from disease, or on the approach of death. A *disposing* mind is what the law requires to render a will valid, and this does not rest so much upon the question of sanity or insanity, as upon the proof of competency or incompetency in the testator. The best test of capacity for this act is that a man, at the time of signing the will, should know the nature and amount of his property and the just claims of those who are nearly related to him. It has been truly said that the evidence of the medical attendant on the state of the testator's mind at the time of the execution of the will, is worth more than the opinions of experts or of witnesses who may have seen the testator at other times and under other circumstances. ("Med. Times and Gaz.," 1871, 2, 203.) A medical man is frequently of necessity a witness to a will. He should always remember that when he signs his name to it as a witness, he is practically testifying to the competency of the testator to make it.

Bodily disease or incapacity does not affect the validity of a will, unless the mind is directly or indirectly disturbed by it. A man's mind, under these circumstances, may not be so strong as in robust health, but still it may retain a disposing power. In *Harwood v. Baker*, decided by the Privy Council in 1841, a will was pronounced to be invalid owing to the general state of bodily disease in which the testator was, at the time of making it. It appears that he was laboring under erysipelas and fever, and these diseases had produced a degree of drowsiness and stupor which rendered him incompetent to the act. In the case of *Day* (June, 1838), epilepsy was alleged to have affected the mind; and in the case of *Blewitt* (March, 1833), paralysis was adduced as a ground of incompetency. In all cases of this kind, the law looks exclusively to the actual effect of the bodily disease upon the mind at the time the will is made; and this is a question commonly to be determined by a jury from the testimony of the usual medical attendant of the deceased, as well as from the evidence of medical experts.

Test of capacity.—A person is considered to be of a sane and disposing mind who knows the nature of the act which he is performing, and is fully aware of its consequences. From some decisions that have been made, it would appear that a state of mind for which a person might be placed under interdiction, or deprived of the management of his affairs, would not render him incompetent to the making of a will. The validity of the will of a lunatic was once allowed, although made while he was actually confined in an asylum, because the act was rational, and it was such as the lunatic had announced his intention of making, some years prior to the attack of insanity. (*Coghlan's case*; see *Re Garden*, "Law Times," July 6, 1844, p. 258; also, the case of *Cartwright*, Mayo on "Medical Testimony," p. 44.) In *Nichols and Freeman v. Binns* (Probate Court, Aug. 1858), the question was whether the will of a Mr. Parkinson, made in a lunatic asylum near Norwich, was executed during a lucid interval. The jury found a verdict in favor of the will. In *Parker v. Lord*, June, 1876, the testator Lord, a surgeon, was afflicted with insanity in January, 1875. It was proved that he had lucid intervals. He executed his will in the following February. The court pronounced for the will, in which there was a reasonable disposition of his property, on the ground that it had been executed during a lucid interval.

The insanity of a person when not already found insane under a commission, must not in these cases rest upon presumption or probability, but be established by positive proof. The act of suicide is often hastily assumed to be evidence of insanity; but it would not be allowed as a proof of this state, even when a testator had destroyed himself shortly after the execution of his will. A case has been decided where the testator committed suicide three days after having given instructions for his will; but the act was not admitted as a proof or even as a presumption of insanity at the time, and the will was pronounced to be valid. In another case, *Edwards v. Edwards* (Prerog. Court, Feb. 1854), it was proved that the testator had committed suicide three days after the execution of his will, and there was some evidence of eccentric habits almost amounting to insanity; but the will was found valid. In *White v. Halford* (Probate Court, Feb. 1874), a will was contested on the ground that the testator had thrown himself out of his bedroom window, and had inflicted some severe injuries on himself a night or two before the will was made. He repeated these attempts on himself, and eventually died in a lunatic asylum. The jury found in favor of the will. There was no proof that the testator was laboring under any delusion when it was made. Suicide alone is not deemed to be such a proof of the existence of insanity as to render a will invalid.

Delusion in the deed.—The validity of deeds executed by persons affected with monomania is often a subject of dispute. The practice of the law indicates that the mere existence of a delusion in the mind of a person does not necessarily vitiate a deed, unless the delusion form the groundwork of it, or unless the most decisive evidence be given that, at the time of executing the deed, the testator's mind was influenced by it. Strong evidence is often derivable from the act itself, especially when a testator has drawn up the will of his own accord. In the case of *Barton*

(July, 1840) the Ecclesiastical Court was chiefly guided in its decision by the nature of the instrument. The testator, it appeared, labored under the extraordinary delusion that he could dispose of his own property to himself, and make himself his own legatee and executor! This he had accordingly done. The will was pronounced to be invalid. But a will may be manifestly unjust to the surviving relatives of a testator, and it may display some of the extraordinary opinions of the individual, yet it will not necessarily be void, unless the testamentary dispositions clearly indicate that they have been made under the influence of a *delusion*. Some injustice may possibly be done by the rigorous adoption of this principle; since delusion may certainly enter into a man's act, whether civil or criminal, and it may not be always in our power to discover it; but, after all, this is perhaps the most equitable mode of construing the last wishes of the dead. The proof of the existence of delusion may be very close upon the date of the will, as in *Sewell v. Wells* (Probate Court, June, 1877), and yet the will may be held to be valid. The testator made his will on the tenth of March, 1875. It was admitted on both sides that he was insane in May, 1875, and there was evidence that he was laboring under delusions regarding himself and his property on the 15th of March, *i. e.*, four days after the date of the will. The jury found that there was no delusion when he made the will.

Delusions may exist without being in all cases manifest or discoverable. Persons who have committed suicide, or who have destroyed their own property, or done any other act from which unsoundness of mind might be inferred, might be enabled to conceal the delusions under which they labored down to the last moment of their lives.

According to Sir John Nichol, it is not necessary in civil suits to connect the morbid imagination with the act itself; if the mind is proved to be unsound the act is void. In *Roberts v. Kerslake* (Warwick Aut. Assizes, 1854), Lord Wensleydale held that to vitiate a will, if it be a case of delirium, the act must be traced to delirious delusion, but if it be a case of lunacy it need not be traced to a delusion. In *Sharpe v. Macauley* (Winchester Aut. Ass., 1856), Martin, B., advised the jury, in coming to a conclusion on the question, whether the testator had a "sound and disposing mind," to look not to the opinions of others, but to the man's own acts as well as his correspondence. A disposing mind implied that a man understood the nature of his property, the use and benefits arising from it, and had sense and discretion to select persons to enjoy it after his death. A man may have labored under delusions and have been confined as a lunatic, yet at the date of his will he may have been sane and have had a disposing power. The main question therefore is—Was the testator of sane mind when the will was executed? This may be deduced from direct evidence of his condition as well as from the provisions of the will itself.

Eccentricity in wills.—The evidence in these cases sometimes amounts to proof of eccentricity only on the part of the testator, or in the deed itself; but a clear distinction must be here drawn. The will of an eccentric man is such as might always have been expected from him: the will of one laboring under insanity (delusion) is different from that which he would have made in an unaffected state—the instrument is wholly

converted into fiddle-strings—that others should be sublimed into smelling-salts, and that the remainder of his body should be vitrified into lenses for optical purposes!” He further added, in a letter attached to his will—“The world may think this to be done in a spirit of singularity or whim; but I have a mortal aversion to funeral pomp, and I wish my body to be converted into purposes useful to mankind!” Sir H. Jenner, in giving judgment, held that insanity was not proved: the facts merely amounted to *eccentricity*, and on this ground he pronounced for the validity of the will. It was shown that the deceased had conducted his affairs with great shrewdness and ability; that he not only did not labor under imbecility, but that he had been always treated during life as a person of indisputable capacity by those with whom he had to deal. The best rule to guide the court, the judge remarked, was the conduct of persons towards the deceased; and the acts of his relatives evinced no distrust of his sanity or capacity while he was living. The deceased had always been noted for his eccentric habits, and he had actually consulted a physician upon the possibility of his body being devoted to chemical experiments after death. In the case of *Mudway v. Craft* (Prerog. Court, Aug. 1843), a will contested on the ground of insanity but defended on the plea of eccentricity, Sir H. J. Fust said: “It is the prolonged departure, without an adequate external cause, from the state of feeling and modes of thinking usual to the individual when in health, that is the true feature of disorder of the mind.”

Within a recent period two cases have come before the Probate Court, in which it has been necessary to draw the line between eccentricity and insanity in reference to wills. Although the facts proved in reference to insanity in the two cases were somewhat similar, the decision was in favor of the will in one case and adverse to it in the other. In both there was a departure from the rule which has hitherto influenced justly the verdicts of juries, *i. e.*, in the ignoring of the fact that the testator in each case had managed his affairs during life without any imputation on his sanity or competency, or any interference in his affairs on the part of relatives. (*Davis v. Gregory*, and *Boughton v. Knight*, Probate Court, 1873.)

Wills in senile dementia.—Wills made in incipient dementia arising from extreme age (senile imbecility) are sometimes disputed, either on the ground of mental deficiency, or of the testator, owing to weakness of mind, having been subjected to control and influence on the part of interested persons. If a medical man be present when a will is executed, he may easily satisfy himself of the state of mind of a testator, by requiring him to repeat from memory the mode in which he has disposed of the bulk of his property. A medical man has sometimes placed himself in a serious position by becoming a witness to a will without first assuring himself of the actual mental condition of the person making it (case of the *Duchess of Manchester*, 1854). It would always be a good ground of justification, if, at the request of the witness, the testator is made to repeat substantially the leading provisions of his will from memory. If a dying or sick person cannot do this without prompting or suggestion, there is reason to believe that he has not a sane and disposing mind. It has been observed on some occasions, when the mind has been

weakened by disease or infirmity from age, that it has suddenly cleared up before death, and the person has unexpectedly shown a disposing capacity. ("Ann. d'Hyg.," 1831, p. 360.) In *Durnell v. Corfield* (Prerog. Court, July, 1844), a case in which an old man of weakened capacity had made a will in favor of his medical attendant, Dr. Lushington held that to render it valid, there must be the clearest proof not only of the *factum* of the instrument, but of the testator's knowledge of its contents. ("Law Times," July 27, 1844.) [In *Greenfield's Estate*, 2 Harris (Penna.) 489, where the decedent during her lifetime had at the age of eighty-six or eighty-seven, executed a deed to persons who were to hold in trust for her for life, and after her death to administer the property in the manner therein set forth, it was held, that a provision in the deed in favor of the counsel who drew or advised it, for his services to be performed as trustee, with the further provisions that such trustee might resign, without forfeiting his compensation, is void, at least unless it be proved that the grantor knew of the particular provisions, and without influence from those interested, assented to them. If a *doubt exists* in this respect the provision for compensation is invalid; and the provision in favor of the other trustees who acted in the arrangement of the matter, through the counsel, or in connection with him, is also invalid. The trustees may, however, be decreed compensation by the proper tribunal.—P.] In *West v. Sylvester* (Nov. 1864), Sir J. Wilde, in pronouncing a judgment against a will propounded as that of the deceased, an aged lady, said: "At the time she executed the will of October, 1863, although for many purposes she might be said to be in her right senses, she was nevertheless suffering from that failure and decrepitude of memory which prevented her from having present to her mind the proper objects of her bounty, and selecting those whom she wished to partake of it."

Wills in extremis.—Wills made by persons whose capacity during life has never been doubted, while lying at the point of death, or, as it is termed, *in extremis*, are justly regarded with suspicion, and may be set aside according to the medical circumstances proved. Many diseases, especially those which affect the brain or nervous system, directly or indirectly, are likely to produce a dulness or confusion of intellect, under which a proper disposing power is lost. Delirium sometimes precedes death, in which case a will executed by a dying person thus affected would be at once pronounced invalid.

[By a statute law of Pennsylvania (Act of 26 April, 1855), bequests to public institutions are invalid, without regard to the testamentary capacity of the party making the bequests, if made within thirty days of death of testator.—H.]

In examining the capacity of a person under these circumstances, we should avoid putting leading questions—namely, those which suggest the answers "yes" or "no." Thus, a dying man may hear a document read over, and affirm, in answer to such a question, that it is in accordance with his wishes, but without understanding its purport. This is not satisfactory evidence of his having a disposing mind: we should see that he is able to dictate the provisions of the document, and to repeat them substantially from memory when required. If he can do this accurately, there can be no doubt of his possessing complete testamentary capacity.

But it may be objected that many dying men cannot be supposed capable of such an exertion of memory: the answer is then very simple; it is better that the person should die without a will, and his property be distributed according to the law of intestacy, than that, through any failure of his mind, he should unknowingly cut off the rights of those who have the strongest claims upon him.

Habitual Intemperance.—A man may be of drunken habits, and yet not incapacitated for making a will. In *Smith v. Austen* (Probate Court, Nov. 1875), Sir J. Hannen pronounced in favor of the will of a man who was proved to have been of exceedingly drunken habits. The question was, whether his mental faculties had been thereby enfeebled so as to render him incapable of exercising his judgment. There was no proof of this, and during life he had not been treated by anybody as incapable of managing his affairs.

Effect of narcotics.—The habitual use of opium or other narcotics, may give rise to a question respecting testamentary capacity. I have been consulted in a case of this kind, in which the testator had been in the habit of taking morphia, until, according to my informant, the dose had reached fifteen grains a day. He made a will fairly disposing of his property among his children. Nine days afterwards he made another will, entirely revoking the previous one, leaving his property to a younger son, who was supposed to have exerted an undue influence.

The long use of narcotics, in large doses, may weaken the powers of the mind, and render a man more easily amenable to improper influence; but the question will be in this case, as with drunkards, whether the habit has permanently enfeebled the mind so as to prevent a man from exercising a reasonable disposition of his property. The proof of this will rest with those who would benefit by the allegation.

Restriction of medical opinions.—In an important case (*Bainbrigge v. Bainbrigge*, Oxford Summer Ass. 1850), tried before Lord Campbell, in which the testamentary capacity of a man was disputed, it was held that a medical witness, although conversant with cases of insanity, cannot be asked his opinion as to the insanity of a testator founded upon evidence given at the trial in his hearing. (4 Cox, "Criminal Cases," 54; see, also, on this subject "Med. Gaz.," vol. 46, p. 240.) In the case of the *Duchess of Manchester*, however, the opinions of Dr. Sutherland, Mayo, and Conolly on the competency of the testatrix to make a will were received by the court although based only upon evidence given at the trial.

[In general, every man is presumed to be sane until the contrary is proved; and hence it has been held, that the burden of proving unsoundness or imbecility of mind in a testator, is upon the party impeaching the validity of a will for that cause. Especially, it is said, is this the case with reference to wills attested by subscribing witnesses, because it is the duty of the latter "to be satisfied of the testator's sanity before they subscribe the instrument" (*Werstler v. Custer*, 10 Wright, Penna.) 502); and, under the maxim "*omnia præsumuntur rite et solemniter acta donec probetur in contrarium*," it is to be presumed that they have not neglected this duty. Such is the rule in Pennsylvania, and of many of the other States in the Union; *Werstler v. Custer*,

supra; *Grabill v. Barr*, 5 Barr 441; *Barber v. McFerren*, 2 Casey 214; *Rees v. Stille*, 2 Wright 138; *Jackson v. Vandusen*, 5 Johns, 144; *Dean v. Dean*, 1 Williams (Vt.) 746; *Trumbull v. Gibbons*, 2 New Jersey 117; *Hawkins v. Grimes*, 13 B. Monroe (Ky.) 257; *Perkins v. Perkins*, 39 New Hamp. 163; *Stubbs v. Houston*, 33 Ala. 555; *McDaniel v. Crosby*, 19 Ark. 533; *Chandler v. Feeris*, 1 Harrington (Del.) 454.

But, on the other hand, in *Harris v. Ingledew*, 3 P. Wms. 93, Sir Joseph Jekyll, M. R., said, "It must be observed that the proof of a will is attended with more solemnity than that of a deed; the former being supposed to be made when the testator is *in extremis*; and, therefore in equity, it is *necessary to prove the sanity*, which is all presumed in the case of the latter." See also *Barry v. Butlin*, 1 Curtis 637; *Sutton v. Saddler*, Com. B. 19 Law. Rep. N. S. 703; and this is said to be more particularly the rule where the statute relating to wills contains the provision (which indeed it generally does) that the testator must be of "sound mind." *Cilley v. Cilley*, 34 Maine 162; *Comstock v. Hadlyne*, 8 Conn. 261; *Crowningshield v. Crowningshield*, 2 Gray 524; *Brooks v. Barrett*, 7 Pick. 98, 99.

The subject of testamentary capacity is very fully considered in Jarman on Wills, Perkin's Ed. vol. 1, p. 51, *et seq.*; and in Williams on Executors, vol. 1, p. 11, *et seq.* To the authorities there cited, may be added the recent cases of *Vanpelt v. Vanpelt*, 30 Barb. (N. Y.) 134. *Dunham's Ap.*, 27 Conn. 192; *Stubbs v. Houston*, 33 Ala. 555; *Rees v. Stille*, 2 Wright 138; *Aiman v. Stout*, 6 ib. 114; *Eckert v. Henry*, 7 ib. 46; *Daniel v. Daniel*, 3 ib. 191; *Werstler v. Custer*, 10 ib. 502. In the case of *Vanpelt v. Vanpelt*, it was held that though a testator's capacity was slender, yet, if the evidence is sufficient to show that he fully understood, and intended to make the disposition which he has made, the will must stand, however unnatural and unjust may be its provisions. And in *Stubbs v. Houston*, it was held, that though a condition somewhat short of a total deprivation of reason will destroy testamentary capacity, yet that a person not competent to transact the ordinary business of life, may make a will. The existence of insane delusions was held in *Dunham's Ap.* not to incapacitate, if the testator has mind enough to know and appreciate his relations to the natural objects of his bounty, and the character and effect of the dispositions of his will. In Pennsylvania, mere weakness of intellect, however great, will not take away testamentary capacity, providing the testator at the time of his executing his will, has a full and intelligent consciousness of the nature and effect of the act he is engaged in, a knowledge of the property he possesses, an understanding of the disposition he wishes to make, and of the persons and objects he desires to participate in his bounty. It is not necessary, however, that he should collect all these in one review. *Daniels v. Daniels*, *Rees v. Stille*, etc.

It is the duty of every one called upon to attest a will to first satisfy himself of the competency of the testator. If he has doubts, he should refuse to sign his name. Courts have spoken in the severest terms of persons who, having become witnesses to wills, have afterwards come forward to testify as to the insanity of the testator. The act of attesta-

tion solemnly testifies the testator's competency; so that the person who, believing that this does not exist, nevertheless signs his name as a witness, becomes an instrument in what he himself considers a fraud. Should such witness afterwards attempt to impeach his own act, and to prove that the testator did not know what he was doing when he made what purported to be his will, though the evidence would not be positively inadmissible, very little credit is to be attached to it. *Rees v. Stille*, 2 Wright 140. The older cases go so far as to say that the testimony should not be received at all, upon the maxim of the civil law, *nemo allegans suam turpitudinem est audiendus*; and in *Lowe v. Jolliffe* (1 W. Blackstone's Rep., 365), where, notwithstanding the testimony of the subscribing witnesses against it, the will was supported, Lord MANSFIELD sent for those witnesses in order to have them committed for perjury; but, as the reporter states, they very prudently "had withdrawn themselves." It is now settled, however, that the question is one not for the court but the jury, who are to receive the evidence, but with the most scrupulous jealousy (*Booth v. Blundell*, 19 Ves. 504); bearing in mind, as declared by WOODWARD J., in *Werstler v. Custer*, 10 Wright (Penna.) 502), that "no honest man will subscribe as a witness to a will or other instrument, executed by an insane man, an imbecile, or an idiot." —P.]

CHAPTER LXVI.

THE PLEA OR DEFENCE OF INSANITY.—CIRCUMSTANCES UNDER WHICH IT IS ADMISSIBLE.—HOMICIDAL INSANITY.—MORAL INSANITY.—SYMPTOMS—LEGAL TESTS.—MEDICAL TESTS.—DELUSION.—TESTS OF IRRESPONSIBILITY.—MEDICAL EVIDENCE.

The plea or defence of insanity.—Responsibility here signifies nothing more than liability to punishment for crime, and a criminal act implies the existence of intention, will, and malice. (Stephen.) When insanity has reached a certain stage or degree, an act may be perpetrated without malice; and in this sense the person is considered to be irresponsible in law. This is a question of *fact*, to be determined by a jury from the whole evidence set before them; and the proof rests with those who make the allegation that the act in question, whether murder or arson, was not done wilfully and maliciously. "The sanity of a man's conduct," observes Sir James Stephen, "involves the presence of intention and will on all ordinary occasions; and if the act is one of those which the law forbids, it is presumed to be malicious and wicked." ("Criminal Law of England," p. 89.) This subject is of considerable importance in a medico-legal view; for should a plea of insanity be improperly admitted in any criminal case, then punishment is made to fall unequally on offenders; and if, on the other hand, it be improperly rejected, punish-

ment is administered with undue severity, and loses its deterrent influence. The rule of law is, that no man is responsible like a sane person for any act committed by him while in a state of insanity. This plea may be raised for the smallest offence up to the highest crime—murder; but it is rarely made a defence in smaller offences, because the close confinement to which an accused person, if found insane, would necessarily be subjected, would often be a heavier punishment than that which the law actually prescribes for the offence which he may have committed. In a case of felonious assault, it was urged by counsel in defence, that the prisoner was insane; but the evidence on this point was not by any means conclusive—when it was intimated by the court that, if this plea were admitted, the party would probably undergo a much longer imprisonment than if on conviction he received the legal punishment for the offence! (*The Queen v. Reynolds*, Bodmin Aut. Ass. 1843.) The judge is reported to have said that there was no proof of insanity. If the prisoner was pronounced insane, he might be imprisoned for life, and, therefore, he did not think that *that* finding would benefit him! A verdict of guilty was returned, and the man was sentenced to eighteen months' imprisonment. This case shows that a defence of this kind may be sometimes indiscreetly put forward. Such a mode of dealing with the plea of insanity, *i. e.*, of making it a question of expediency dependent on the amount of punishment for the offence, must be pronounced as unsafe and indefensible.

The discharge of persons who have perpetrated a criminal act or heinous crime, but have been acquitted on the ground of insanity, and confined during her majesty's pleasure, is a very serious matter, and one in which the safety of the public is deeply concerned. Some medical men appear to think that the interest of the prisoner alone is to be considered; but this would lead to the discharge of many dangerous lunatics. (*Dodwell's case*, *ante*, p. 808.)

Murder, incendiarism, and theft are the crimes for which the plea of insanity is commonly raised; and it has been generally confined in this country to those cases in which persons have been charged with murder or attempts at murder. Murder may be perpetrated by one who is obviously laboring under delirium or violent mania, or by an idiot or imbecile. Apart from the circumstances connected with the criminal act, there may be clear evidence of such a disordered state of mind in the person, as at once to exonerate him from that amount of responsibility which is exacted from one who is sane. The appearance of the accused, or the testimony of a medical man, renders it unnecessary to go into the evidence, and a verdict is returned accordingly. The cases of difficulty are those in which insanity presents itself in a doubtful aspect, as in mania, complicated with epilepsy, or in some forms of imbecility. The mental disorder may be of so slight a nature as not legally to justify an acquittal for murder. In order to exculpate a person it must be proved that insanity in a certain degree existed at the time of the perpetration of the act. Whether the prisoner is or is not insane when placed on his trial, is immaterial in reference to the question of responsibility. In the case of *Murray* (tried before the High Court of Justiciary, Edinburgh, Nov. 1858), it was proved that the accused recovered his sanity

eight hours after he had killed the deceased ; but he was acquitted on the ground of insanity at the time of committing the act.

The proved existence of mental disease does not necessarily exempt a person from criminal responsibility. Many a man whose mind is in an unsound state knows perfectly well whether he is doing wrong ; and so long as he knows *that*, he is considered to be subject to the criminal law. Even the existence of a morbid delusion cannot always be allowed to screen a criminal from the consequences of his own acts, while on the other hand, there are instances in which a plea of insanity may be properly allowed, although no delusion can be proved. Each case must be taken with all its surrounding circumstances.

The great difference of opinion which exists between physicians and jurists in reference to this plea, appears to me to consist in this: Most jurists contend that no degree of insanity should exempt from punishment for crime, unless it has reached that point *that the person is utterly unconscious of the difference between right and wrong at the time of committing the alleged crime*. Physicians, on the other hand, affirm that this is not a proper test of the existence of that degree of insanity which should exempt a man from punishment for his acts ; that those who are laboring under confirmed insanity, and who have been properly confined in asylums for years, are fully conscious of the difference between right and wrong, and are quite able to appreciate the illegality as well as the consequences of their acts. Again, those who have patiently watched the insane for years, agree that the legal test of utter unconsciousness of right and wrong in the performance of acts, would in reality apply only to persons who were suffering from delirium, from a furious paroxysm of mania, or from confirmed idiocy ; and that if the rule suggested—that a person, in order to be acquitted on the ground of insanity, should be first proved to be as *unconscious* of his act as a *baby* (Warren)—were strictly carried out, there is scarcely a lunatic inmate of an asylum, who destroyed a keeper or attendant, who might not be executed for murder. Such a rule amounts to a *reductio ad absurdum*: it would abolish all distinction between the sane and the insane, between the responsible and the irresponsible ; and it would consign to the same punishment the confirmed lunatic and the sane criminal. This species of *baby-unconsciousness of action* exists in idiots as well as in furious maniacs, but not in the majority of lunatics ; and it may be safely asserted that, if this criterion be the true one, acquittals on the ground of insanity have involved a series of gross mistakes for the last fifty years. It may be said that the consciousness of the insane is an insane consciousness, while the law implies the consciousness of a sound mind ; but this involves a *petitio principii*. There have been numerous cases of acquittal in which, until the act of homicide had been committed, there was no imputation either against the sanity or the sane consciousness of the accused. Having pointed out these inconsistencies, it is only proper to acknowledge that in theory the English law would punish a lunatic just as it would punish a sane man, provided the lunatic “ had that degree of intellect which enabled him to know and distinguish between right and wrong, or between what was lawful and unlawful ; if he knew what would be the effect of his crime, and consciously committed it ; and further, if

with that consciousness he wilfully and intentionally committed it." In practice, however, it is placed beyond doubt that some who ought to be convicted under these rules, are acquitted on the legal assumption that they were at the time unconscious (or only insanely conscious) of the wrongfulness of their acts. Dr. Wood states, that of thirty-three men confined as lunatics in Bethlehem, who had actually committed murder, *three* were reported sane; he feels quite satisfied that two of these were *not insane* at the time they committed the murders; and of fifteen men who had attempted murder, five were reported sane, and two of them ought, in his judgment, never to have been acquitted on the ground of insanity. ("Plea of Insanity," p. 50.) According to the late Sir W. Hood, in the six years from 1852 to 1858, 120 persons who were tried for murder, for attempts at murder, or acts of personal violence, were acquitted on the ground of insanity. Of that number, 79 were received into Bethlehem Hospital, and in several instances they exhibited no symptoms of insanity while they were resident in the asylum. These facts, then, are sufficient to show that the rule of law generally adopted, certainly does not err on the side of severity. The only complaint that can be made is, that it operates with great uncertainty. Of late years some learned judges have admitted that there might be a consciousness that the act was wrong and illegal, and yet the person would be exempted from criminal responsibility, provided it was proved by other circumstances that he labored at the time under a disease of the mind sufficient to prevent him from exercising a proper control over his actions.

When the defence of insanity is set up on a charge of murder,—in order to warrant the jury in acquitting a prisoner, it must be proved affirmatively that he was *insane in a certain legal sense at the time of perpetrating the act*: if this be left in doubt, and if the crime charged in the indictment be proved, it is their duty to convict him. (*Reg. v. Stokes*, 3 Car. and Kir. p. 185.) It is necessary to impress upon the mind of the medical witness, that it is not *medical* but *legal* insanity which is required to be proved on these occasions to the satisfaction of a jury. As no two medical men agree about what is madness in a medical sense, and as some "mad doctors" have even held that all great criminals are necessarily insane, it is obvious that the power to absolve from responsibility could not be placed in the hands of the profession with a due regard to the protection of society, or a safe administration of the law. The facts stated by Drs. Hood and Wood, in reference to the admission of alleged criminal lunatics into Bethlehem (*supra*), show that either by legal or medical ingenuity, or both combined, sane criminals are liable to be incarcerated as irresponsible lunatics!

Homicidal insanity.—Homicidal mania or monomania is commonly defined to be a state of partial insanity, accompanied by an *impulse* to the perpetration of murder: hence it is sometimes called impulsive or paroxysmal mania. There may or may not be evidence of *intellectual* aberration, but the main feature of the disorder is the existence of a destructive impulse which, like a delusion, cannot be controlled by the patient. This impulse, thus dominating over all other feelings, leads a person to destroy those to whom he is most fondly attached, or any one who may be involved in his delusion. Sometimes the impulse is long

felt, but concealed and restrained; there may be merely signs of depression and melancholy, sleeplessness, low spirits, and loss of appetite, as well as eccentric or wayward and restless habits, but nothing to lead to a suspicion of the fearful contention which may be going on within the mind. As in suicidal mania, many of those who are in habits of daily intercourse with the patients, have been first astounded by the act of murder, and then only led to conjecture that certain peculiarities of language or conduct, scarcely noticed at the time, must have been symptoms of insanity. Occasionally the act of murder is perpetrated with great deliberation, and apparently with all the marks of sanity. These cases are rendered difficult by the fact that there may be no distinct proof of the existence, past or present, of any disorder of the *mind*, so that the chief evidence of mental disorder is in the *act* itself: of the existence of insanity, in the common or legal acceptation of the term, before and after the perpetration of the crime, there may be either no evidence whatever, or it may be so slight as not to amount to legal proof. Such cases are regarded and described by some medico-legal writers as instances of *insanity of the moral feelings* only, and this condition has been called "*Moral insanity*," *mania sine delirio* (p. 779, *ante*). Its existence, as a state independent of a simultaneous disturbance of the reason or intellect, is denied by the great majority of lawyers, as well as by some eminent medical authorities. Whether such a condition exists or not is a simple question of fact, to be established, if possible, by clear and conclusive evidence. Its existence in the case of a person charged with murder appears to have rested hitherto on a mere medical dictum. Intelligible reasons have not been assigned by those witnesses who have sought to satisfy a court of law that this has as distinct an existence as intellectual insanity; in general, it is only alleged and not proved to exist in a given case. If its existence were satisfactorily established, it would, as Sir J. Stephen observes, do away with one of the essential ingredients of crime—malice, and thus justify a jury in acquitting a person charged with murder. The accused on these occasions is assumed to have been an involuntary agent. As Sir J. Stephen suggests, it might be a good defence to admit that a man loaded a pistol and pointed it at the head of another, but that it was fired by a sudden involuntary action of the necessary muscles, and not by the prisoner's will. The only difficulty is to get a jury to believe it! The evidence given in support of the assertion that a man is morally insane, generally speaking, is at least as consistent with the theory that he is a great fool and a great rogue, as with the theory that he is the subject of a special disease, the existence of which is doubtful. ("Crim. Law," p. 95.) There is no doubt that the unrestricted admission of such a theory would go far to do away with all punishment for crime, for it would render it utterly impossible to draw a line between (moral) insanity and moral depravity. What is crime but the perversion of moral feelings? Moral insanity in a person of *sound mind* is a contradiction in terms; whenever the mind is sound a man's conscience and sense of right and wrong will always be sufficient to enable him to restrain and control evil desires and impulses. In dealing with this subject Dr. Orange, the superintendent of Broadmoor Asylum, thus expresses himself: "Moral depravity, it has been said,

cares not for law ; moral insanity cares, but cannot obey ; but even if this were admitted as a correct distinction, it would still be necessary to prove that such inability to obey arises from defect of judgment, or of will, or of self-control, as a result of mental disease." ("Relation of Insanity to the Criminal Law of England," 1877, p. 10.)

Examination of maniacs.—Homicidal mania may coexist with a quiet exterior, disarming all suspicion. Medical men who are required to examine patients cannot be too distrustful in dealing with them. With astounding cunning they will prepare and conceal weapons of destruction, which may be used in an instant and without warning. The case of *Reg. v. McKane* (Salisbury Summer Ass., 1873) furnishes a proof of the difficulty of guarding against sudden acts of violence. The prisoner was charged with the murder of Mr. Lutwidge, a Commissioner in Lunacy. The prisoner had been confined in an asylum for many years. He was anxious to be removed from the Fisherton Asylum, where he then was, and to go to Broadmoor. He had threatened to do something which would send him to some other place, but he had not been treated as a dangerous lunatic. As the commissioner was going round the asylum, with others, for the purpose of inspection, the prisoner suddenly made a rush at him, and struck him violently on the temples with a large nail wrapped in a cloth. It penetrated to the brain of deceased, and he died in a week afterwards. Medical evidence was given to show that the prisoner was suffering from chronic mania ; that he was subject to delusions, and that he was not responsible for his actions on this occasion.

It has been justly observed that the border line between sanity and insanity is so thin, that even experienced persons who have been all their lives associated with the insane may be deceived, when in reality the mind is unsound and the patient unsafe. A Commissioner of Lunacy was so deeply impressed with the conviction that an inmate of an asylum who, as usual, asserted that he was perfectly sane, and was improperly detained, that, in defiance of the physician's warning, he trusted himself alone in the lunatic's company, for the purpose, as he said, of a private conversation. In less than five minutes after they were alone, and, as the lunatic believed, unobserved, the commissioner was throttled by his companion, and but for the timely intervention of the physician, who had been a secret spectator of the scene, he would have been strangled. Some years since, Mr. Vance, an eminent London physician, called to see a lunatic patient. When he had reached the top of the stairs, the patient suddenly rushed at him and threw him down the flight, killing him on the spot. (See p. 807.)

Symptoms.—Homicidal mania in its more common form, may make its appearance at all ages, even, it is said, in children : it is occasionally periodical, and the paroxysm of insanity is preceded by symptoms of general excitement. The patient experiences colicky pains, and a sense of heat in the abdomen or chest,—headache, restlessness, and loss of appetite, with lowness of spirits ; the face is flushed or pale, the pulse hard and full, and the whole body is in a state of convulsive trembling. An act of violence is committed without warning, and the patient appears as if relieved from some oppressive feeling. He may be calm, and express neither regret, remorse, nor fear ; he may coolly contemplate his

victim, confess the deed, and at once surrender himself to justice. In some rare instances he may conceal himself, hide the weapon, and, like a sane criminal, endeavor to obliterate all traces of the crime—thus showing a perfect consciousness of the illegality or wrongfulness of the act, and a desire to evade discovery. These are, however, the main features of crime, and unless there is independent evidence of *mental* disorder, or of some bodily disease affecting the brain and destroying the power of self-control, the conclusion must be that the person is sane and responsible. The great problem to be solved on these occasions is—What are the plain practical distinctions between defective reasoning power arising from disease and perverted moral sense? The latter condition alone should not exculpate a person or absolve him from punishment,—or persons undeniably sane who have committed crimes, should be equally exculpated and absolved from punishment.

The symptoms above described have been observed to be more aggravated in proportion as the homicidal impulse was strong. The propensity to kill is sometimes a fixed idea, and the patient can no more banish it from his thoughts than a person afflicted with insanity can divest himself of the delusive ideas which occupy his mind. (Esquirol, vol. 2, p. 105.) It has been supposed that Esquirol here implies a state in which there is no perversion of *intellect*. The facts which he mentions, however, clearly prove the contrary; for if a patient has not the power to banish from his thoughts this propensity to kill, he has passed beyond the bounds of reason, and is really insane. The admission of this fact proves that his mind must be unsound. Esquirol says—before the perpetration of the act there may be no sign of irrational conversation or conduct: but he asks the question—Because there is no proof of irrationality, are we to assume that these persons possess reason? Is it possible to reconcile the existence of a rational state of mind with the murder of those who are most dear to them? (Op. cit., vol. 2, p. 102.) In Esquirol's view, therefore, it may be taken that mere perversion of *feelings*, irrespective of some latent aberration of *intellect*, does not exist, and moral inasanity is a conventional term for a state in which the proofs of mental disturbance are not so clear as in the generality of cases.

An erroneous notion prevails in the public mind, that a homicidal lunatic is easily to be distinguished from a sane criminal by some *certain* and invariable symptoms or characters, which it is the duty of a medical witness to display in evidence, and of a medico-legal writer to describe. But a perusal of the evidence given at a few trials will surely satisfy those who hold this opinion, that each case must stand by itself. It is easy to classify homicidal lunatics, and say that in one instance the murderous act was committed from a motive—*i. e.*, revenge or jealousy; in a second from no motive, but from irresistible impulse; in a third from illusion or delusive motive—*i. e.*, mental delusion; in a fourth from perverted moral feeling, without any sign of intellectual aberration. This classification may comprise all the varieties of homicidal insanity, but it does not help us to ascertain, in a doubtful case, whether an act was or was not committed under any of these psychological conditions. It enables us to classify those who are *acquitted* on the ground of insanity, but it entirely fails in giving us the power to distinguish a sane from an

insane criminal, or a responsible from an irresponsible agent. According to M. Esquirol, whose views, more or less modified, are adopted by most writers on the medical jurisprudence of insanity, the facts hitherto observed indicate *three degrees* of homicidal mania:—

1. In the *first* degree, the propensity to kill is connected with absurd or irrational motives, or with *actual delusion*. The person would be at once pronounced insane. Cases of this description are not uncommon, and they rarely create any difficulty.

2. In the *second* degree, the desire to kill is connected with no *known motive*. It is difficult to imagine a rational motive for the deed; the person appears to have been led on by some impulse. There may have been *delusion* at the time, but there is no evidence of the pre-existence of this. With respect to this class of cases, Sir J. Stephen observes: “There are motives for all acts even the maddest, but it is frequently impossible to assign them specifically. It is, however, generally possible to form an opinion whether a given act was done from some unknown mad motive, or from some unknown sane motive.” (Op. cit., p. 88.)

3. In the *third* degree, the impulse to kill is *sudden*, instantaneous, unreflecting, and *uncontrollable* (*plus forte que la volonté*). The act of homicide is perpetrated without interest, without motive, and often on persons who are most fondly loved by the perpetrator. (Esquirol, “*Maladies Mentales*,” vol. 2, p. 834.) It is this form, which has been called “*impulsive insanity*,” which has given rise to so much contention on trials for murder in which insanity is set up as a defence, and therefore it will be well to consider this subject in a legal aspect. Sir J. Stephen thus comments upon it: “It is said that on particular occasions men are seized with irrational or irresistible impulses to kill, to steal, or to burn, and under the influence of such impulses they sometimes commit acts which would otherwise be most atrocious crimes. It would be absurd to deny the possibility that such impulses may occur, or the fact that they have occurred and have been acted on. Instances are given in which the impulse was felt and resisted. The only question which the existence of such impulses can raise in the administration of criminal justice, is whether the particular impulse was *irresistible* as well as *unresisted*. If it was irresistible, the person accused is entitled to be acquitted, because the act would not then be voluntary and not properly his act. If the impulse was *resistible*, the fact that it proceeded from disease would be no excuse at all. If a man’s nerves were so irritated by a baby’s crying that he instantly killed it, his act would be murder; it would not be less murder if the same irritation and corresponding desire were produced by some internal disease. The great object of the criminal law is to induce people to control their impulses; and there is no reason why, if they can, they should not control insane as well as sane impulses. The proof that an impulse was irresistible depends on the circumstances of the particular case. The commonest and strongest cases are those of women, who, without motive or concealment, kill their children after recovery from child-bed” (puerperal mania). (Op. cit., p. 95.)

In a case recently tried at the Stafford Assizes (*Reg. v. Humphreys*, Nov. 1878), in which a man was charged with the murder of his wife, the medical evidence was to the effect that the prisoner was suffering

from epileptic mania, of which an irresistible homicidal impulse was one of the features. Lord Justice Bramwell, in summing up, said everybody was presumed to be sane until proved to be the contrary. Nor was it enough that a man was mad to entitle him to an acquittal. If an insane man knew he was committing murder, that man was responsible. It was not enough to have a homicidal mania. The object of the law was to guard against mischievous propensities and homicidal impulses. A man might be suffering under a just sense of some grievous wrong or outrage which would impel him to violence, but that strong impulse, sane or insane, would not entitle him to an acquittal. He said this to the jury in order to disabuse their minds of a mischievous impression which existed, and which he believed had reached mad people themselves. He did not believe in uncontrollable impulse at all, and had never heard of such an impulse leading to action where the means of prevention were present. The jury acquitted the accused on the ground of insanity, and the learned judge expressed his full concurrence in the verdict. There was no direct proof of mental disease, but there was want of motive and an absence of any indication of ill-will against the wife.

The three forms in which a homicidal propensity may thus present itself in cases of insanity, differ from each other only in degree—the first two being strongly analogous to, but lighter modifications of the third. All the cases which came before M. Esquirol had these features in common—an irritable constitution, great excitability, singularity or eccentricity of character; and previously to the manifestation of the homicidal feeling there was a gentle, kind, and affectionate disposition. As in other forms of insanity, there was some well-marked *change of character* in the mode of life; and this may be taken as a proof that there must have been some degree of intellectual disturbance. The period at which the disorder commenced and terminated could be easily defined, and the attack could be almost always referred to some moral or physical cause. Attempts at suicide preceded or followed the attacks: all wished to die, and some desired to be put to death like criminals. In none of the cases was there any discoverable motive for the act of homicide.

M. Esquirol believes that there are well-marked distinctions between this state and that of the sane criminal. Among these he enumerates: 1. The want of accomplices in homicidal mania. 2. The sane criminal has *always* a motive—the act of murder is only a means for gratifying some other more or less criminal passion, and is almost always accompanied by some other wrongful act; the contrary exists in homicidal mania. 3. The victims of the criminal are those who oppose his desire or his wishes—the victims of the monomaniac are among those who are either indifferent to, or who are the most dear to him. 4. The sane criminal endeavors to conceal, and if taken, denies the crime; if he confesses it, it is only with some reservation, and when circumstances are too strong against him; but he commonly denies it to the last moment: it is the reverse with the monomaniac. The exceptions to which these characters are open will be considered hereafter. They have, undoubtedly, greater value in their combined than in their individual application, and when in any case they coexist, there is strong reason to believe that the person accused of murder is laboring under homicidal mania. The great diffi-

culty in these cases, however, is to distinguish *moral depravity* from *insanity*. I agree with a medico-legal writer on this subject, that "no hideousness of depravity can amount to proof of insanity, unsupported by some evidence of a judgment incapacitated, or of a will fettered by disease. In those cases in which the emotions are perverted, and where there is no clear proof of *deranged intellect*—cases which do from time to time occur—the presumption of insanity in regard to a criminal action has to be upheld by evidence of a suspension of the will from mental disease. If it can be proved that the act was not voluntary, this does away with its criminal nature." (Jamieson's Lectures on the Med. Jur. of Insanity, "Med. Gaz.," vol. 48, p. 181.) But it is impossible in many cases to produce satisfactory evidence of the suspension of the will as a result of disordered mind: this suspension can in general be *assumed* only from the act itself—a dangerous assumption, and one that might lead to the confusion of crime with insanity, and to the exculpation of all criminals.

Legal tests.—Admitting the existence of homicidal mania as thus defined by Esquirol, it may become a question how, when pleaded in defence for one charged with murder, it is to be practically distinguished from a case in which the crime has been perpetrated by a really sane person. Tests, both medical and legal, have been proposed. The *legal test* was explicitly stated in the following terms by the whole of the judges in conference, in answer to queries put by the House of Lords on the case of *M'Naughten*, who was tried and acquitted on the ground of insanity (June 19, 1843):—

"Notwithstanding a party commits a wrong act while laboring under the idea that he was redressing a supposed grievance or injury, or under the impression of obtaining some public or private benefit, he is liable to punishment. The jury ought in all cases to be told that every man should be considered of sane mind until the contrary was clearly proved in evidence; that, before a plea of insanity should be allowed, undoubted evidence ought to be adduced that the accused was of *diseased mind*, and that at the time he committed the act *he was not conscious of right or wrong*. Every person was supposed to know what the law was, and, therefore, nothing could justify a wrong act, except it was clearly proved that the party did not know right from wrong; if that was not satisfactorily proved the accused was liable to punishment. If the *delusion* under which a person labored were only *partial*, the party accused was equally liable with a person of sane mind. If the accused killed another in self-defence, he would be entitled to an acquittal; but if the crime were committed for any supposed injury, he would then be liable to the punishment awarded by the laws to his crime." ("Brit. and For. Med. Rev.," July, 1843, p. 273.)

It would appear that the law, as thus laid down, in order to render a man responsible for crime, looks for a *consciousness of right and wrong*, and a *knowledge of the consequences of the act*; while the administration of justice rests on the principle that every one knows the law and fears its punishment. Thus, the complete possession of reason is not essential to constitute the legal responsibility of an offender; and it is also to be inferred, from the results of several cases, that a man may be

civilly incompetent, but sufficiently sane to be made criminally responsible. The proofs required in the two cases are essentially distinct.

It has been objected to this *legal test*, that it is insufficient for the purpose intended; it cannot, in a large majority of cases, enable us to distinguish the insane homicide from the sane criminal. Many *insane persons* have committed acts which they knew to be wrong, and of the criminality of which they were at the time perfectly conscious. They have been known to murder others, in order to receive the punishment of death at the hands of the law; and, therefore, they must have been conscious of the wrongfulness, or rather of the illegality, of the act which they were perpetrating, and have known that they were committing an offence punishable by the law of man. In short, the criminal nature of the act has often been the sole motive for its perpetration! (“Ann. d’Hyg.,” 1852, vol. 1, p. 363.) It has been suggested, with some truth, that it is rather the imperfect or defective appreciation of the motives to right or against wrong action which leads to crime among the insane, and not the mere ignorance of right and wrong. Most lunatics have an abstract knowledge that right is right, and wrong wrong; but in true insanity the voluntary power to control thought and actions, and to regulate conduct by this standard, is impaired, limited, or overruled by insane motives. A lunatic may have the power of *distinguishing* right from wrong, but he has not the power of *choosing* right from wrong. A criminal is punishable not merely because he has the power of distinguishing right from wrong, but because he voluntarily does the wrong, having the power to choose the right. (Jamieson’s Lectures on Insanity, “Med. Gaz.,” vol. 46, p. 827. See, also, those of Dr. Bucknill, “Lancet,” vol. 1, 1877; and on the relation of insanity to the Criminal Law by Dr. Orange, 1877.)

[Dr. Forbes Winslow, in speaking of the defence of insanity in criminal cases, uses the following language: “When such questions have come before the judicial tribunals of the country, the presiding judge, in his charge to the jury, has invariably referred to the dicta of preceding administrators of the law, and has quoted their definition or description of insanity as an unerring test of the presence of mental derangement in any case in which the malady is alleged to exist.

“How absurd, upon reflection, must such a course of procedure be! Has not our knowledge of the disorders of the mind advanced during the last fifty years? Do we not know more of insanity than our professional brethren did who lived in the days of Coke, Mansfield, and Erskine? If so, how ridiculous it is to cite their opinions, or to bind us down to the authority of men whose information on this subject must of necessity have been extremely limited and circumscribed. The judges of the land appear to have had no settled or clear views on the subject of insanity.”

“After an examination of the cases which have been brought forward in this work, it must be evident that the capability of ‘distinguishing between right and wrong,’ is not an unerring test to which to appeal. A person may be perfectly competent to draw a correct distinction between right and wrong, and yet labor under a form of insanity which ought unquestionably to protect him from legal or moral responsibility.” (“Plea of Insanity,” p. 73.) “The knowledge attained by

men, of a subject which they have grappled all their lives," says Chief Justice Gibson, in *Smith v. Kramer*, 1 Am. Law Reg. 353, "ought surely to prevail against knowledge gleaned from the hornbooks of a profession to which the gleaners did not belong."

The same eminent judge, in the case of *Com. v. Mosler*, 4 Barr, 266, admitted that moral insanity, if established, would relieve the defendant from criminal responsibility. "There may be," said he, in his charge to the jury, "an unseen ligament pressing on the mind, drawing it to consequences which it sees but cannot avoid, and placing it under a coercion which, while its results are clearly perceived, is incapable of resistance. The doctrine which acknowledges this mania is dangerous in its relations, and can be recognized only in the clearest cases. It ought to have been shown to have been habitual, or at least to have evinced itself in more than a single instance. It is seldom directed against a particular individual: but that it may be so, is proved by the case of the young woman who was deluded by an irresistible impulse to destroy her child, though aware of the heinous nature of the act. The frequency of this constitutional malady is fortunately small, and it is better to confine it within the strictest limits. If juries were to allow it as a general motive, operating in cases of this character, its recognition would destroy social order as well as personal safety. To establish it as a justification in any particular case, it is necessary either to show, by clear proofs, its contemporaneous existence, evinced by present circumstances, or the existence of an habitual tendency developed in previous cases, becoming in itself a second nature." The defence was not established in this case, and the prisoner was convicted.

The objection to adhering to the old decisions with reference to the test of criminal responsibility, in the face of the great advance which has taken place in the last fifty years in the scientific knowledge of the subject of insanity, is that juries rather than suffer an insane criminal, whose unsoundness does not come up to the antiquated standard, to be punished in the same manner as if he were sane, acquit him altogether. He is thus turned loose: if his insanity has *not* been real, a criminal escapes; if it *has*, then society is again exposed to the dangerous freaks of a madman. Even if they convict, notwithstanding the actual existence of moral insanity, the lunatic is restrained only during the period of his sentence, and the same result ensues. If judges, instead of "moving in the ruts" of their predecessors, would, as it is the boast of the common law they do, keep pace with the advance of science; if juries were required, as they are in some States, to find the fact of insanity whenever they acquit on this ground; or if, what would perhaps be still better, the jury, as it has been suggested (Whart. & Stillé, "Med. Jur.," § 277), were permitted simply to pass upon the mere fact of the commission of the act, leaving the consideration of the prisoner's sanity for a commission or jury of scientific men, competent to decide so difficult a question; if, whenever the prisoner is acquitted because of insanity, the court should in all cases commit him to a proper asylum, there to remain *until proved before the same tribunal to be entirely restored*; the plea would be much less frequently set up, and would be much more apt to be properly decided if it should be. Criminals would thus be surer of punishment, the really

insane have an opportunity of being restored by proper treatment, and society have the protection which, under the "right and wrong" test, it so often loses. Where the offence is homicide, as Dr. Taylor very properly remarks, the confinement of the prisoner acquitted on the ground of moral insanity, should, for the reasons he mentions, be for life.—P.]

Medical tests.—The *tests* which have been proposed by medical jurists for detecting cases of homicidal mania are as follows:—

1. The acts of homicide have generally been preceded by other striking *peculiarities of conduct* in the person—often by a total change of character.

2. Those persons who are affected with it, have in many instances previously or subsequently attempted *suicide*—they have expressed a wish to die, or to be executed as criminals. These supposed criteria, when tendered as medical proofs of insanity in courts of law, have been repeatedly and very properly rejected. They are of too vague a nature for practical use, and apply as much to cases of moral depravity as of actual insanity; in short, if these were admitted as *proofs*, they would serve as a convenient shelter from punishment for many sane criminals.

3. *Motive for crime.*—The acts are without *motive*; they are in opposition to all human motives. A man known to have been tenderly attached to his wife and children murders them—a fond mother destroys her infant. It is hereby assumed or implied that persons who are sane, never commit a crime without an apparent motive, and that in the perpetration of a criminal act an insane person either never has a motive, or has one of a delusive nature only. If these propositions were true, it would be easy to distinguish a sane from an insane criminal; but the rule wholly fails in practice. In the first place, the non-discovery is here taken as a proof of the non-existence of a motive; while it is undoubted that motives may exist for many atrocious criminal acts without our being able to discover them—a fact proved by the numerous recorded confessions of criminals before execution, in cases in which, until these confessions were made, no motive for the perpetration of the crime had appeared to the acutest minds.

4. *Confession.*—The subsequent conduct of the person: he seeks no escape, delivers himself up to justice, and acknowledges the crime laid to his charge. This is commonly characteristic of homicidal mania; for by the sane criminal every attempt is generally made to conceal all traces of the crime, and he denies it to the last, or until he sees that denial can be no longer serviceable to him.

5. *Accomplices.*—The sane murderer has generally *accomplices* in vice or crime; the homicidal monomaniac has not. Upon this it may be observed that some of the most atrocious murders committed in modern times have been proved to be the acts of persons who had neither accomplices nor any assignable inducements leading to the commission of the crimes. It is, however, a fact so far in favor of the existence of homicidal insanity, that the *insane* never have accomplices in the acts which they perpetrate. These criteria can hardly be described as medical; they are circumstances upon which a non-professional man

may form just as safe a judgment as one who has made insanity a special study.

6. *Delusion in the act.*—The presence of *delusion* has been said to characterize an act of homicidal monomania, while premeditation, precaution, and concealment have been considered to be the essential features of the act of a sane criminal. Some medical men think, if they discover anything resembling a delusion in the mind of an accused person, that he is necessarily irresponsible for the act, but the theory of the law, as laid down by the judges in *M'Naughten's* case, is, that notwithstanding a person labors under a delusion, if he commits an act which he knows to be contrary to law, he is liable to punishment; if the delusion be *partial*, the party accused is still responsible; and if the crime were committed for an imaginary injury, he would be held equally responsible. (See p. 840, *ante*.) Much stress was formerly laid upon the *delusion being connected with the act* in cases of alleged insanity; but it must be remembered that, except by the confessions of insane persons during convalescence, it is not easy for a *sane mind* to connect the most simple acts of a lunatic with the delusion under which he is laboring. Every act of a homicide perpetrated by a really insane person is doubtless connected with some delusion with which he is affected; but it is not to be supposed that one who is sane can always discover this connection.

It may be further observed that premeditation, precaution, concealment, and flight are met with in crimes committed by both sane and insane criminals, although these acts are certainly strong characteristics of sanity. It should be a question for a jury whether, when they are proved to have existed in any criminal act, there might not have been such a power of self-control in the person, although in some degree insane, as to justify a conviction. It is not the presence of a slight degree of mental aberration which necessarily indicates a loss of power of controlling actions. Are such persons less beyond the influence of example than one-half of the same criminals who are punished?

7. *A number of murders perpetrated at once.*—In the acts of sane criminals one person, or at the most two, may be destroyed; but, in cases of homicidal mania, it is not unusual to find a wife and several children killed by the husband, or four or five children at once destroyed by the wife. In these cases no motive but that which is based on some insane delusion, can be suggested for such a series of murders. Thus, four infants may be found murdered by a mother, who admits the act but endeavors to account for it by asserting that she wished to convert them into angels, or to save them from destitution and exposure to worldly temptations.

It would be wrong, however, to infer from this statement that because a man has heaped crime upon crime, he is therefore insane. This would be equal to making the atrocity of the crime or crimes a test of insanity. In the case of Southey (*Reg. v. Southey*, Maidstone Winter Assizes, 1865), it was proved that the prisoner, a man of wicked and depraved habits, had destroyed three of his children in London, and had then proceeded to Ramsgate, and there deliberately destroyed his wife and another child. He pretended to justify these five murders, and wished

to make it appear that he was insane. In regard to this man's conduct through life, nothing but moral depravity was proved. Still he found medical defenders who brought forward as proofs of "delirium," statements which clearly showed that they did not understand the meaning of the term. It was admitted that if the man had committed one of the murders, he might have been sane, but having committed five in succession, he was insane and incompetent to judge of the nature of his acts! The fallacy of such an argument needs no exposure. There could be no doubt of the sanity of *Rush*, who was tried and convicted of the murder of three persons at the same time (Norwich Lent Assizes, 1849). Thinking that he had a legal claim to an estate held by a Mr. Jermy, the prisoner went to the house, concealing his features with a mask, and there shot one after the other, Mr. Jermy, his son, his son's wife, and a maid-servant, killing three of them. The defence of insanity was not set up. He was properly convicted and executed.

Summary.—The foregoing considerations lead to the inference that there are *no certain legal or medical tests or characters* whereby homicidal mania can be demonstrated to exist. Each case must be determined by the circumstances attending it: but the true criterion of irresponsibility in all ambiguous cases appears to be, whether the person, at the time of the commission of the crime, had or had not a *sufficient power of self-control to govern his actions*; or, in other words, whether he knew the act was wrong, and could avoid the perpetration of it: or, as Sir Fitzjames Stephen more concisely puts it, there should be proof of an *absence of the power of self-control*, caused by *disease* affecting the mind. This involves the consideration, not only whether insanity existed in the accused, but whether it had reached such a degree as to destroy, not merely a consciousness of the nature of the act, but volition—the will to do or not to do it. If from circumstances it can be inferred that an accused person had this power, whether his case falls within the above rules or not, he should be made responsible and rendered liable to punishment. If, however, he was led to the perpetration of the act by an *insane* impulse, or, in other words, by an impulse which his mental condition did not allow him to control (*lésion de volonté*, Esquirol), he is entitled to an acquittal as an irresponsible agent. The power of controlling an act appears to me to imply the existence of such a state of sanity as to render the party responsible: and when there is this want of control, it may be fairly concluded that there is no sane intention, and that the person is irresponsible. A test somewhat similar to this is constantly applied by juries, under the direction of our judges, to distinguish murder from manslaughter; and it is quite certain that sanity and homicidal mania are not more nicely blended than those shades of guilt whereby manslaughter passes into murder. The manner and circumstances under which a crime is committed will often allow a fair inference to be drawn as to how far a power of self-control existed or was exercised. A man in a violent fit of mania or delirium rushes with a drawn sword into an open street, and stabs the first person whom he meets; another, worn out by poverty and destitution, murders his wife and children to prevent them from starving, and then probably attempts to destroy himself—these are cases in which there is a fair ground to entertain a plea

of irresponsibility. But when we find a man, not showing any previous intellectual disturbance, lurking for many days together in a particular locality, having about him a loaded weapon,—watching a particular person who frequents that locality,—not facing the individual and shooting him, but coolly waiting until he has an opportunity of discharging the weapon unobserved by his victim or others,—the circumstances appear to show such a perfect adaptation of means to ends, and such a power of controlling actions, that it is difficult to understand on what principle an acquittal on the ground of insanity could have been allowed. I refer here to the case of *M'Naughten*, tried for the murder of *Mr. Drummond*, January, 1843. The acquittal in this case was the more remarkable because there was no proof of general insanity, and the crime was committed for a supposed injury. According to the rules laid down by the fifteen judges, from questions submitted to them in connection with this case, this man should certainly have been convicted (*ante*, p. 840). These acquittals on the ground of insanity, contrary to public opinion, are often erroneously ascribed to the crotchets of medical experts. They are, I believe, more commonly due to the powerful and impassioned addresses of counsel, who in civil as well as in criminal cases simply fight for victory, wholly irrespective of any abstract ideas of truth or justice. Medical opinions are brought forward or suppressed in order to complete a sensational picture, which is intended to show to an ignorant jury, either that a lunatic is perfectly sane, or that a sane man who has committed a deliberate act of murder, is beyond any reasonable doubt insane. Every artifice of argument which may raise a doubt in the minds of the jury is resorted to on these occasions, and the last words of the last eloquent speaker have a far greater influence on the verdict than the opinions of "mad doctors" in the witness-box. These admit of being misrepresented and turned into ridicule without any power of reply on the part of those who gave them. [Dr. Bucknill (*Criminal Lunacy*, 98, 99) mentions the case of *Margaret Garrety*, who was tried in 1851, at Newark, New Jersey (see "*Am. Journ. Ins.*," January, 1852) for "the assassination with a carving-knife, of a young man who had seduced her and afterwards married another woman. This trial," he says, "presents a remarkable instance of perversion of the plea by the jury, in order to avoid the condemnation and execution of an ill-used woman. The jury were sixty-two hours in deliberation; their verdict of 'not guilty, on the ground of insanity' was greeted with applause in the court-house, and with universal congratulation and rejoicing in the city. The celebrated Hampshire verdict, 'served him right,' would perhaps have been more consistent, if not with the facts of the case, at least with the temper of the public. After the trial, the court appointed a commission consisting of six physicians, to examine her case, and decide whether she should be sent to the asylum or set at liberty. They unanimously reported, that after careful investigation, they found existing no evidence of unsound mind."—P.]

In cases of alleged homicidal mania very vague meanings have been sometimes assigned to the term *delusion*. In *Reg. v. Burton* (Maidstone Lent Assizes, 1863), the prisoner, a youth of 18, was indicted for the murder of a boy at Chatham. There was no motive, but it was ar-

gued by his counsel in defence, that he labored at the time under a delusion—the delusion being a desire to be hanged. Mr. Joy, the surgeon of the prison, stated that he had had frequent opportunities of examining the prisoner while in gaol, and in his opinion he was perfectly sane; so far as witness could judge, he was under no delusion. The jury returned a verdict of “guilty.” If the youth had believed that he had been already hanged for murder, this might have been considered a delusion; but a desire to be hanged or to die from any violent cause cannot be so regarded. The remarks of the learned judge (the late Mr. Justice Wightman) upon this kind of defence, contain all that is necessary to show its fallacy. In passing sentence upon the prisoner he said, “It is stated that you had labored under a morbid desire to die by the hands of justice, and that for this purpose you committed the murder. This morbid desire to part with your own life can hardly be called a delusion; and, indeed, the consciousness on your part that you could effect your purpose by designedly depriving another of life, for which you knew you would have to suffer the punishment due to the greatest of crimes, shows that you were perfectly able to understand the nature and consequences of the act which you were committing, and that you knew it was a crime for which, by law, the penalty was capital. This was, in truth, a further, and I may say a deeper, aggravation of the crime; for you designedly intended to compass your own death by the murder of another.”

It has been a disputed question whether a medical witness on a trial in which a defence of insanity is raised, can be asked his opinion from the evidence, respecting the state of a prisoner's mind at the time of the commission of the alleged crime, *i. e.*, whether the accused was conscious at the time of doing the act that he was doing something contrary to law, or whether he was then laboring under any and what delusion. It has been decided, by fourteen judges out of fifteen, that facts tending to lead to a strong suspicion of insanity must be proved and admitted before the opinion of a medical witness can be received on these points. (See “Med. Gaz.,” vol. 46, p. 240.)

In forming a judgment of the mental condition of an accused person, it is no part of the province of a witness to modify his opinion according to the *punishment* which may follow if the plea be rejected; he should simply base it on the medical *facts* of the case. The legislature only is responsible for the punishment adjudged to crimes. The late Dr. Mayo has justly observed that a medical witness is summoned to a court of justice in order to enable the judge and jury to arrive at certain practical conclusions. The question proposed to him involves a simple fact, and not its consequences; and if the latter consideration be entertained by him, it will be liable to bias his evidence on the fact, which is his legitimate topic. The definition of insanity becomes very expansive when its expansion may become protective to a criminal with whom we may happen to sympathize. The question whether the accused is a responsible agent, is of a judicial nature; our evidence should be confined to the question whether the accused is *insane* in a certain sense or meaning in which it was understood and defined by law. (“Medical Testimony and Evidence in Cases of Lunacy,” 1854, p. 9.) A medical witness in

these cases generally moulds his evidence to a foregone conclusion on the criminal responsibility of the accused, and he thus lays himself open to a remark from the judge that he must not encroach on the functions of the jury. It is certainly a great evil that, under the present mode of laying this question before a jury, the law operates unequally. One case becomes a subject of prominent public interest, and every exertion is made to construe the most trivial eccentricities of character into proofs of insanity, and to magnify the effects of an hereditary tendency, by proving that a maternal grandmother's sister, or a still more remote relative, had been confined as a lunatic ;—an acquittal follows. Another case may excite no interest,—it is left to itself ; the accused is convicted, and either executed or otherwise punished, although the evidence of insanity, had it been as carefully sought for and brought out, would have been perhaps stronger in this than in the former instance.

The doctrine of "irresistible impulse" and the theory of impulsive insanity, have been strained in recent times to such a degree as to create in the public mind a justifiable distrust of medical evidence on these occasions. It is obviously easy to convert this into a plea for the extenuation of all kinds of crimes for which motives are not at once apparent, and thus medical witnesses often expose themselves to severe rebuke. They are certainly not justified in setting up such a defence, unless they are prepared to draw a clear and common-sense distinction between impulses which are "unresisted" and those which are irresistible. As a learned judge once remarked in his address to a jury: "What is the meaning of not being able to resist an impulse? Every crime is committed under an impulse, and the object of the law is to compel persons to control or resist these impulses. If it is made an excuse for a person who has committed a crime, that he was goaded to it by some impulse which medical men might choose to say *he* could *not* control, such a doctrine would be fraught with very great danger to society."

While the truth of these remarks is obvious, it must be admitted that the ordinary legal test for responsibility is not satisfactory. In addressing the jury in *Reg. v. Cockroft*, involving a trial for murder (Leeds Autumn Assizes, 1865), Mr. Justice Mellor made the following observations on the defence of insanity which had been set up: "It would be dangerous if the idea went abroad that persons committing crime under sudden impulse were therefore to be excused. At the same time, he thought that the definition of insanity which would excuse from criminal responsibility, as given in M'Naughten's case, hardly went far enough. He was of opinion that a man might know that he was doing an act which was wrong, and still he might be laboring under such disease of the mind as not to be able to restrain his impulse to do that act, and he should therefore not be amenable to the criminal law. The mere fact, however, of the prisoner being ignorant, and of a low type of mind would be no excuse. If the jury thought that the prisoner knew at the time when he committed the act that he was doing wrong, and was not laboring under such a disease of the mind as incapacitated him from controlling his impulses, he was not entitled to acquittal on the ground of insanity. The doctrine of uncontrollable impulse, as laid down by some writers, was a very dangerous one, and required to be watched with the utmost

care. Passion arising from provocation, however trivial, offered to a mind however ill regulated, did not relieve the person from criminal responsibility."

Hence it follows that a man might know that he was doing wrong and committing an act against the law of God and man, yet if with this consciousness of the illegality of the act, there was a *diseased condition of mind* which prevented him from controlling his actions, he will be entitled to an acquittal on the ground of insanity. With this admission it appears to me unnecessary to occupy space with metaphysical discussions regarding criminal responsibility: for however objectionable the theory, if the *practice* of the law be in any one case in conformity with that which has been advised by writers on the Medical Jurisprudence of Insanity, although it may be even adverse to the theory on which it is professedly based, this is all with which we have to concern ourselves:—the principle is admitted. The great defect in the English criminal law is, not that it will not go even to the full extent of exculpating a person who has committed a crime with a knowledge of its illegality, and under what is called by medical men an "uncontrollable impulse," or an impulse which owing to mental disease his reason was not sufficient to control,—but the *uncertainty of its application*. There are many cases reported which show that an acquittal on the ground of insanity in a trial for murder, is frequently a mere matter of accident.

Since the publication of the former edition of this work, numerous trials for murder have taken place, in which there have been acquittals on the ground of insanity, and the accused confined during her Majesty's pleasure. In some of these epilepsy has been associated with insanity. The details of these cases present no striking difference from those recorded in the text, with the exception of one, in which a man who had been a lunatic and had recovered was tried on a charge of murder, and acquitted on the ground of insanity (*Reg. v. Blampied*, Maidstone Summer Ass., 1875). The prisoner was charged with the wilful murder of a man named Catt, who was a fellow-laborer with him in the dock-yard at Chatham. Blampied became insane in December, 1868, was confined in a lunatic asylum, from which he was discharged as cured in December, 1872, and had ever since worked at his trade in a proper manner. The deceased man was often associated with him, and some months previously a quarrel had taken place between them, but it was not serious, and they were apparently on friendly terms. In April, 1875, they were working within six feet of each other, when the prisoner, without any known provocation, struck the deceased violently with an adze on the back of the head, fracturing his skull and causing his death. The man pleaded not guilty, with every appearance of sanity. In the defence it was urged that he was not responsible for the act on the ground of insanity. The learned judge, Mr. Justice Brett, told the jury that the law took no heed of sanity or insanity abstractedly considered, or of the presence or absence of delusions. To exempt from responsibility, a man must be so mad as not to know the nature of the act he committed. If he knew what he was doing, and if he knew that it was wrong, then, however mad he might be, he was still responsible. He also remarked that for three years previously the prisoner had been sane, and had been treated

as sane by his associates. These remarks pointed clearly to a conviction, but the jury, after consulting for a short time, found a verdict of guilty, but that the prisoner was not accountable for his acts; in other words, they acquitted him on the ground of insanity. This shows that on these occasions a jury may decline to accept the legal rule of responsibility as here laid down, and act upon their own judgment.

From the number of acquittals which annually take place on the ground of insanity, it will be understood that Broadmoor and other county asylums have a large population of criminal lunatics. In November, 1877, there were 487 in Broadmoor alone, and among these there were six men and eight women who, in the opinion of the medical superintendent, were quite *sane*! All but one of these had committed murder. In spite of their proved sanity, the case of *Blampied* above related shows what dangers might accrue to the public by their liberation. (See pp. 807, 832.)

CHAPTER LXVII.

SUICIDAL MANIA.—SUICIDE NOT NECESSARILY AN INDICATION OF INSANITY.—SUICIDE A FELONY.—IN RELATION TO LIFE-INSURANCE.—PUERPERAL MANIA.—PYROMANIA.—KLEPTOMANIA.—EROTOMANIA.—DIPSOMANIA.—RESPONSIBILITY OF DRUNKARDS.—DELIRIUM TREMENS.—SOMNAMBULISM.—THE DEAF AND DUMB.

Suicidal monomania, or suicidal mania, is the name given to that form of insanity which is marked by the prominent idea of self-destruction. Its approach is insidious; it is foreshadowed by impaired appetite and sleeplessness arising from some cause of mental anxiety too trivial to create alarm. It may proceed either from sudden impulse, or be the result of long deliberation; it may be committed with, or without, apparent motive; it may proceed either from a delusive or a real apprehension of poverty, disgrace, or ruin. Suicide from sudden impulse is not uncommon; persons have been known to destroy themselves who had not previously manifested any symptoms of *intellectual* disorder. Sir Charles Bell relates that one of the surgeons of the Middlesex Hospital was in the habit of going every morning to be shaved by a barber in the neighborhood, who was known as a steady industrious man. One morning the surgeon was conversing with the barber about an attempt at suicide which had recently occurred, and the surgeon observed that the man had not cut his throat in the right place. The barber then inquired, casually, where the cut should have been made; the surgeon pointed on his neck to the situation of the carotid artery. The barber in a few minutes retired to the back of his shop, and there cut his throat with the razor with which he had been shaving the surgeon; he had wounded the carotid artery in the place indicated by the surgeon, and died before any assistance could be rendered to him. Although this act was quite

sudden and unexpected, it may have been only the final result of a delusion which had long existed, concealed from others, in the mind of this man—just as the sight of a weapon has often led to its use for the purpose of suicide.

Dr. Forbes Winslow remarks "that a person is oftentimes impelled to self-destruction by the overpowering and crushing influence of a *latent* delusion that has for weeks, and perhaps months, been pressing like an incubus on his imagination. Patients sometimes confess that they have been under the influence of monomaniacal ideas and terrible hallucinations for a long period without their existence being suspected even by their most intimate associates. "For six months," writes one patient, "I have never had the idea of suicide, night or day, out of my mind. Wherever I go an unseen demon pursues me, impelling me to self-destruction! My wife, friends, and children observe my listlessness and perceive my despondency, but they know nothing of the worm that is gnawing within. Is this not a type of cases more generally prevalent than we imagine?" ("Obscure Diseases of the Brain," p. 265.) The want of power to shake off this delusion shows clearly that the mind is not in a healthy state—that the person is not sane.

Men who are thus mentally affected generally retain a certain control over their actions; thus they will voluntarily give up pistols, razors, or other weapons by which suicide might be perpetrated. A friend suffering from an attack of suicidal mania, while residing with me in Paris in 1830, delivered to me one night his razors, with a request that I would lock them up and keep them out of his sight, as otherwise he feared that he might destroy himself at any moment. Although he recovered from this attack, he had a relapse, and subsequently destroyed himself by taking prussic acid. Persons laboring under this form of monomania, may go to bed perfectly collected, and suddenly awake in the night and destroy themselves by hanging, drowning, or precipitating themselves from a window. These cases probably depend on the persistence of some horrible hallucination which may have occurred in dreaming, and in the reality of which they cannot at the time disbelieve. Some years ago I saw a case of this kind in a man who was a patient at Guy's Hospital. The man attempted to strangle himself in the dusk of the evening with the cord of his bed; he was fortunately saved, and he recovered after having been nearly strangled. On asking him what led him to the attempt, he told me that he suddenly saw a large black figure round his bed (the devil), which by signs and words compelled him to try and hang himself. It appeared that this man had previously shown symptoms of suicidal monomania.

When the impulse to suicide is checked by any great moral shock, it may suddenly disappear. My friend, to whose case I have above referred, recovered under the shock from the sudden outbreak of the French Revolution in 1830. The danger to which he was exposed, while residing with me in Paris in the early days of the revolution, for a time at least dispelled the idea of self-destruction. Pinel mentions the case of a man who, while hurrying to one of the bridges of Paris to throw himself into the river, was suddenly attacked by robbers; he made a desperate resistance, and escaped from them. He could not then account

for his being where he was, and quietly walked he the intention of destroying himself. There is but acts of suicide would be prevented if circumstances opportunity for reflection; the mind would then dominating idea of self-destruction.

Suicidal mania is susceptible of being spread when the mode of self-destruction adopted is instances of a horrible kind, or by such as excite sight of a particular spot where an act of suicide committed will often induce a person, who may hitherto be supposed of any such disposition, to destroy himself. A third suicide took place from the Monument near after the first had occurred. Acts of incendiariness served to lead to arson in the same, or in a neighborhood is here a criminal as well as a monomaniacal imbecile has clearly shown that there is no check so effectual as the application of the law.

Does the act of suicide necessarily indicate the insanity?—Suicide is often set down as furnishing positive evidence of a doctrine which commonly finds expression in the law of juries—not so much from the fact of insanity being proved as that any verdict but this would weigh heavily against the accused on his surviving relations and friends.

In the opinion of Dr. Davey, the suicidal propensity is, under all circumstances, a positive sign of insanity. ("Journal of Mental Science," 1844, p. 100.) This, however, is not in accordance with the views of many writers. In one case, a person will fancy that he is constantly oppressed and persecuted by all around him, and his life and affairs are ruined, when, on the contrary, his affairs are flourishing; he destroys himself under this delusion, incurring many evils. In cases of this description, whether the act is from delusory insane impulse, or from delusive reason, it is very doubtful that the act is one of insanity. It is very difficult to find a real motive is obviously present—as when a person seeks to avoid actual disgrace or impending ruin. The motive is not really—on a real estimate of the man's position; it is foreseen, and the suicide calculates that the loss of life is a smaller evil than the loss of honor and fortune. A motive of this kind is itself delusive, and will apply to the minds of most men; but what known motive is there for parricide, infanticide, or any other crime of the kind? It appears to me, we must allow either that all crimes are the result of insanity, or that suicide, like infanticide, may be committed by a sane person. To affirm that suicide is always *per se* evidence of insanity is to affirm, substantially, that there is no criminal act which is not insane delusion. (See "Ann. d'Hyg.," 1844, p. 100.) for some additional remarks on this subject see

son, "Med. Gaz.," vol. 46, p. 523, and "Jour. Psychol. Med.," 1850, p. 19.)

The law of England very properly treats suicide as a felony; those who have attempted and failed in its perpetration are held to be sane and responsible agents, unless there should be clear evidence of their (intellectual) insanity from other circumstances; and it is certain, that the evidence required to establish this, must be much stronger than that sometimes admitted in cases of homicide.

Some singular medico-legal cases have occurred, involving the question how far the act of attempting suicide is indicative of insanity. In the case of the *Queen v. Rumball* (Cent. Crim. Court, May, 1843), a woman was charged with attempting to drown her child. It appeared in evidence that she had fastened her child to her dress, and thrown herself into a canal with the intention of destroying herself. She was rescued, and was subsequently tried and convicted of the felony of attempting to murder her child by drowning. Had she not been rescued, and had she succeeded in her purpose of self-destruction, it is probable that the verdict of a jury would have been, as it so frequently is on these occasions—"Temporary insanity." In *Reg. v. Furley* (Cent. Crim. Court, April, 1844), the prisoner was convicted of murder under similar circumstances, but the sentence was subsequently commuted. In *Reg. v. Gathercole* (1839), a man was charged with manslaughter under the following singular circumstances: The prisoner threw himself into a canal for the purpose of drowning himself; the deceased, who was passing, jumped in and rescued him, but by some accident he was himself drowned in the humane attempt. The defence was, that the prisoner was at the time insane, and therefore not responsible for the death of the person who attempted to save him; but this was negatived, and the prisoner was convicted. So if a man intending to shoot himself fails, and by accident shoots a bystander, he will be held responsible, unless there be a clear proof of intellectual insanity; the act—the attempt itself, taken alone, will not be admitted as evidence.

If two persons agree to commit suicide, and one only dies, the survivor is guilty of murder. In *Reg. v. Fisher* (Taunton Spring Assizes, 1865), the prisoner was indicted for the murder of his wife by poison. It appeared from the evidence that they had been married fourteen years, and lived happily together. The man was well-conducted and industrious; but he fell into a desponding state of mind, and thought that by the introduction of machinery into his trade of a shoemaker, he and his wife would be reduced to poverty. He communicated this feeling to his wife; they pondered over it together, and they both agreed to destroy themselves. The man procured a quantity of laudanum, and shared it with his wife; they took about an ounce each. The wife died, but owing to early vomiting the prisoner recovered. It was proved that before marriage the prisoner had been confined in a lunatic asylum; still he had perfectly recovered, and just before this occurrence it was observed that both husband and wife were low and dispirited. There was then no indication of intellectual insanity about him; and the only delusion appeared to be that machinery would ruin his trade. In answer to the charge he said: "According to my notion I am not guilty of mur-

der." The case is like that of many others—of two poor, weak-minded, infatuated people agreeing to commit suicide. Under the direction of the judge, the jury returned a verdict of guilty.

Suicide in relation to life-insurance.—It is well known that according to the rules of some English offices, a policy of life-insurance is forfeited by the act of suicide; but supposing it to have been really an act of insanity, it has been doubted whether the policy would be legally forfeited. In an equitable view the policy should not be forfeited under these circumstances, any more than if the party had died accidentally by his own hands. The condition equitably implies that the assured party puts himself to death *deliberately* and not unconsciously through a delusion as a result of a fit of delirium or an attack of insanity. This question was raised in the case of *Borradaile v. Hunter* (Dec. 1841). An action was brought to recover the amount of a policy of insurance effected on the life of a clergyman who threw himself into the Thames from Vauxhall Bridge, and was drowned. The whole case turned upon the legal meaning of the words, "*die by his own hands*," which formed the exception in the proviso to the payment of the policy. At the trial of the case, Erskine, J., directed the jury, that if the deceased threw himself into the river knowing that he should destroy himself, and intending to do so, the policy would be void; they had further to consider whether the deceased was at the time capable of distinguishing between right and wrong, or, in other words, whether he had sufficient knowledge of the consequences of the act to make him a *felo-de-se*. The jury found that the deceased threw himself into the water intending to destroy himself, and that previously to this act there was no evidence of insanity. They were then directed to take the *act itself* with the previous conduct of the deceased into consideration, and say whether they thought he was at the time capable of knowing right from wrong. They then found that he threw himself from the bridge with the intention of destroying himself, but that he was not then capable of judging between right and wrong. The jury were here evidently perplexed with the strict meaning of the words right and wrong; the first part of the verdict made the case one of *felo-de-se*, the last part made it one of insanity. The verdict was entered for the defendants, *i. e.*, that the deceased was a *felo-de-se*, and that the policy was therefore void.

This case was subsequently argued before the four judges in the Common Pleas (May, 1843). It was then contended for the plaintiff that, according to the terms of the policy, there must have been an *intention* by the party assured to "die by his own hand," and that an insane person could have no controllable intention. The judges differed; three thought there was no ground for saying that the deceased was affected by an uncontrollable impulse; on the contrary, the jury had found that he threw himself into the river knowing that he should destroy himself, and intending to do so. In their opinion the act was one of *felo-de-se*, and the policy was void. Tindal, C. J., considered that the verdict should be for the plaintiff, thereby leading to the inference that the act of suicide was in this case the result of insanity, and not of a felonious killing, to which alone he considered the exception in the proviso should apply. It is probable if the term "*suicide*" had been inserted in the

policy, instead of the words "*die by his own hands*," that the decision would have been in favor of the plaintiffs; for to vitiate a policy from an accidental result depending on an attack of insanity and *flowing directly from that attack*, is virtually vitiating it for the insanity itself! In this respect, it appears that the learned Chief Justice took a sound and equitable view of the question, so important to the interests of those who have insured their lives. It is impossible for a man to enter into a contract *against an attack of insanity*, any more than against an attack of apoplexy! The jury found that the deceased was irresponsible for the act, and it is clear that the insurers and insured intended no more by using the terms "*die by his own hands*," than the act of suicide. By this decision, therefore, the insurers received the benefit of a wider interpretation of the terms than that which either party could have foreseen or contemplated.

The question was again raised in the case of *Schwabe v. Clift*, Liverpool Summer Assizes, 1845. ("Med. Gaz.," vol. 36, p. 826.) The deceased, whose life was insured, destroyed himself by taking sulphuric acid: there was clear evidence of his being at the time in a state of insanity. The jury here, under the direction of Creswell, J., returned a verdict for the plaintiffs, thereby deciding that the policy was not vitiated by the mere act of *suicide*. The learned judge held that to bring the case within the terms of the exception, the party taking his own life must have been, at the time of the act, *an accountable moral agent and able to distinguish right from wrong*. In this instance the term used in the policy was "*suicide*," which according to the learned judge meant "*a felonious killing*." Supposing that the insured party was killed by voluntarily precipitating himself from a window while in a fit of delirium from fever, this would be an act of suicide, or dying by his own hand; but it surely cannot be equitably contended that his heirs should lose the benefit of the insurance in consequence of an event depending on an accidental attack of a disease, which no one could have foreseen, and against which no one could guard! If this principle be not admitted, the decision which must necessarily follow would appear to be against all equity; if it be admitted, then it must apply equally to every case of mental disorder, the proof of the existence of this resting with those who would benefit by the policy.

On an appeal, the judgment in this case was, however, reversed, the judges again differing. It was argued for the insurers, that if a man retained just enough of intelligence to produce death by competent means, but was deprived of all *moral sense*, the policy was void. Against this view it was urged by one of the judges, that whether the intellect was destroyed altogether, or only partially, it could make no difference. If death was the result of disease, whether by affecting the senses, or by affecting the reason (thus leading to suicide), the insurance office was liable under the policy. If the act was not the act of a sane and reasonable creature, it was not an act of suicide within the meaning of the proviso. Those judges who adopted the opposite view held that the meaning of the words, as introduced into the exception, was—if the party should kill himself *intentionally*: the words were considered to include all cases of voluntary self-destruction. If a party voluntarily

killed himself, it was of no consequence whether he was sane or not. The majority of the court held this view, and a new trial was granted. Had all the judges been present to give their opinions, the decision might have been different; for five had expressed themselves at various times in favor of the view that the term suicide in policies applies, as it ought to do, only in cases in which there is no evidence of insanity; while four had declared their opinion to be, that it includes all cases of "intentional" self-killing, whether the person be sane or insane. It is difficult to understand how a man in a fit of delirium or insanity can be said to kill himself voluntarily or intentionally. Will and intention imply the judgment of a sane man in regard to civil and criminal acts, but a delirious or really insane person acts under a delusion; and as the law would hold him irresponsible in regard to others, his representatives should not suffer for an act which he was himself incapable of controlling. (See "Law Times," July 18, 1846, p. 842.)

The decision in this case is of great importance to persons whose lives are insured, for it may be made to govern others; and on this principle, a man attacked with delirium, and who during the fit precipitated himself from a window and was killed, would be declared a suicide within the meaning of the proviso, and a policy of insurance on his life would be *ipso facto* void. It will be perceived that the law, as interpreted by a majority of the judges, is that whenever a person destroys himself intentionally, whatever may be the state of his mind, the policy becomes void. It also appears that, according to this legal view of the question, a person may have and exercise his intention, although undoubtedly insane. Whether he has been found so under a commission, or a verdict to this effect has been returned by a coroner's jury, is therefore unimportant. It must be proved by those who would benefit by the policy, that the party died from his own act without *intending* to destroy himself. If a man take poison, or shoot himself, or commit any other act leading to his own death, it must be shown that it was the result of *accident*, and not of design on his own part. Some insurance offices now insert in the contract a proviso by which, whether the person be found *felo-de-se* or not, the policy shall be forfeited; but they reserve to themselves the power of returning a part or the whole value of the policy, calculated up to the day of death. In the mean time they have the power of taking the full benefit arising from an act of suicide committed during a fit of delirium or insanity, in which, as medical men know, there can exist no controllable intention, no freedom of judgment, and no real exercise of will. (See case "Prov. Med. Journ.," Aug. 9, 1818, p. 428.) [See chap. on Life Insurance, post.]

There is a form of suicide not unlikely to present itself for consideration, namely, where a man, in the habit of using a powerful drug for medicinal purposes, takes a large dose while in a state of intoxication, and dies. In May, 1857, a *Mr. George Fife* died from an overdose of morphia, and it was proved to the satisfaction of the jury that this must have been taken while he was intoxicated. In such a case, a man may have no sane intention of destroying himself, yet he dies by his own hands. As drunkenness does not excuse or justify any act of homicide, so it would not probably be allowed to affect the question of suicide; and

death under such circumstances would probably be held to be a felonious killing.

From these cases one fact is clear—the act of suicide is not treated by the law as a necessary *proof of insanity*; and therefore the ingenious arguments which have been held on this subject have but little interest for a medical jurist, in a practical view. It has been elsewhere stated that acts of suicide have been mistaken for homicide, merely because the deceased had expressed no *intention* of destroying himself, and had manifested no disposition to the act by his previous conduct. This, however, is a fallacious view of the subject, since suicide from sudden impulse is by no means unfrequent; and even when the act bears about it marks of deliberation, it is not to be expected that a person should previously announce his intention, for this would be a sure way of defeating his object.

If, as it is alleged, the act of suicide was in all cases the offspring of insanity, suicide should be frequent among the insane. Experience, however, is not in favor of this assumption. The Report of the Commissioners of Lunacy for 1850 shows that there were then confined as lunatics 15,079 persons, while the suicides for the year among this large number amounted to only eight, of which six were perpetrated by strangulation. As mechanical restraint is either abolished, or considerably diminished in most asylums, lunatics have now much more liberty than formerly, and yet suicides among them are comparatively rare. This favorable result must be in part ascribed to active superintendence and watching.

The tendency to suicide seems to be in some cases hereditary; Dr. Burrows relates an instance in which this propensity declared itself through three generations; in the first, the grandfather hanged himself; he left four sons; one hanged himself, another cut his throat, and a third drowned himself in an extraordinary manner, after having been some months insane; the fourth died a natural death,—which, from his eccentricity and irregularity of mind, was scarcely to be expected. Two of these sons had large families: one child of the third son died insane, two others drowned themselves, another became insane, and made the most determined attempts on his life. Several of the progeny of this family, being the fourth generation, when they had arrived at puberty, showed a tendency to the same fatal propensity.

Puerperal Insanity.—Mania may present itself in other forms than those hitherto considered. Women who have been recently delivered are liable to sudden attacks, in which a disposition to murder their offspring is the most marked symptom. This has been long known and recognized by physicians as “puerperal mania.” The disorder seldom attacks a woman before the third day,—often not for a fortnight, and in some instances not until several weeks after delivery. Out of ninety-two cases, the late Sir James Simpson observed that the attack occurred in twenty-one between the fifth and the fifteenth day. (“Med. Times and Gaz.,” Sep. 1, 1860, p. 201.) The most frequent period is at or about the commencement of lactation, and between that and the cessation of the uterine discharges (lochia). According to Esquirol, it is gene-

rally preceded or attended by a suppression of the lochia and milk. The late Dr. Ashwell remarked that undue lactation might give rise to an attack of mania, under which the murder of the offspring might be perpetrated. ("Diseases of Women," p. 732. See the case of *Reg. v. Lacey*, Nottingham Summer Assizes, 1858.) It may also come on after forced or voluntary weaning.

The *symptoms* do not differ from those of mania generally, but it may assume any of the other forms of insanity; and in one-half of the cases, it may be traced to hereditary tendency. There is a childish disposition for harmless mischief. The woman is gay and joyous, laughing, singing, loquacious, inclined to talk obscenely, and careless of everything around. She imagines that her food is poisoned; she may conceal the suspicion, and merely avoid taking what is offered to her. She can recognize persons and things; and can, though perhaps she will not, answer direct questions. Occasionally there is great depression of spirits with melancholia. These facts are of some importance in reference to cases of alleged child-murder. This state may last a few hours, or for some days, or weeks. The murder of the child is generally either the result of a sudden fit of delirium, or a sudden impulse, with the full knowledge of the wickedness and illegality of the act; so that the legal test of responsibility, *i. e.*, a knowledge of right and wrong, cannot be strictly applied to such cases as these, except on the assumption that insanity already exists and affects the consciousness of the individual. A woman has been known to request her attendants to remove the child, but she has afterwards taken an opportunity to destroy it. Such cases are commonly distinguished from deliberate child-murder by there being no motive, no attempt at concealment, nor any denial of the crime on detection. There is in general a full consciousness of the illegality of the act, but apparently an entire want of power to control the murderous feeling.

Women in the *pregnant* state have been known to perpetrate murder apparently from some sudden perversion of their moral feelings: there has been probably latent intellectual disturbance, but not sufficient to attract the notice of friends. There is a great sympathy between the uterine organs and the brain, which may account for the occurrence of such cases; but I am not aware that irresponsibility on the ground of insanity, unless there were independent proofs of this condition, has been admitted in this country. It would be most unsafe to act on such a principle. On the occurrence of pregnancy, monomania, lypemania, or melancholia, and other disordered and capricious states of mind may show themselves in women predisposed to attacks of this kind; but it cannot be admitted that the pregnant state produces *per se* a disposition to rob, steal, or murder. A case has been communicated to me, in which an intelligent woman, *æt.* 29, who was advanced in pregnancy, felt a strong desire to murder her three children, to whom she was fondly attached. She informed her husband and her medical attendant of this feeling, which haunted her in spite of every effort to shake it off. She was sent away from the children. Such feelings, when they cannot be controlled, and the current of thought changed, indicate the existence of incipient mania. There can be no doubt that, as a rule, a pregnant woman possesses a free will just as in the ordinary condition, and that

she is as fully conscious of her actions. M. Stolz affirms that since this doctrine of responsibility in reference to pregnant women has been made known by medical men, there has been a cessation of criminal acts on the part of these women. (“Ann. d’Hyg.,” 1873, 2, p. 149.)

Pyromania. Propensity to incendiarism.—This is described as a variety of monomania in which there is a morbid disposition of mind leading to impulsive acts of incendiarism without any motive. It is a condition not specially recognized by English jurists, or in English courts of justice.

Kleptomania. Propensity to thieving.—This term has been applied by Marc to that form of monomania which is said to manifest itself by a propensity to acts of theft. It is alleged by him and others that this propensity has often shown itself in women laboring under disordered menstruation, or among those who are far advanced in pregnancy—the motive being the mere wish of possession. Pregnancy, according to him, should be a good exculpatory plea, when a well-educated woman, of strictly moral conduct, steals some unimportant article, of no value to herself compared with her worldly means and position in society. There are several instances on record showing that well-educated persons, moving in a respectable sphere of society, have been guilty of petty acts of theft. The articles taken have been valueless compared with their means. Instances of this kind have been brought before our police courts, and this motiveless impulse to theft has been occasionally pleaded; but in most of them the following facts have been clearly established by evidence: 1. A perfect consciousness of the act and of its illegality. 2. The article, though of trifling value, has still been of some use to the person,—thus, women have stolen articles either adapted to female use, or on which money could be raised. 3. There have been art and precaution in endeavoring to conceal the theft; and, 4, either a denial of the act when detected, or some evasive excuse. When circumstances of this kind are proved, either the persons charged with stealing should be made responsible, or theft should be openly tolerated. The evidence of a disordered state of mind should not be allowed to depend on the nature of the act, or every morally depraved person might bring forward a plea of insanity for any crime or offence. In a trial which took place at the Middlesex Sessions, in August, 1878, a man was charged with stealing a portmanteau from a railway station. In his defence, the prisoner said that he was a kleptomaniac; but the plea did not avail him. He was sentenced to imprisonment and hard labor. This case shows that Marc’s suggestion has reached the class of common thieves. When the facts proved really justify a plea of insanity in a case of stealing, the rule appears to be (per Tindale, C. J.), there should be proof that the prisoner was incompetent to know that the particular act in question was a wrong one. (*Reg. v. Vaughan*, Monmouth Sum. Ass., 1844.) When there is satisfactory evidence on this point, the person will be acquitted on the ground of insanity, and detained during her Majesty’s pleasure. This is shown by the following case, which was tried at the Middlesex Sessions, February, 1875: A clergyman named *Hall*, well educated, was charged with stealing two pairs of ladies’ gloves. The prisoner entered a glove shop in the evening, and asked to look at some dress gloves. He was shown a box,

but expressed a wish for a darker color. While the shopwoman turned for the purpose of getting them, he took three pairs from the drawer, and had concealed them in his pocket. He at first denied that he had them; offered to pay for them, and tried to leave, but was detained. When before the magistrate, he said he was liable to attacks on the brain, at which times he did not know what he was doing.

Dr. Tuke was called for the defence. He deposed that some years before, he had on two occasions attended the prisoner for disease of the brain. He was a man of high attainments. He had recently seen him, and found him suffering from brain-disease, so that at times he was quite mad. He believed that the prisoner did not know the nature or quality of the act he committed at the time of its commission, and that his opinion of the mental state of the prisoner was not affected by hearing the evidence for the prosecution. The jury found a verdict of not guilty, on the ground of insanity; and he was ordered to be detained during her Majesty's pleasure. Although the prisoner had shown in the act the usual cunning of thieves in stealing behind the back of the vendor, in trying to conceal the theft, denying it, and trying to escape, the evidence was very conclusive in showing that he labored under mania. The articles stolen were not such as he could use or wear, and of only the paltry value of a few shillings.

Erotomania. Aidoiomania.—Erotomania has been described by M. Esquirol as a chronic affection of the brain leading to mental disorders in which amorous ideas are as predominant and as uncontrollable as religious ideas in some cases of religious melancholia. It occurs in both sexes, and in his opinion it differs from nymphomania and satyriasis in the fact that it has its origin in a primary disturbance of the functions of the brain from disease. In nymphomania, however, the female sexual organs, and in satyriasis the male sexual organs are at fault. These two mental conditions he regards as depending on morbid changes in the sexual organs. Dr. Marc has suggested that the term *aidoiomania* (from *αἰδοῖον*, pudendum) is more appropriate; it signifies *furor genitalis*, and includes both nymphomania and satyriasis. ("De la Folie," vol. 2, p. 182.)

It cannot be denied that, from sympathy between the genital organs and the brain, mania may sometimes show itself by excessive sexual desire leading to attempts by one on the other sex. This is the very difficulty to the admission of such a defence. Excessive amorous propensities may exist in sane and responsible persons, and if unresisted by due moral control, they may in a certain sense be described as irresistible; but this will hardly satisfy a court of law that a man could not help perpetrating a rape when time and circumstances were especially favorable for such an assault on a woman. The sane ravisher will generally seek his opportunity,—the maniac will attack any woman openly and indiscriminately. Such a defence is rarely set up in a case of rape, for the reason, no doubt, that all the circumstances of the case would be adverse to it.

Dipsomania. Drunkenness.—*Civil responsibility of drunkards.*—This state, which is called in law frenzy or "*dementia affectata*," is re-

garded as a temporary form of insanity. Jurists and legislators have differed widely respecting the degree in which drunkards should be made responsible for their acts. When the mind of a man is completely weakened by *habitual* drunkenness, the law infers irresponsibility, unless it plainly appears that the person was at the time of the act, whether of a civil or of a criminal nature, endowed with full consciousness and reason to know its good or evil tendency. Any *deed* or *agreement* made by a person when drunk is not invalidated by our law, except in a case in which the intoxication has proceeded so far as to deprive him of all consciousness of what he is doing; and a court of equity will not interfere in any case, unless the drunkenness is proved to have been the result of collusion by others for the purposes of fraud. When the drunkenness has occasioned a temporary loss of the reasoning powers, the person is incapable of giving valid consent, and therefore cannot enter into a contract or agreement; for this implies *aggregatio mentium*, *i. e.*, a mutual assent of the parties. Partial drunkenness, therefore, provided the person knew what he was about, does not vitiate a contract or agreement into which he may have entered. Thus the law appears to define two states in drunkenness:—one in which it has proceeded to but a slight extent, and it is considered that there is still a power of rational consent; another in which it has proceeded so far that the person has no consciousness of the transaction, and therefore can give no rational consent. The proof of the existence of this last state would render all the civil acts of a person void. (See p. 829, *ante*.) A confession made by a man while in a state of drunkenness is legally admissible as evidence against him and others, provided it be corroborated by circumstances. In a case tried a few years since, the prisoner confessed, while drunk, that he had committed a robbery and murder which had taken place some time before, but of which he had not been suspected. He mentioned a spot where the property of the murdered person had been concealed by him, and the whole of the circumstances of the murder. The property was found as he had described it, and the case was clearly brought home to him, chiefly by collateral evidence from his own confession. He was convicted. In a case tried at the Central Criminal Court, in October, 1849, a man pleaded his drunkenness at the time of his first marriage as a defence to a charge of bigamy. There was some evidence to show that he was partly intoxicated when the ceremony was performed; it was proved, however, that he was sufficiently conscious of the whole of the proceedings, and he was convicted. (“*Med. Gaz.*,” vol. 44, p. 762.)

Criminal responsibility of drunkards.—When *homicide* is committed by a man in a state of *drunkenness*, this is held to be no excuse for the crime. If voluntarily induced, whatever may be its degree, it is not admitted as a ground of irresponsibility, even although the person might not have contemplated the crime when sober. (*Reg. v. Reeves*, Derby Winter Assizes, 1844.) Thus it appears that when the state of drunkenness is such that any civil act would be void, a person may still be held legally responsible for a crime like murder. Some judges have admitted a plea of exculpation when the crime has been committed in a state of frenzy arising from *habitual drunkenness*; but even this is not

general. The question whether the person was or not at the time of committing the crime may be, however, of great importance. It was held by Paterson, J., that there is no excuse for any crime whatever, yet it is of great importance in cases in which there is a question of *intention*. A person drunk as to be utterly unable to form any intention may be guilty of very great violence. (*Reg. v. Pritchard*, 1846.) If the drunkenness has produced a disease then a criminal act perpetrated by the person, in relation either on the ground of insanity or of the drunkenness at the time of the act; but the difficulty is the existence of actual disease in a sufficient degree to render the person irresponsible in a legal sense. When it is a question whether the act was actuated by malice or not, a jury may under certain circumstances be required to take the fact of drunkenness into account. This may have some influence upon their verdict. Drunkenness does not furnish any excuse for a crime, it is only with reference to the *intent* with which a crime is committed. ("Law Times," Sept. 27, 1845, p. 542.) It is a question whether drunkenness were to be readily admitted as a defence in crimes committed in this country would go unpunished.

In cases in which the head has sustained any physical injury, soldiers and sailors, drunkenness, even when existing at the time of the crime, produces sometimes a fit of temporary insanity, but when the drunken fit is over. The law makes no distinction between state and ordinary drunkenness, although juries often return verdicts that some difference ought to be made. (*Reg. v. Pritchard*, p. 653.)

Hallucinations and illusions are a common effect of drunkenness, and may lead to the commission of criminal acts. Many cases have been recorded in which two friends being intoxicated, the one killed the other, and it was held that he was an evil spirit. The drunkenness of the person who committed the crime has been voluntary; and he was condemned to death with hard labor. A case of this description (*Reg. v. Pritchard*) was tried at the Norfolk Lent Assizes, 1840. A man was charged with the murder of his friend, who was also intoxicated, under the illusion of another person who had come to attack him. It is a question whether the prisoner was made to react upon the fact, and when sober, he would have perpetrated the act under the same illusion. He had voluntarily brought himself into a state of intoxication: no justification: he was found guilty of manslaughter and sentenced to two months' imprisonment.

The proof of drunkenness may fail, but still the act may be proved. If the death acted under an illusion, he will be found guilty. *Price* (Maidstone Summer Assizes, 1846), a prisoner, who had been on friendly terms with the deceased, at night, having previously been in company with him at a public house. According to the prisoner's statement, he was from the hedge by the roadside, and demanded his life, or else he said he would have his life: the prisoner

beat him severely, inflicting such injuries that he died shortly afterwards. The supposed robber turned out to be his friend, and it was believed that he had made an attempt to rob the prisoner jokingly: the result, however, was that the attempt had ended in this fatal manner. The prisoner throughout told the same story, and there did not appear to be the slightest ground for suggesting that it was untrue. Coltman, J., after hearing the evidence of the witness, said it appeared to be quite clear that the prisoner had acted under an impression that he was protecting his own life from the attack of a robber, and under such circumstances he could not be held to be criminally responsible. The jury accordingly returned a verdict of *not guilty*, and the prisoner was discharged.

An excessive indulgence in habits of drinking does not necessarily derange the mind, but it may practically render a person unfit for the control of himself and the management of his property. It is therefore a question whether it would not be for the benefit of such persons and of those dependent on them, if the law interfered and placed them under the same restraint as those whose minds had been actually rendered unsound by this pernicious habit. (See "Lancet," July, 1875, p. 135.) [The law does so interfere in Pennsylvania—p. 818 *ante*.—P.]

Delirium Tremens.—This is a disordered state of mind which proceeds from an abuse of intoxicating liquors. Habitual drunkenness appears to be the predisposing, while abstinence from drink is the immediately exciting, cause. Thus, the disorder frequently does not show itself until the accustomed stimulus has been withdrawn for a certain period. It commences with tremors of the hands, by which it is known from ordinary delirium and restlessness; and the individual is subject to hallucinations and illusions, sometimes of a horrible kind, referring to past occupations or events. The patients are often violent, and prone to commit suicide or murder—more commonly the former; hence they require close watching. Persons proved to be laboring under this disorder are incompetent to the performance of any civil act; and they are not responsible for criminal acts, committed while they are suffering from an attack. Acquittals have even taken place on charges of murder, when there was deliberation as well as an apparent motive for the act. Thus then, although this disorder may have been voluntarily brought on by habitual drunkenness, the law admits it as a sufficient plea for irresponsibility, while in a case of confirmed drunkenness it rejects the plea. In delirium there is a formed disease of the brain, while voluntary drunkenness merely produces a temporary disturbance of its functions. In one trial the evidence showed that homicide had been committed by the accused while he was laboring under an attack of delirium tremens. (*Reg. v. Simpson*, Appleby Summer Assizes, 1845.) The prisoner's mind had become unsettled from this disorder, brought on by habitual drunkenness. In another case the plea was also admitted by the jury, although it was scarcely supported by the medical evidence. (*Reg. v. Watson*, York Winter Assizes, 1845.) In a case tried at Liverpool Assizes (*Reg. v. Burns*, Aug. 1865), a man laboring under delirium tremens was charged with the murder of his wife. After the act, he appeared calm, and said that he knew perfectly well what he had done; "his wife was in league with men who were hidden in the walls." Baron Bramwell in charging

the jury said, "there were two kinds of insanity by reason of which a prisoner was entitled to be acquitted; probably the jury would not be of opinion that the prisoner knew not the quality of his act—that it would kill, and was wrong; but it was still open to them to acquit him if they were of opinion that he was suffering from a delusion leading him to suppose that which, if true, would have justified him in the act. One more more remark he would make—viz, that drunkenness was no excuse, and that a prisoner cannot by drinking qualify himself for the perpetration of crime; but if through drink his mind had become substantially impaired, a ground of acquittal would then fairly arise." The prisoner was acquitted. In *Reg. v. Chaplin* (Warwick Ass., Nov. 1878), prisoner was charged with felonious wounding, by firing a revolver at two persons. It was proved that at the time of the acts, the prisoner was suffering from an acute attack of *delirium tremens*, brought on by sudden cessation from excessively hard drinking. Medical evidence also proved that at the time, and for two days after, he was in such a state that he would not know the nature of his acts. He fired the shots under the delusion that some one was breaking into the house. Upon this evidence the prisoner was found not guilty, on the ground of insanity. In another case (*Reg. v. M'Gowan*, Manchester Assizes, Oct. 1878), it was proved that the prisoner, who was charged with the murder of his wife, had been drinking for two or three weeks. The medical evidence was to the effect that he was suffering from temporary disease of the brain as a result of excessive drinking—that the man knew what he had done, as he had voluntarily given himself up for it, but that he was not accountable for his actions. Manisty, J., said if a man's insanity was so fixed, habitual, and permanent that it reduced him to a state of being without reason or mind, then he was not accountable or responsible for his actions. But if the prisoner's insanity was only temporary and produced by his own excesses, the law did not excuse him from the results of his acts. The prisoner was found guilty.

As in one of the cases above noticed, an attack of *delirium tremens* may be brought on by the sudden withdrawal of alcoholic stimulants from a person long accustomed to take them in excess. The sudden abstinence from other narcotics, such as opium and hydrate of chloral, may induce a similar attack. A person might thus be rendered temporarily unconscious of his actions, and therefore legally irresponsible for an act of violence committed while he was in this state. A case has lately occurred in Canada in which this question arose in reference to the hydrate of chloral. There is reason to believe that this drug would operate on the brain and nervous system in the same manner as alcohol, opium, and morphia. ("Guy's Hospital Gazette," Jan. 1879, p. 9.)

[Many of the States of the Union have statutes defining murder, and dividing it into degrees. Where this is the case, the existence of intoxication and its effect upon the mind of one charged with homicide becomes of much importance, upon the question of intent and premeditation. The "American Law Journal," for October, 1848 (p. 145), contains the following admirable article upon this subject:—

"The medical *status* produced by drunkenness is frequently determined by the testimony of physicians. But the effect of that state of

mind, voluntarily produced, in relieving from responsibility for crime, is to be determined by the courts. Sir William Blackstone quotes the language of Sir Edward Coke, who declares that ‘a drunkard who is *voluntarius dæmon* hath no privilege thereby; but what hurt or ill soever he doth, his drunkenness doth aggravate it.’ And Sir William adds, that ‘the common law of England, considering how easy it is to counterfeit this excuse, and how weak an excuse it is, though real, will not suffer any man thus to privilege one crime by another.’ (Plow. 19, 4 Bl. 26, 1 Inst. 247.) The effect of this severe rule of the common law is frequently to fix upon the accused the legal guilt of a crime of much greater enormity than he ever intended to commit. But the great value of the common law is that it is founded upon far reaching views of policy, which look beyond the justice of the particular case, for the purpose of protecting the higher interests of society. It seems to be conceded as a principle of the common law that a man who willingly perpetrates an unlawful act is responsible for all its consequences. Hence, a man who accidentally kills another by discharging a gun at a sheep, or a domestic fowl, for the purpose of stealing it, is guilty of murder at common law, although his mind never in fact assented to the enormity of taking the life of a fellow being. On the same principle, it would seem that a man who voluntarily puts himself in a state of mind which causes him to take the life of another is guilty, by construction, of the common law crime of murder.

“The hardship of this rule has sometimes caused the scales of justice to vibrate in its application to capital cases. In 1819, Mr. Justice Holroyd, in *Rex v. Grindley*, under the influence of his feelings, held that, ‘though voluntary drunkenness cannot excuse from the commission of crime, yet where, as upon a charge of murder, the material question is whether the act was premeditated, or done only with a sudden heat and impulse, the fact of the party being intoxicated is a circumstance proper to be taken into consideration.’ (Lewis’s Crim. L. 602; 1 Spear’s, 384.) This decision has doubtless had its influence elsewhere. The error of Mr. Justice Holroyd consisted in supposing that at *common law* it was always ‘a material question’ in murder ‘whether the act was *premeditated*’ or not. We have seen that *premeditated* killing was not always essential to constitute the crime; otherwise it never could have been held murder to kill a human being accidentally in the premeditated perpetration of larceny. There is some reason to believe that subsequent reflection brought the mind of that enlightened judge to an acknowledgment of his error. In 1835, in the case of *Rex v. Carroll*, Mr. Justice Parke, after citing the case of *Rex v. Grindley*, decided by Mr. Justice Holroyd, remarked that, ‘highly as I respect that late excellent judge, I differ from him, and my brother Littledale agrees with me. He once acted upon that case, but afterwards retracted his opinion, and there is no doubt that case is not law. I think that there would be no safety for human life if it were to be considered as law.’ (7 Car. and Payne, 145; 32 Eng. Com. Law, 471; Lewis’s Crim. Law, 602, note.)

“Mr. Justice Story, in the *United States v. Drew*, took a distinction on the effect of intoxication which, on account of its humanity, has received general commendation. That learned judge held that insanity, of

which the remote cause is habitual drunkenness, is an excuse for an act done by the party while so insane, *but not at the time under the influence of liquor*. The crime (to be punishable) must take place during a fit of intoxication, and be the immediate result of it, and not a remote consequence superinduced by the antecedent drunkenness of the party. In cases, therefore, of *delirium tremens* or *mania à potu*, the insanity excuses the act, *if the party be not intoxicated when it is committed*. (5 Mason, 28; Am. Jurist, vol. 3, p. 5 to 30; *Burnet v. The State*, Martin & Yerger, 133; *Cornwell v. The State*, ib. 147; Lewis's Criminal Law, 602, note.)

"In Virginia, where there is a statute dividing murder into degrees, like that of Pennsylvania, it is believed that a similar view of the law prevails. (*Com. v. Jones*, 1 Leigh, 612.)

"In Tennessee, Mr. Justice Reese, in 1843, in delivering the opinion of the Supreme Court upon a similar statute, has explained the law on this interesting question in language so clear and forcible as neither to be misunderstood nor refuted. In the case of *Swan v. The State*, 4 Humphreys, 136, the judge makes the following remarks:—

"The characteristic quality of murder of the first degree, and that which distinguishes it from murder in the second degree or any other homicide, is the existence, at the time of the death of the assaulted, of a settled purpose and a fixed deliberate design on the part of the assailant that his assault should produce death. The length of time which the assailant deliberates on his intention is not material. Drunkenness is no excuse for or justification of crime. But although drunkenness in point of law constitutes no excuse or justification for crime, still, when the nature and essence of a crime is made by law to depend upon the peculiar state and condition of the criminal's mind at the time, and with reference to the act done, drunkenness as a matter of fact affecting such state and condition of the mind, is a proper subject for consideration and inquiry by the jury. The question in such a case is, what is the mental *status*? Is it one of self-possession, favorable to the formation of a fixed purpose by deliberation or premeditation? or did the act spring from existing passion, excited by inadequate provocation, acting it may be on a peculiar temperament, or upon one already excited by ardent spirits? In such case it matters not that the provocation was inadequate, or the spirits voluntarily drank. The question is, did the act proceed from sudden passion, or from deliberation and premeditation? To regard the fact of intoxication as meriting consideration in such a case, is not to be held that drunkenness will excuse crime, but to inquire whether the very crime which the law defines and punishes has in fact been committed. If the mental state required by law to constitute the crime be one of deliberation and premeditation, and drunkenness or other cause excludes the existence of such mental state, then the crime is not excused by drunkenness, or such other cause, but has not in fact been committed."

Of course it is not to be understood from the foregoing article that drunkenness is any defence to the *factum* of guilt. It is only with reference to the question of intent, and with the view to reduce the *degree* of guilt from murder in the first degree, which in most of the States is punishable with death, to murder of the second degree or to manslaughter.

ter, the punishment of which is only imprisonment more or less extended, that evidence of intoxication is receivable. *Commonwealth v. Kilpatrick*, 7 Casey, 203; *Com. v. Miller*, 17 Legal Intel. 276 (Ludlow, J.).

Nor will it be sufficient even for this purpose, unless the intoxication be so great as to render the prisoner unable to form a wilful, deliberate, and premeditated design to kill, or incapable of judging of his acts and their legitimate consequences. (*Keenan v. Commonwealth*, 8 Wright, 55; *Com. v. Miller, Ib. v. Kilpatrick*, supra.)—P.]

Somnambulism.—This term strictly applies to sleep-walking, but the medico-legal facts are chiefly confined to acts of violence perpetrated unconsciously, or in a state of “unconscious cerebration” during sleep, in which it is presumed that malice and intention, the chief ingredients of crime, are wanting. It has been a contested question among medical jurists, how far a person should be held responsible for an act perpetrated in that half-conscious state which exists when he is suddenly aroused from sleep. There is no doubt that the mind is at this time subject to hallucinations and illusions, which may be more active and persistent in some persons than in others; but it is difficult to suppose, unless we imagine there is a sudden access of insanity, that a person should not recover from the delusion before he could perpetrate an act like murder. A remarkable case of this description, that of *Bernard Schedmaizig*, will be found reported by Marc. (Op. cit., vol 1, p. 56.) This man suddenly awoke at midnight, and saw, as he believed, a frightful phantom. He twice called out, “Who is that?” and receiving no answer, and imagining that the phantom was advancing upon him, he seized a hatchet which was beside him, attacked the supposed spectre, and it was found that he had murdered his wife. He was charged with the murder, but pronounced “not guilty,” on the ground that he was not at the time conscious of his actions. A trial involving this question occurred in England. A peddler in the habit of walking about the country armed with a sword-stick, while lying asleep on the high-road, was roused by a man accidentally passing, who seized and shook him by the shoulders. The peddler suddenly awoke, drew his sword and stabbed the man, who soon afterwards died. The peddler was tried for manslaughter. His irresponsibility was strongly urged by his counsel, on the ground that he could not have been conscious of an act thus perpetrated while in a half-waking state: and this defence was supported by the opinion of a medical witness. The prisoner was, however, found guilty. Under such circumstances, it was not unlikely that an idea had arisen in the prisoner’s mind that he had been attacked by robbers, and therefore had stabbed the man in self-defence. (*Rex v. Milligan*, Lincoln Autumn Assizes, 1836.) In July, 1878, one *Simon Fraser* was tried in Scotland for the murder of his child. It was proved that he lifted the child from its bed, and killed it by dashing its head against the wall of the room. The defence was that it was done unconsciously, while he was in a state of somnambulism. He dreamed that he had seen a wild beast jump into his bed, and he rose to attack it. It seems that from boyhood he had been accustomed to get up in his sleep. The Lord Justice Clerk directed the jury to find that the prisoner “had killed his child when unconscious of the act, by reason of his condition as a somnambulist, and that he was not respon-

sible for his actions." ("Brit. Med. Jour.," July, 1878, p. 108.) In *Reg. v. Byron* (Winchester Winter Assizes, 1863), it was proved that a blow struck by a drunken person during sleep had caused death. The man was charged with manslaughter, under the following circumstances: The prisoner and deceased were soldiers in the same regiment, at Aldershot. The prisoner was in the street drunk, and deceased seeing this took him in, to prevent his being arrested for drunkenness, and placed him on his bed. In this state he lay for some time quite drunk and insensible. In the course of the afternoon deceased went upstairs to see him; he tried to awaken him, when the prisoner suddenly kicked out, and his boot came violently against the lower part of the abdomen of the deceased. The prisoner did not awake, but appeared then to be quite insensible. The deceased died, and it was found that the blow had caused rupture of the intestines. As, in order to constitute the crime of manslaughter, it must be shown that the person charged did something knowingly, and the prisoner was not in a state to have known anything, it was held that there was no case against him, and he was acquitted. The act was committed during sleep, but the sleep appears to have been the result of voluntary drunkenness.

Somnambulism may become a subject of discussion under a contested policy of life-insurance, in which it may be provided that it shall be vitiated by suicide. If a man falls from a height and is killed while in a state of somnambulism, would this be considered an act of suicide within the meaning of the policy? The proviso against suicide has been held to include only *intentional* killing (case of *Borradaile v. Hunter*, "Med. Gaz.," vol. 36, p. 826), and in death under these circumstances, the killing cannot be said to be intentional; it can be regarded only as an accident—therefore it is reasonable to infer that the policy would not be void. It is impossible, however, to lay down any general rules relative to cases of this description; since the circumstances attending each case will sufficiently explain how far the act of murder or suicide has been committed during a state of somnambulism, or under an illusion continuing from a state of sleep.

Responsibility under the new Code.—The new Criminal Code lays down certain propositions regarding responsibility which may materially affect medical evidence in future cases. Thus it is provided that no act shall be an offence if the person who does it is, at the time when it is done, prevented either by defective mental power or by any diseases affecting his mind—

- (a) From knowing the nature of his act;
- (b) From knowing either that the act is forbidden by law or that it is morally wrong; or,
- (c) If such person was at the time when the act was done, by reason of any such cause as aforesaid, in such a state that he would not have been prevented from doing that act by knowing that if he did do it the greatest punishment permitted by law for such an offence would be instantly inflicted upon him; provided that this provision shall not apply to any person in whom such a state of mind has been produced by his own default.

An act may be an offence, although the mind of the person who does it is affected by disease, or is deficient in power, if such disease or deficiency does not, in fact, produce one or other of the effects above mentioned in reference to that act.

This last provision clearly shows that it is not sufficient to prove insanity, but that it has reached a certain degree, in order to justify legal irresponsibility.

Voluntary drunkenness is excepted from the above provisions. They are intended to apply only to involuntary drunkenness and to any disease affecting the mind caused by voluntary drunkenness. (See Dr. Orange's "Relation of Insanity to the Criminal Law of England," 1877, p. 7.)

THE DEAF AND DUMB.

It was formerly laid down in the old law-books, that a person born deaf and dumb was by presumption of law an idiot, but in modern practice, want of speech and hearing does not imply want of capacity either in the understanding or memory, but only a difficulty in the means of communicating knowledge; and when it can be shown that such a person has understanding, which many in this condition reveal by signs, he may be tried, and suffer judgment and execution. (Archbold.) A deaf and dumb person is not incompetent to give evidence, unless he is also blind; he may be examined through the medium of a sworn interpreter who understands his signs. The condition does not justify restraint or interdiction, unless there is at the same time mental deficiency. A deaf-and-dumb person who has never been instructed, is altogether irresponsible for any action, civil or criminal. Such a person cannot even be called on to plead to a charge, when there is reason to suppose that he cannot understand the nature of the proceedings. A deaf-and-dumb woman was charged with cutting off the head of her child. By signs she pleaded "not guilty," but she could not be made to understand the nature of the other proceedings against her. Upon this she was discharged, and subsequently confined as a criminal lunatic. In *Reg. v. Goodman* (Stafford Summer Assizes, 1841), a deaf-and-dumb man was convicted of theft, and sentenced to imprisonment. He was made to comprehend the proceedings by signs and talking with the fingers. In *Reg. v. Brook* (Buckingham Summer Assizes, 1842) the prisoner could read and write well. He was charged with feloniously cutting and stabbing. The proceedings were reported to him in writing. He was convicted, and the judge (Alderson, B.), having sentenced him to a year's imprisonment, handed down his judgment in writing, which he recommended him to read and ponder over in prison! In *Reg. v. Jackson* (Bedford Summer Assizes, 1844), Alderson, B., held that before the evidence of a dumb witness can be received, the court must be satisfied that he understands the obligation of an oath.

It has been decided in the ecclesiastical courts that the consent of a deaf-and-dumb person given by signs, renders a matrimonial contract valid, provided the person has a full and proper understanding of their meaning. An incompetency to enter into contracts or unsoundness of

mind, must not be inferred to exist merely in consequence of a person being deaf and dumb. In the case of *Harrod v. Harrod* (Vice-Chancellor's Court, June, 1854), an attempt was made to deprive the plaintiff of his rights on the ground that he was an illegitimate child. The marriage of his parents took place thirty years previously, but the marriage was said to be void by reason of the alleged incapacity of his mother to enter into the contract; the mother was deaf and dumb, and of more than ordinarily dull intellect. Sir W. P. Wood said there was an important difference between "unsoundness of mind," and "dulness of intellect." The presumption in such cases was always in favor of sanity, and the fact of a person being deaf and dumb did not raise a presumption the other way. Experience in asylums showed that the deaf and dumb were not necessarily of unsound mind. The woman had assented to the marriage in form and substance, and with a perfect knowledge of what she was doing. In the ceremony of marriage it had never been held that the repetition of the words was necessary. The woman conducted herself with great propriety before and after the marriage, and a child was born in due course. There was no ground for an issue.

Feigned deafness and dumbness.—From these statements it will be perceived that medical evidence is of but little importance in relation to the deaf and dumb. Indeed there are only two cases in which this kind of evidence is likely to be called for—1st, when there is accompanying *mental deficiency*, in which case the general rules elsewhere given are applicable; and 2ndly, when there is a suspicion that the deafness and dumbness are *feigned*. There will be no great difficulty in detecting an imposition of this kind. It may be found that the alleged deafness and dumbness did not come on until a motive existed, and that there was no apparent cause, but the very suspicious one of evading responsibility for some offence committed. The use of ether or chloroform-vapor may be occasionally resorted to with advantage for the detection of such an imposition. In one instance a strong shock of the induced current from a large magneto-electrical apparatus, by means of moistened conductors applied over the larynx, brought out after a few minutes the power of speech in a lad who had successfully imposed on many persons. ("Med. Times and Gaz.," March 30, 1861, p. 330.) It requires great skill to maintain an imposture of this kind. Such persons are immediately thrown off their guard by addressing them in a voice a little above or a little below the common conversational tone; a change in the eye or the features will at once indicate that they hear and understand what is said. An ignorant impostor may be dealt with on the principle of "*ars est celare artem*," by seriously proposing in a low voice to a medical friend who may be present, the necessity for the performance of some formidable surgical operation. The production of amputating instruments has been known to have a wonderful effect!

In *Reg. v. Yaquierdo* (Herts Summer Assizes, 1854) the prisoner, who was charged with wilful murder, was found by the jury to be wilfully mute. The man refused to plead, although it was obvious that he was well aware of the nature of the proceedings. No counsel could be assigned to him, as this could not be done without the prisoner's consent. He was convicted and sentenced. Shortly after the trial this man was

found to be insane. He was sent to Bethlehem and was subsequently removed to Broadmoor. Dr. Orange has informed me that he is hopelessly insane, but not mute.

If the impostor can write, he may perhaps be detected by the ingenious plan adopted by the Abt  Sicard. When the deaf and dumb are taught to write, they are taught by the eye. The letters are only known to them by their form, and their value in any word can be understood only by their exact relative position with respect to each other. A half-educated impostor will spell his words or divide them incorrectly; and the errors in spelling will always have reference to sound—thereby indicating that his knowledge has been acquired through the *ear*, and not alone through the eye. A man, who had defied all other means of detection, wrote down several sentences, in which the misspelling was obviously due to errors produced by the *sound* of the words, thereby showing that he must have heard them pronounced. The Abb  concluded that the man was an impostor without seeing him, and he subsequently confessed the imposition.

library by any person or
department.

life or death—all these circumstances have been stated by Prof. Greenleaf as material. There must also be evidence, that learned author proceeds to say, of diligent inquiry at the place of the person's last residence in this country, and among his relatives, and any others who would have probably heard from him, if living; and also at the place of his fixed foreign residence, if he was known to have any. In *Loring v. Steinman*, 1 Met. (Mass.) R. 204, Shaw, C. J., in giving the judgment of the court, says: "It is a well settled rule, that upon a person's leaving his usual home and place of residence for temporary purposes of business or pleasure, and not being heard of, or known to be living, for the term of seven years, the presumption of life then ceases, and that of his death arises. The presumption is greatly strengthened when the departure of an individual was from his native place, the seat of his ancestors, and the home of his brothers and sisters, and family connections; and still further when it was to enter upon the perilous employment of a seafaring life."

Upon this subject, see also Best on Presump. 59-61; *Whiteside's Ap.*, 114 Harris. 114; *Campbell v. Read*, 12 Ib. 498; *Holmes v. Johnson*, 6 Wright, 159; *Windship v. Connor*, 42 N. H. 341.

When the person whose life is in question has gone to sea, the presumption of death may arise much sooner than seven years. Thus in *Patterson v. Black*, Park on Ins. 433-34 (2 Am. Ed.) the question was whether the assured died before the 30th January, 1778. It appeared that about the 20th November, 1777, he sailed from the Cape of Good Hope, in the sloop of war *Swallow*, which ship, not being afterwards heard of, was supposed to have been lost in a storm off the Western Islands. The plaintiff proved the departure, and also called several captains who sailed at the same time who swore that the vessel must have been as forward in her course as they were on the 13th or 14th of January, the period of a most violent storm, in which she was probably lost; and that the *Swallow* was much smaller than their vessels, which with difficulty weathered the storm. Lord Mansfield, who tried the cause, left it to the jury to say whether, under all the circumstances, they thought the evidence sufficient to convince them that the assured died before the time limited; adding, that if they thought it so doubtful as not to be able to form an opinion, the defendants should have their verdict. They found for the plaintiff.

The rule is stated to be that where a vessel is missing and no intelligence of her has been received within a reasonable time after she sailed, it is presumed she foundered at sea. Thus, where a ship was insured in 1739, from North Carolina to London, an action was brought against the underwriters. The only evidence was that she had sailed on her intended voyage, and had never since been heard from. The defendant objected that as captures and seizures were excepted by the policy, it lay in the assured to prove a loss by sinking, etc. The Chief Justice (Lee), however, said that it would be unreasonable to expect evidence of that, for as everybody on board was presumed to be drowned, the plaintiff had given the best proof the nature of the case admitted of. The case being left to the jury, they found for the plaintiff. (*Green v. Brown*, 2 Strange, 1199.)

In order to raise this presumption, however, it must be distinctly shown that the ship left the port, bound on her intended voyage; and although her not being heard of for many months or years raises a presumption of her crew having perished, it affords none as to the precise *time* of the death of any person on board. This must be collected by the jury from the circumstances of the case. (*Watson v. King*, 1 Stark R. 121; *Sillick v. Booth*, 1 Y. & C. N. C. 117; Best on Presump. 145-6.)

Where two or more persons perish by the same calamity, the question sometimes arises, when the circumstances of their deaths are unknown, which one is presumed to be the survivor. By the Roman law, if it were the case of father and son, where the latter was under the age of puberty, he was presumed to have died first; but if above that age, the presumption was the other way. By the French code, if the persons perishing are under the age of fifteen, the eldest is presumed to have survived; if above the age of sixty, the youngest. If between those ages, and of different sexes, the male is presumed to have survived; if of the same sex, the presumption is in favor of the younger. (Greenleaf's Ev., vol. 1, § 29.)

But in the common law, no rule on the subject has been laid down; and the better opinion is that the presumption is that all perished together. (Ib. § 30.) However, in the case of *Moehling v. Mitchell*, 1 Barb. Ch. (N. Y.) 264, where a married woman procured an insurance on the life of her husband, for her own use, the money to be paid to her, unless she died before him, and in that case to her child, pursuant to the act of 1840 (2 R. S., 3 ed. 207, §§ 60, 61), and sailed with her husband and child in a ship which was never heard of again; *held*, there being no presumption that the child survived her, or that she survived her husband, that the case did not fall within the act, and that the insurance money was part of the personal estate of the husband.

"If any circumstances of the death of either party can be proved, there can be no inconvenience in submitting the question to a jury, to whose province it properly belongs." (1 Greenl. Ev. § 30.) Thus in the case cited by Blackstone, from Cro. Eliz. 503 (2 Black. Com. 132), upon the question of what constituted a sufficient seisin on the part of the husband to entitle the wife to dower, where a father and son were both hanged in one cart, but the son was supposed to have survived the father by appearing to struggle longest; the jury found that he was the survivor, whereby he became seized of an estate in fee by survivorship, in consequence of which seisin his wife had a verdict for her dower. (See also upon this subject, Best on Presump. 190-202.)—P.]

Different rules have been given by actuaries for calculating the expectation or duration of life at different ages. It is difficult to test their accuracy, except in reference to large numbers of persons living under similar circumstances, and for these groups of the population statistics do not fairly provide. Age is the point from which nearly all the Tables of Mortality start, without reference to health, trade, occupation, or social position. One of the most simple of these rules for calculating the duration of life from 5 to 60 years has been given by Willich; he considers

it to be equal to two-thirds of the difference between the age and 80. Thus, in a man 20 years of age the difference is equal to 60, and two-thirds of this are equal to 40, the probable duration of life for a person of average health at 20. Each office has its own rules for calculating the amount of premium to be paid by the person who effects an insurance. As insurance offices are very numerous and their profits are large, it is obvious that their calculations must be very much in their own favor. The expectation of life in the insured is ordinarily much greater than they assign to it; at the same time, the amount payable in the form of premium is kept down by competition.

With respect to the influence of *profession*, a higher premium is demanded by some offices for the insurance of the lives of persons whose occupations expose them to great risk—as, for instance, of persons actually engaged in military or naval service. The rule adopted with respect to professions in one of the best London offices is as follows: “No extra premium is required from any person in the army or navy, unless on actual service, but the assurance will be void if the party whose life is assured enter into any naval or military service whatever, unless by consent of the directors, endorsed on the policy.”

Above all other conditions, *the general state of health* of the person is likely to have a most important influence on the mean duration of life; and it is here that medical science lends its aid—1st, by showing how far a contract may be safely entered into when the person is affected with disease; and, 2dly, by showing whether a diseased state of the body really existed in the person insured, although at the time of insurance it may have been alleged that he was healthy and free from disease.

By improved methods of diagnosis, the existence of disease under a proper examination is easily made known, or it may be at once inferred from symptoms described by non-professional persons. Then, again, the influence of particular diseases in shortening life are now so much better understood than formerly, that the numerous offices have of late years been especially established for the insurance of *diseased*, as well as of healthy lives, the amount of premium being of course regulated by the nature of the disease, and the degree to which it may have advanced. In these cases, lives are insured as if the persons had reached a greater age, the amount paid being calculated on the theory that the person is ten, fifteen, or twenty years older than he is.

As in the case of all civil contracts, the law requires that there should be a strict compliance with the conditions by each party, it follows that, if any fraud has been committed by the insured—if he, or those to whom he trusted in his dealings with the office, have concealed from the insurers the existence of any disease under which he was at the time laboring, or any symptoms indicative of a probable attack of disease; or if he or they have knowingly and wilfully misrepresented or misdescribed his actual bodily condition, then the contract will be void, and the amount of the premiums forfeited. This forfeiture is a usual condition in the policy. Actions on policies of life insurance are not unfrequent; and, unfortunately, the medical evidence given on these occasions, as in cases of insanity, is of a very conflicting character. This is by no means creditable

to the profession, for it either proves the existence of great bias in the witnesses, or that medical rules are devoid of all certainty, and are therefore practically useless. A writer, in commenting upon these professional conflicts, says: "One of the most unsatisfactory parts of our law of evidence is that which relates to the testimony of experts. It is impossible to shut out such evidence altogether, but there is nothing which brings more discredit upon the administration of justice. There is one consequence of its admission which is common to all cases in which it occurs. It is, that no difficulty has ever been found in obtaining any amount of evidence of this description on either side of any point at issue." It will be, therefore, necessary to enter into an examination of the circumstances under which medical men are called upon to appear. An action is never likely to be brought for the recovery of the amount of a policy, except in those cases where there is reason to suspect that a wilful fraud has existed in the contract. Juries always regard such actions with disfavor; and while judges interpret the law strictly, the onus of proof is entirely thrown upon the offices. Hence the insured are placed in a very advantageous position. These actions, in nine cases out of ten, depend upon the construction put on the medical terms of the contract; hence, it is our duty to see how medical defects are likely to arise in reference to the policy. The conditions of insurance vary in different offices.

[Statements in an application for life insurance, "upon the faith of which the policy is expressed to be made, with a stipulation that if they shall be found in any respect untrue, the policy shall be void," are warranties, and if untrue, even in a point immaterial to the risk, avoid the policy. *Miles v. Connecticut Mutual Co.*, 3 Gray (Mass.) 580; *Cazenave v. Ins. Co.*, 6 C. B. (N. S.) 437.—P.]

No one can blame insurance offices for acting rigorously. Frauds of the worst description have been frequently attempted upon them, and it is only by the adoption of a system of this kind that they can protect themselves.

The chapter on life-insurance in the first edition of this work has been translated by M. Tardieu with numerous additions. ("Ann. d'Hyg.," 1866, 1, 383, and 2, pp. 120 and 382.) Among them he gives copies of the questions to which answers are required by many French, German, and Spanish offices. They do not materially differ from those usually asked, but the more recent offices have evidently profited in this respect, by the experience of the older institutions in Great Britain. Dr. Gmelin, of Stuttgart, has collected the formularies of questions put by fifteen different offices, chiefly German, to the medical attendant of the intending insurer. He finds that they vary from a minimum of ten to a maximum of thirty-two questions. He divides them into superfluous, indiscreet, irrelevant, and misleading. (Eulenberg, "Vierteljahrs.," 1872, 1, 271.) From the minuteness of some of these inquiries it appears that a much more difficult duty is thrown upon German than upon English medical practitioners. According to M. Tardieu, some French companies act upon a much more reasonable plan, and leave the medical attendant perfectly free to draw up a certificate according to his own views. ("Ann. d'Hyg.," loc. cit.)

The relations of medical men with insurance officers.—Medical responsibility.—The practice with some offices in obtaining a certificate gratuitously from the medical attendant of the person proposing to insure his life is one great source of litigation. The responsibility of causing the life to be accepted or rejected is thus thrown entirely upon the usual medical attendant of the person; for, as we shall see hereafter, an application for a certificate from a medical practitioner who is a stranger, is very likely to be treated as a fraud, and to lead to the disputing of the policy. The medical attendant of the person, it is true, is the only individual who can properly certify to the real state of health, and therefore to him an application is generally made. He is sometimes expected to furnish an important certificate of this kind gratuitously; and should it happen to be unfavorable, he is exposed to the risk of losing what may probably be a lucrative portion of his practice: for I shall not suppose that any member of the profession would certify to what he knew to be untrue, in order to retain a patient. The question is, whether an insurance office has a right to place a medical man in such a responsible position as this. In the issuing of a policy, the insurers and insured are equally benefited, for the contract would certainly not be made except upon a supposition of reciprocal benefit. The medical attendant, without whose sanction the policy could not be properly effected, not only derives no benefit, but is actually exposed to the risk of loss for performing in an honorable and conscientious manner an invidious duty thus forced upon him. Such a state of things ought not to be. Many actions for the recovery of disputed policies have shown most clearly that the practice leads to great carelessness and indifference on the part of medical men in drawing up these certificates; and this produces, in the end, a more serious loss to the representatives of the insured, than if the life had not been accepted. It must be remembered that the insurers do not suffer by any misconduct on the part of a medical man who signs such a certificate, but the representatives of the insured; hence, the offices show no disposition to amend this vicious system. It is always professed that such communications are confidential; but in more than one instance medical men have found that the contents of their certificates have become known to their patients, and have even been publicly used as evidence in courts of law. A partial remedy would be, that the medical attendant of this party should not be called upon to sign a certificate at all, but that this should be done only by a medical referee of the office, after a regular professional consultation with the medical attendant, and a proper examination of the person. If the life were rejected, the onus of rejection would be on the proper person—the appointed referee; and if accepted, he would be properly made responsible to the office for any gross negligence in the performance of his duties. It is true that there are few insurance offices which have not consulting physicians and surgeons attached to them; but the weight of responsibility in contested suits does not rest with these officers so much as with the medical attendants of the insured. In the event of a medical practitioner being called upon to sign a certificate of this kind, it appears to me that the safe plan to be adopted would be that he should decline the proposal, except upon a professional consultation with the medical officers appointed by the insurers. If, how.

ever, from private considerations, he is compelled to sign the certificate, it is his duty to use the greatest caution, not merely in returning answers to the formal questions on the paper, but in detailing *all particulars known to him respecting the state of health of the person*. In acting otherwise, he would be doing the greatest possible injury to the representatives of the insured, and probably damage his own reputation. There is no intermediate course; the duty must either be performed carefully, conscientiously, and honorably, or it must be declined altogether. [The practice of sending blank certificates to be filled up by the regular medical attendant of the applicant, gratuitously, has become as great a nuisance in the United States as in Great Britain. We are clearly of the opinion that it is not the physician's *duty* to comply with such requests; it is optional with him to do it, or not. In the first place, the company has no right to the service without an adequate compensation; and secondly, there may be cases in which the family physician would have serious doubts as to the propriety of divulging professional secrets connected with his patient's former health, *e. g.*, in the case of syphilis; or of certain habits, as of occasional drunkenness or opium eating. Of course, all such points must be known to the applicant himself, and on him alone must devolve the risk of any concealment.—R.]

Diseases tending to shorten life.—Let us take the case, however, that this preliminary duty has been properly performed: important medical questions may arise respecting the alleged infringement of the conditions of the policy. The list of diseases specified comprises a great variety—affections of the head, apoplexy, palsy, epileptic or other fits, disease of the brain, insanity, disease of the lungs, spitting of blood, asthma, inflammation, disease of the heart, dropsy, diseases of the bowels, liver, kidneys, or urinary organs, gout, rheumatism, hernia, phthisis, or any hereditary disease. In the proposals of some offices, the mysterious word “fits” occupies a very prominent position, but it is difficult to say what this word thus isolated actually means. It appears to have been borrowed from the vocabulary of the ancient searchers under the bills of mortality in the reign of Charles II. Thus it may comprise, apoplexy, epilepsy, paralysis, syncope, convulsions from any cause, and even asphyxia. The word is too indefinite for a certificate, and should be expunged. In the mean time, a court of law will not allow insurers to benefit by the use of ambiguous terms in the contract, and it has therefore commonly restricted the meaning of the word “fits,” to attacks of epilepsy. The main condition, however, is involved in the terms—“*any other disease or disorder tending to shorten life.*” Upon the meaning of these words litigation commonly turns, and the opinions of medical experts are required.

It is impossible to lay down any general rules for determining what diseases have, and what diseases have not a tendency to shorten life. Any deviation from health might be so interpreted; but the law puts a proper limitation here upon the meaning of the words, considering them to apply to those diseases only which, in a medical view, are regarded as of a serious nature, and, as a general rule, are likely either directly or indirectly to affect the duration of life of any person laboring under them. This question was brought to an issue in the case of *Watson v. Mainwaring*,

in which payment of the amount of a policy was refused, because the insured had labored at the time under what was called *organic dyspepsia*; and this fact was kept concealed from the insurers. It was left as a question of fact to the jury, whether the malady with which the deceased was afflicted, and of which he ultimately died, was an ordinary or organic dyspepsia at the time of the insurance. The judge (Chambre) in charging the jury said: "All disorders have more or less a tendency to shorten life, even the most trifling; as, for instance, corns may end in mortification; but that is not the meaning of the clause. If dyspepsia were a disorder tending to shorten life within this exception, the lives of half the members of the profession of the law would be uninsurable." We learn then, from this case, that a person may die from a disease under which he was laboring at the time of insurance; and yet if it be not the common course of the disease to shorten life, the representatives may recover the amount of the policy. This is an equitable interpretation of the terms; for the insurers have no right to give a forced meaning to the words of the policy, and to take advantage of what must be regarded as an accidental result. From other decisions we learn that, in order to render a policy valid, these words do not imply that the insured must have been at the time entirely free from all the seeds of disorder or latent disease. Such a condition is impossible. A man may be laboring under some insidious disease—ulceration of the stomach or intestines, for instance—leading to perforation; but if this be, as it commonly is, unknown both to himself and his medical attendant, the insurers are bound to take the risk. Lord Mansfield in the case of *Sir James Ross*, held that the warranty was sufficiently true, if the person were at the time in a reasonably good state of health. A life may be a good life, although the person may be at the time laboring under some bodily infirmity.

[The assured, who effected a policy on his life in February, 1855, signed a declaration stating, among other things, that he was then in good health, and did ordinarily enjoy good health; and that he was not aware of any disorder or circumstance tending to shorten his life, or to render an insurance on his life more than usually hazardous, unless anything stated in answer to certain questions which preceded the declaration might be so considered. In an action upon the policy, it appeared that in 1853 and 1854, the deceased had had two severe bilious attacks. Medical men had expressed different opinions as to the effects of these attacks upon his health; but it did not appear that the unfavorable opinions had ever been communicated to the assured. It was held that it was proper to instruct the jury that, "if the assured honestly believed at the time he made the declaration, that the bilious attacks had no effect upon his health, and did not tend to shorten his life, or render an insurance upon it more hazardous, the fact that he was aware that he had had these attacks, even though (without his knowledge) they had such a tendency, would not defeat the policy." *Jones v. Provincial Ins. Co.*, 3 C. B. (N. S.) 65.—P.]

[In the case of *Emilie Moulor v. Am. Life Ins. Co.*, to recover \$10,000, the sum insured on the life of her husband, Louis Moulor, of New Orleans, the defence rested mainly on the allegation that the de-

ceased had returned false answers to the questions regarding his health. It was however proved that his representations were perfectly true to the best of his knowledge and belief: although the defence endeavored to show by the affidavit of his family physician (a homœopathist), that he had actually been afflicted with several grave disorders—asthma, consumption and scrofula—of which, however, he (the physician), averred the patient was perfectly ignorant, as he had never deemed it prudent to inform him! But, as the deceased had never suffered from any of the *symptoms* of these diseases, he could hardly be expected, under the circumstances, to be aware of their alleged existence, and consequently the plaintiff pressed the suit. The case was tried several times before the U. S. Circuit Court, in Philadelphia, 1873–77, a verdict being finally rendered for the defendants. An appeal was then taken to the U. S. Supreme Court; but the final decision has not yet been reached.—R.]

On the other hand, a disease tending to shorten life must not be taken to signify only one of those maladies which have commonly a rapid and fatal course—as phthisis and scirrhus; it may apply to dropsy, gout, asthma, insanity, and many diseases of a chronic character. When the existence of these diseases, or even a well-marked *tendency* to them, is concealed from the insurers, or omitted to be stated through mistake, even without fraudulent intention, the policy in the event of death becomes void, because the risk incurred is really different from the risk understood and intended at the time of the agreement. Such diseases are not necessarily fatal, but this is not the question; their *tendency* is to diminish the expectation of life, and if medical evidence establish this with regard to any disorder intentionally concealed, whether chronic or acute, the contract is at an end.

Gout.—In December, 1862, a case was tried in which it was alleged that there had been concealment of the existence of gout. (*Excrs. of Fowkes v. The Manchester and London Assurance Company.*) The deceased, Fowkes, a commercial traveller, aged 49, in the year 1860, effected a policy on his life for 1000*l.* He died in June, 1861. Payment was refused on the ground that the answers of deceased were untrue, and that there had been suppression of a material fact. It seems he was asked whether he had ever been *afflicted with gout*, and he answered “No.” He was asked whether the life had been offered at any other office, and, if so, whether it was accepted; and he answered that it had been proposed, and had been accepted at the ordinary rate. These were the answers which it was alleged were false. On the part of the company, a surgeon stated that in May, 1858, deceased was suffering from suppressed gout. He had an “extremely slight attack,” which lasted only about forty-eight hours; he did not tell the deceased that it was gout; he believed that he died of suppressed gout in an aggravated form. A proposal of the deceased to another company, which had been declined, was put in evidence. On the part of the plaintiffs it was contended that there was no evidence that deceased had ever been “afflicted with gout.” The Lord Chief Justice left it to the jury—first, whether the answers of the insured were untrue; and next, whether they were false to his knowledge. First, had he been “afflicted with gout?” The question must be considered with some reasonable latitude, and it

was not because a person had some passing symptoms which a far-seeing medical man might ascribe to the presence of suppressed gout in the system, but whether there was gout in a sensible appreciable form? This certainly was stated before the proposal, to have been "the slightest possible case" of gout, according to the medical evidence. As to the other question—whether the life had been proposed at any office and accepted or declined—it appeared that the life had been proposed at two offices, and accepted by one, but declined by the other. Had the assured answered truly in simply saying that he had been proposed and been accepted? The question no doubt was not in the most comprehensive form, but was it answered fully and fairly, and according to its obvious meaning and effect, by saying nothing of the proposal which had been declined? He thought not; but left it to the jury. He, however, thought further that it was not strictly true that the life had been "accepted" in the sense in which the word was used—for it had not been accepted by any office on a proposal for an assurance, but merely approved by the medical man. It was for the jury to say whether either of the answers was untrue, and, if so, whether either was untrue to the knowledge of the assured. The jury found that the assured had not been afflicted with gout at the time of the proposal; also, that the answer to the other question was untrue, but not to his knowledge. The Lord Chief Justice directed a verdict for the plaintiff, subject to a point reserved for the court, whether the knowledge of the untruth was material.

Habits.—Again, a person may be laboring under no actual disease at the time of affecting the insurance, but his *habits* may be such as to produce general injury to health, and to have a tendency to shorten life. Concealment of habits, the effect of which on health must, or ought to be known to all medical men, may be just as fatal to a policy as the concealment of a serious disease. Although they may not always be included in the questions put by the office, yet the law will equitably hold that the insurers should be made acquainted with all circumstances which might reasonably affect the risk. Concealed habits of drunkenness have thus given rise to medical questions of considerable importance; and in one remarkable instance which will be mentioned hereafter, a question arose as to whether the habit of opium-eating, which had been concealed from the insurers, had or had not a tendency to shorten life.

Some recent exposures, partly of a civil, and partly of a criminal nature, have rendered insurance offices much more strict in their inquiries. In the rules already quoted, special information is demanded upon the existence of material circumstances touching health or habits of life, and whether the person is, or is not of temperate habits. Any facts bearing upon these questions, if known to the medical attendant, must of course be stated. The existence of such habits must be known to the person himself, and the declaration which he signs is so explicit that, if intentionally concealed by him, no individual can reasonably complain of the avoidance of the policy and the forfeiture of the premiums.

The case of *Von Lindenau v. Desborough*, tried in the Court of King's Bench before Lord Tenterden in October, 1828, shows that medical men are bound, at the risk of invalidating the policy, to state the exact

bodily condition, so far as it can be obtained by observation, of the person whose life it is proposed to insure. It appears that on the 16th of June, 1824, a policy for 3208*l.* was effected, in the Atlas office, on the life of the Duke of Saxe Gotha, at the time he was residing abroad. The Duke died on the 17th of February, 1825, within nine months of the time of effecting the insurance; and the payment of the amount of the policy was refused on account of a material concealment of the exact condition of the insured from the insurers. It appeared in evidence that for some time prior to the insurance, the Duke had been an invalid, and that at the time it was effected he was childish, and had not spoken for two years. He had labored under some affection of the brain, did not improve in health after the insurance, and ultimately died from an attack of paralysis. The certificate upon which the insurance was granted had been signed by two German physicians, Drs. Dorl and Ziegler. It was to the effect that the general health of the Duke was good; but that he was "hindered" (*gehindert*, had an impediment) in his speech, and had an affection in his left eye. It was also stated that he was perfectly free from disease, or symptoms of disease. On inspection of the head, a tumor of large size connected with the inner table of the skull was found pressing upon the brain. This tumor was evidently of long standing, and had probably been the cause of the symptoms and death. Ten ounces of serum were found effused in the brain.

It appears that before the insurance was effected, an agent in Germany had informed the insurers that the Duke had led a dissolute life, by which he had lost the use of his speech, and, according to some, of his mental faculties also; and on this the office required a payment of nearly double the usual premium. The case of the insurers was that there had been material concealment of the Duke's real condition at the time of effecting the insurance. The late Mr. J. H. Green, who appeared as a witness for the plaintiff, the claimant under the policy, considered, from the history of the case, that there were no symptoms of organic disease, although the symptoms mentioned would lead to a suspicion of disease in the head. In reply to a question by Lord Tenterden, he said if, as a medical man, he had been asked by an insurance company concerning the state of a man's health, who was unwilling to move, who was subject to control and influence, and who had lost his speech, he would have considered it his duty to mention these circumstances. Lord Tenterden then left it to the jury whether there had been any concealment of material facts relative to the Duke's health. The plaintiff was nonsuited, and a new trial subsequently refused.

There can be no doubt that the answer here given by Mr. Green was such as every conscientious man must have given under the circumstances. A medical expert appears in court to speak the *whole truth*, to the best of his judgment, and not to make out rightly or wrongly the particular case of the person who summons him. On the other hand, it is obvious that Drs. Dorl and Ziegler gave a most improper certificate. They might not have been able to express any opinion respecting the existence of a tumor in the brain, but they were wrong in suppressing the real state of the Duke. If they knew his actual condition, their conduct was censur-

able ; if they did not know it, they were not justified in signing a certificate at all. Because a man may enjoy at the time tolerable bodily health, facts of this nature, showing great disease of the nervous system, ought not to be kept from the knowledge of the insurers. Imbecility, depending on whatever cause, should always be mentioned.

Material concealment.—Some medical practitioners entertain the opinion that, provided they can certify that the person is in good health at or about the time of the insurance, that is all that the insurers need know. The same opinion is commonly entertained by the insured ; and the latter, after having been attended by one medical man for an illness, will apply to another, a comparative stranger, to certify to his condition of health for insurance. We must not lend ourselves to this system, which is based sometimes upon a mistake, at others upon fraud. If medical men would decline signing the papers under such circumstances, they would not only save themselves from censure, but be actually conferring a benefit upon the applicant, by preventing him from obtaining a policy upon terms which on his death may render it invalid, and entail a forfeiture of the premiums. From what has already been said, it will be understood that the exact state of health of the person at the time of the insurance does not represent the whole of the risk incurred by the office. The restoration to health, as in a case of diseased lungs, may be only temporary ; it may be speedily followed by phthisis, and the insurers therefore ought to be informed of the previous condition, as well as present state of the applicant. The conditions in the declarations are so explicit upon this point, as to render it scarcely necessary to refer to the propriety of making this addition to the certificate. The disease under which the insured had labored may have been of a trivial kind, and not likely to affect the risk. When facts of this kind are either concealed, or not plainly stated, the question of how far they were or were not material to be laid before the insurers is always left to the jury, who are guided in their verdict by their own common-sense, as well as by medical opinions. It would appear, also, from a decision of the House of Lords in *Anderson v. Fitzgerald*, that the truth of the answers given, and not their materiality, should govern the verdict of a jury. In a case tried in December, 1856, Lord Campbell held that a suppression of the truth on the part of the person whose life was insured, would not avoid the policy, if the party effecting the insurance was innocent and ignorant of the suppression.

Some medical men have adopted the plan of signing certificates, but have declined to make any written reply to certain queries : as, for instance, the general query—Can you give any, and what information respecting the *habits* of the applicant ? If nothing be known concerning these, it should be so stated ; if, however, the existence of any habits affecting health be known to us, we shall do an injury to the applicant and ourselves by withholding information on the subject. It may be the means of causing a heavier premium to be demanded for insurance than if the facts were known ; and if this should not happen, the omission is very likely to give rise to future litigation. Thus, in the case of the *Earl of Mar*, the payment of the policy was refused on the ground that

the Earl had been addicted to opium-eating. His medical referee replied favorably to the *special* questions in regard to habits, whether sedentary or active, temperate or intemperate; but he neglected to reply to the *general* question regarding habits; and on the Earl's death it was found that he had been an opium-eater for many years before effecting the insurance. This fact might not have been known to the medical referee, but it is always better to fill in the reply either affirmatively or negatively, if the certificate be signed at all, than to leave the office to draw an unfavorable inference, or to render the policy afterwards open to dispute.

In the case of a *Mrs. Elgie* payment of the amount of a policy was refused under the following circumstances: The insured had been for some time prior to the insurance in a delicate state of health, and in the year 1821 it was thought that the symptoms were those of *phthisis*. In October, 1822, she was twice alarmingly ill. In December of that year, wishing to insure her life, she called in a medical friend, who had not been in attendance upon her, to examine her and certify as to her state of health. It appears he examined particularly the state of her lungs and liver, and finding them as he thought, sound, certified that the ordinary state of her health was good. On the 19th March, 1823, he gave another certificate to the same effect, upon which the insurance was effected in April, 1823. Mrs. Elgie died of disease of the lungs in April, 1824. Payment was refused, on the ground that there had been concealment of the material facts as to the state of health of the insured. It appears that, unknown to the medical gentleman who had given the certificate, the insured had been attended between December, 1822, and the 19th March, 1823 (the date of the certificate), by a medical practitioner residing in her neighborhood for a cough, and that she had become much emaciated. This gentleman, however, thought there was no structural disease—an opinion confirmed by the examination made for the certificate in March. The fact of the deceased having labored under this illness was, however, concealed from the insurers. The jury thought that, although there had been concealment, it was not material, and a verdict was returned against the defendants. A new trial was granted, but a verdict was again returned against them. The truth is, it is not the concealment of every slight attack of illness that will vitiate a policy; although the contract being one, as it is termed, *uberrimæ fidei*, it is in the highest degree unwise either in the insured, or, if it be known to him, in the medical man signing the certificate, to conceal from the insurers any previous illness or medical attendance from another quarter. It may always be fairly urged that a knowledge of the facts might have led to the rejection of the life, or have made a difference in the amount of the annual premiums. One part of our duty, therefore, if we sign a certificate upon a careful examination, is to ascertain whether the applicant has, or has not been previously attended by another medical practitioner.

A case was tried at the Warwick Summer Assizes, 1844 (*Geach v. Ingall*), in which it was alleged that the existence of *phthisis* (pulmonary consumption), or phthisical symptoms, had been concealed from the office. On the side of the plaintiff, the medical attendant of the insured was called, and he certified that in May, 1840, when the policy was

thought that the hernia was quite recent. The operator found no adhesions, and there was nothing to induce him to suppose that the hernia was of fourteen months' standing. Evidence was also given to show that the witness who deposed to the existence of inguinal hernia before the insurance might have been mistaken in his diagnosis, and have confounded a hydrocele or a varicocele with a hernia; but admitting this to be true, the existence of a tumor of any kind in such a situation should not have been kept concealed from the company or their medical referee. The jury returned a verdict that there was no fraud, but that the deceased had had hernia at the time of effecting the insurance. A second trial was granted, and a verdict was then returned in favor of the plaintiffs.

If, under any circumstances, a jury should find that the concealment is material, the legal consequence is that the policy is void. It is not at all necessary that the person should die of the disease concealed. This rule was laid down by the late Lord Tenterden in the case of a *Colonel Lyon*. The colonel insured his life by two policies in May and June, 1823, and died of a bilious remittent fever in October of that year. Payment was refused on the ground of misrepresentation and concealment. Colonel Lyon referred the office for a certificate of his health to a gentleman who had not attended him for three years previously. His answers to the printed questions were that he had had no other medical attendant, and that he never had "a serious illness." The medical gentleman to whom he referred certified that his life was insurable, and the policy was issued. It appeared in evidence, however, that the deceased had been attended by two other medical practitioners from February to April, 1823, for hepatitis, fever, and a determination of blood to the head. One of these employed very active treatment; he considered him to be in a dangerous state, and would not have certified him to be in health until the end of May, 1823. All agreed that the deceased did not die of the disease for which he had been thus attended. Lord Tenterden stated it to be his opinion, that if a man referred to one practitioner because he could speak well of his health, and thought that if he referred to other medical men they would not so certify, although the insured did not die of the disease with which he was then afflicted, the policy would be void. A verdict was accordingly given for the defendants. The practice of referring to medical men who have been only recently consulted is not infrequent. The opinion of the usual medical attendant might be unfavorable, or he might report on the existence of habits which would render the life uninsurable, or insurable only at a high premium. This want of fair-dealing, however, commonly defeats its object. There is expensive litigation, and the policy is pronounced to be void. The case of *Wilshere v. Brown*, tried before Lord Abinger in the Exchequer in December, 1842, and of *Palmer and Fish v. Irving*, tried at the Norwich Summer Assizes, furnish illustrations of this. In the latter case the deceased had returned that he had never had a medical attendant. His life was insured for a large sum on the 21st November, 1842, and he died on the 5th December following. There was reason to believe that he had died from inflammation of the lungs; but it was proved that he had labored under symptoms of pulmo-

nary consumption, and had been attended by three medical men shortly before he effected the insurance. This was concealed, and the policy was set aside on the ground of fraud.

A singular case was tried at Glasgow in 1837, in which the proceedings were inverted, compared with the usual English practice in such cases. An insurance company brought an action against the representatives of the insured, on the issue whether the policy had not been obtained by misrepresentation and undue concealment. An insurance was effected on the life of a *Mrs. Ralston*, on the 10th December, 1833. Her own declaration was that she was in good health, and that she was not afflicted with any disease or disorder tending to shorten life. She referred to her usual medical attendant, who certified that he had known her for ten years, and had been in the habit of attending her professionally; that she was last ill in the month of September, 1833; "that her indisposition was acidity of the stomach;" that she had not, to his knowledge, been affected with any illness of such a nature as to influence her general health; that she was then (30th Nov. 1833) in perfect health, and was not subject to fits or any affection of the head, but occasionally to slight headache from acidity in the stomach. He knew of no circumstance in her business or habits of living tending to impair her health or shorten her life. The deceased died of apoplexy on the 3d September, 1834, within nine months from the issuing of the policy. The insurance company were about to pay the amount, when an action was brought by the medical attendant against the executors of the deceased for payment of 162*l.* for medical attendance, etc., on *Mrs. Ralston*, from the 15th September, 1833 (two months prior to the date of the policy) to the 4th June, 1834. The referees awarded 145*l.* to the plaintiff. His books were given in evidence, and it then appeared that between the 19th September and 3d December, 1833 (the date of the proposal for insurance), he had paid her thirty-five professional visits, most of these of long duration. It further appeared from the diary that she had been frequently bled; her head had been shaved and blistered, and leeches had been applied to her temples. She had also had constant attendance after the insurance, and in the early part of 1834 had had several fits of epilepsy. Three medical witnesses deposed that the declaration of deceased and the certificates given by her medical attendant did not set forth her true condition; and that there had been misrepresentation and concealment of material facts. This was also the opinion of the judge, and a verdict was returned for the office. Although the illness prior to the insurance might have had no connection with the death from apoplexy, it was held that the insurers ought to have been made acquainted with it.

Among the diseases upon the concealment of which policies have been most frequently disputed, may be enumerated, gout, dropsy, paralysis, epilepsy, hæmoptysis, incipient phthisis, delirium tremens; and to this list may be added drunkenness, intemperance, irregular habits, prostatic disease, and laceration of the perineum in women, as a consequence of delivery.

Intemperate habits.—In a large number of cases the payment of policies is resisted on the ground of concealed drunkenness and general

habits of intemperance. There is some difficulty in these cases, because medical men may entertain different opinions respecting the effect of such habits upon the general health, and the degree to which they may be safely carried. There is one thing, however, certain—whatever may be our opinion of their effect on health, we are bound to state, if known to us, that they exist, and thus put it out of the power of a company to dispute a policy upon such a ground. From the frequent concealment of habits of this kind, some offices now adopt the practice of making it a special question, to which a plain negative or affirmative answer should always be given: “Are you now, and have you always been of temperate habits of life?”

When intemperance is alleged, we find not only conflicting medical evidence, but much cross-swearing among the witnesses. It becomes a question: What is intemperance? and this is answered according to the peculiar views of a witness. A case was tried at the Exeter Spring Assizes in 1842 (*Southcomb v. Merriman*), which will show the difficulty of getting at the truth. Payment of a policy was disputed by the office on the ground of concealed intemperate habits. At the trial the representatives of the insured called twelve witnesses to prove that the deceased was a very temperate man, while the office called twenty-one to show that he was habitually intemperate! One of the temperance witnesses (for the plaintiff) defined drunkenness to be “when a man has lost his reason, could not give a proper answer, was not able to do business, had lost his legs, and was obliged to be carried home.” He admitted that the deceased had occasionally continued drinking for three or four days together, but that was a very rare occurrence. The medical attendant who gave the certificate said that the deceased’s was a perfectly good life, and he considered him to be a person of sober and temperate habits: he had not thought it requisite to inform the office of occasional outbreaks, because he did not think that drinking had any effect upon his health. Several witnesses proved that deceased was in the habit of drinking enormous quantities of beer, and that it required a great deal to make him ramble. The insurance was effected in October, 1839, and the deceased died in April, 1841, from inflammation of the lungs; but, in the opinion of the medical witnesses, this had not arisen from excessive drinking. Notwithstanding the concealment of these facts, the jury returned a verdict for the full amount claimed; but a rule for a new trial was afterwards obtained. This case shows what fallacious views are entertained on the medical questions of life-insurance. In a case like this, it was clearly the duty of a medical man to describe the habits of the deceased. He might, if he pleased, have appended to the certificate that in his judgment they had not affected the health of the person, but the defendants who were to take the risk should have been placed in a position to form a judgment for themselves.

In the case of the Hon. H. G. Talbot (*Craig v. Fenn*, December, 1841), where no answer was returned to the question whether the deceased was of temperate and moderate habits of life, and the company actually charged a higher premium in consequence, the jury returned a verdict in their favor, the real condition of the insured not having been made known to them at the time the insurance was effected.

[Where the representation was made that the insured was of sober and temperate habits and in good health; if the representation was true at the time it was made, the subsequent habits of the insured would be no bar to a recovery upon the policy. (*Reichard v. Manhattan Life Insurance Company*, 31 Missouri R. 515.) And if the party insuring is not called upon by any general or special question, he need make no statement as to any particular habit, as intemperance, though such habit may be prejudicial to his health. *Rawls v. Life Ins. Co.*, 36 Barb. (N. Y.) 357. Where the insurance is by a creditor upon the life of his debtor, declarations of the latter as to his habits, or as to the fact of suppression of information are mere hearsay, and inadmissible as evidence. *Ib.*—P.]

Concealed habits of intemperance.—In *Hutton v. Waterloo Life Association* (Q. B. December, 1859), an action was brought by a widow for the recovery of 2500*l.* upon a policy effected in April, 1854, on the life of her husband. Payment was refused on the ground that the written answers made by deceased to questions proposed by the company were false, and therefore that the contract which was based upon them was void. One question was whether he was subject to *delirium tremens* or any disease calculated to shorten life, which he answered in the negative; a second was, whether he was of temperate and sober habits, which he answered in the affirmative; and the third was as to the name and residence of his "ordinary medical attendant, to be referred to as to present and general state of health," to which he answered, "Dr. Cobb." The inquiry now was whether these answers were true. The action had already been once tried, when the plaintiff obtained a verdict; but the court granted a new trial upon the ground that there was no finding by the jury.

The evidence in the case, medical and general, showed that the deceased was of intemperate habits, and that in May, 1854, he had suffered from *delirium tremens*, of which disease he died in 1856; further, that Dr. Cobb, to whom he referred as his usual medical attendant, had not attended him since 1851, and that from this date until the date of the insurance he had been attended by another medical man, to whom he had given no reference, although he was his usual medical attendant. The jury found for the defendants on the main issues. This case presented two curious features: 1st, the medical evidence proved that the first attack of *delirium tremens* came on on May 11, after the insurance had been effected; and 2dly, the medical attendant of the deceased and the medical officer of the company differed greatly about the deceased's state of health at or about the time the insurance was effected. The medical attendant of the deceased, who was a witness for the company, deposed that he attended him for an attack of *delirium tremens* on May 11, and again on May 28, 1854—both attacks being the results of excessive drinking. The report to the company, made by their own medical officer, dated May 22, 1854, gave, however, a most flattering account of deceased's health, and described him as a "first-class life." In his evidence at the trial this gentleman said that he then observed no indication of *delirium tremens* nor of drunken habits; the deceased was the

picture of health. This serious discrepancy could not be reconciled by a re-examination of the witnesses. The concealment of intemperate habits was clearly proved, and on this probably the verdict of the jury chiefly turned.

Questions of a similar kind were raised in *Wheelton v. Hurdisty* (Q. B. Dec. 1856). An insurance had been effected to a large amount on the life of a Mr. Jodrell, and the payment of the policy was disputed on the ground that there had been concealment of intemperate habits, and of the existence of delirium tremens at the time the insurance was effected. The jury found that there had been misrepresentation and concealment.

One of the most singular cases of this description, in reference to conflicting medical evidence, was that of *Rawlings v. Desborough*, tried by Lord Denman in December, 1837. The main question was, whether a Mr. John Cochrane, whose life had been insured, was or was not a person of intemperate habits at, or before the time of insurance. A medical certificate had been given to the effect that his habits were not intemperate. The weight of the evidence, however, general and medical, tended to show that he was a thorough drunkard. One of the witnesses for the plaintiff said, the deceased "never appeared to me to take anything to hurt a man; I never saw him drink more than the rest of the company; I only saw him intoxicated fifty or sixty times in four years! His health did not seem to be impaired by what he drank." His groom stated that he had seen his master "tipsy a hundred times, perhaps, but not beastly drunk." The late Mr. Travers examined the deceased for one office, and from what he saw, he advised that his life should not be accepted. He considered the man to be laboring under *delirium tremens*. One observation made by this witness is worthy of remembrance when a medical practitioner is engaged in examining a person for a life insurance—*i. e.*, a man may have pursued an intemperate course for some time, and yet his appearance at the time may be such as to lead a common observer to imagine he was in the plenitude of health when he is liable to become the subject of an immediate attack. Notwithstanding the strong evidence of habits of intemperance from a period anterior to the date of the insurance, the jury returned a verdict for the plaintiffs, but a motion for a new trial was soon afterwards made. Lord Denman observed upon this occasion, in respect to what was *material concealment*, that he did not conceive the true meaning to be, that the party whose life was to be insured was bound to volunteer a statement of every circumstance that anybody might afterwards think was likely to effect the risk of his life. The real intention was, that he should submit himself to a full examination and inquiry, that he is bound to state nothing untruly, and that he is bound to answer all questions truly. If he decline to answer, the office may act upon his refusal, and if he answer untruly, he shall gain no benefit from such false statement.

In February, 1840, a trial took place before Tindal, C. J. (*Pole v. Rogers*) relative to a policy on the life of Mr. Peter Cochrane, brother of this Mr. John Cochrane. The insurance was effected in 1834. The insured died the following year of *hydrothorax*, brought on, as it was alleged by defendants, by very intemperate habits, the existence of which

was concealed from them. The evidence, both was just as conflicting as in the former case, a question of credibility. The jury returned a verdict thereby either denying the existence of intemperance, the concealment of it, if it existed, was not material.

This case is worthy of note in one point of view, a question in medical jurisprudence—namely, what are the *immediate* or *remote* effects on the body from intemperate habits? The Solicitor-General, who appeared for the representatives of the insured, argued that the test of "to health" were too indefinite. Was it to be an absolute or relative proposition? He appeared to rest his case on the fact that there was intemperance to a certain degree, habits which were not at all prejudicial to the health, but which absolutely kill another. There was a very complete compensation; this might be utterly destructive to the health of one person, but not to that of others. This sort of condition left it open to an insurance office to resist the claim unless the meaning of the words was brought within well-defined limits. The jury were bound to say that if intemperate habits had been indulged in for a long time, they must look to all the habits of the person to see whether one habit was not counteracted in its effect by another. The insured was a man of very active habits, and the intemperance would not affect him as it would others who led a sedentary life.

This ingenious but sophistical reasoning involves a difficult question. It is well known that intemperance in drinking may be differently construed by different medical authorities. The question, however, divested of its sophistry, is whether a man who indulges in an excessive use of alcoholic liquids without any other cause, or later leading to an impairment of health, by the action of the stomach and liver, and remotely affecting the system, the effects of such habits may not show themselves immediately, but requires to be informed of their existence or non-existence at the period when they are likely to affect health by the production of a fatal disease. To assert that a man can be intemperate without impairing his health is contrary to fact. There is no such compensation, or balance of habits, as the Solicitor-General supposed to exist in this case.

A man who indulges in intemperance—it may enable him to drink a large quantity of alcoholic liquid without being apparently injured by it for some time; but a deranged state of system will soon manifest itself, delirium tremens or dropsy will probably supervene, and a robust constitution may enable a man to resist the pernicious effects of intemperance for a long period, but ultimately they will show themselves as a fatal disease; and in the case of these two brothers, the intemperance was made apparent in the very deaths of both. It is a rule that no light is permitted to be thrown on such cases by post-mortem examinations are not always made, and the death being, as it is called, natural, it is not commu-

to inspect the body, although as in the above instances, the condition of the liver and other organs might at once have removed a difficulty which arose from the conflicting evidence on the habits of the deceased.

In all cases of a contested policy, one important principle is uniformly acted upon; those who resist the payment are bound to prove what they allege by conclusive and satisfactory evidence. A court will not receive probability or conjecture—the evidence must be certain. Hence many suits fail from the medical evidence going no further than to show that a particular disease or habit had *probably* existed at the time of insurance. If the disease or habits be shown to have *certainly* existed, the evidence may still fail to prove satisfactorily that the concealment was either wilful or material.

Contested cases of life-insurance are very instructive: they often show the imperfect manner in which medical observations respecting health or disease are made, and that the medical treatment of persons whose lives are insured may become a material question in the event of a policy being disputed. In the case of *Chattock v. Shawe*, in reference to an insurance on the life of a Colonel Greswold, a question arose not only respecting the concealment of intemperate habits, but as to the concealed existence of delirium tremens, from the examination of handwriting, as well as from the description given by non-professional witnesses. It was here even doubtful what had caused the death of deceased. According to one medical witness, it was a curious combination of Asiatic cholera, phrenitis, and epilepsy! It was proved that, more than three years before the insurance was effected, this gentleman had met with a fall, and he was afterwards seized with a fit, described by some witnesses as epileptic, by others as arising from concussion of the brain. The existence of intemperance and epilepsy prior to the insurance was not made out to the satisfaction of the jury, and they returned a verdict for the representatives of the insured.

In *Walters v. Barker*, tried at the Monmouth Summer Assizes, 1844, the deceased, at the age of sixty, insured his life on the 4th May, 1841, and he died in the August following. It was alleged by the office that the cause of death was an attack of *paralysis*, which it was pretended had existed from a very early period of his life. No medical evidence was given on either side; there was merely a presumption that death might have taken place from paralysis; hence the verdict was for the plaintiffs.

Abstinence. The vegetarian system.—We have already considered the effects of habits of intemperance, and the necessity for stating in a certificate the existence of them when known; but other habits may exist which have a tendency to shorten life, although in a less obvious manner. What are called *temperance* principles are, or were very prevalent. There are many persons who have been full livers, and have afterwards taken up the notion that water and a vegetable diet were all that was necessary to support life. This sudden change, especially in persons advanced in life, is very likely to affect the constitution seriously, and, if not to create disease, so to weaken the vital powers as to render any slight illness or accident serious. I knew one instance in which a gentleman who had been in the habit of living on a full diet, with a

moderate use of alcoholic liquids, suddenly adopted the plan of living on water and vegetable food; he obviously fell off in strength, and lost his previously healthy condition. About a year afterwards he met with a slight sprain to the ankle-joint; inflammation ensued, which, in spite of the best treatment, assumed an unhealthy character; suppuration of the joint followed; amputation of the leg was performed, but, in spite of an improved diet, the powers of life never rallied. There was no attempt at union in the flap, and he finally died exhausted. There can be no doubt that these sudden changes in the mode of living are liable to lead to impairment of health, and to affect materially the expectation of life. Hence it is our duty to inquire and report upon facts of this kind, when they become known to us.

In *Huntley v. The St. George Insurance Company* (Newcastle Autumn Assizes, 1858), a medical man insured his life for 2000*l.*; and, although certified to be in good health, and to all appearance he was so, he died from Bright's disease within three months after he had effected the insurance. There was also disease of the heart. The questions whether he had either of these diseases at the time of the insurance were answered by him in the negative. It was contended that, as a medical man, he must have known that he was suffering from these diseases, and had wilfully concealed them. It appeared from the evidence that the deceased had taken to a vegetable diet, and it was considered that this was the cause of the rapid failing of his health. The jury returned a verdict for the plaintiffs, and the Chief Baron suggested that in future, insurance companies should put among their questions to insurers, "Are you a vegetarian?"

Opium-eating.—There is another habit said to be common, the concealment of which gave rise to an important trial some years since: I allude to the practice of *opium-eating*. In 1826, the *Earl of Mar* effected an insurance on his life, and two years afterwards, *i. e.*, in 1828, he died of jaundice and dropsy at the age of fifty-seven. The insurance company declined paying the amount of the policy, on the ground that the Earl was, at the time of the insurance, and had been for some time previously, an opium-eater. This practice was concealed from the insurers; and it was further alleged that it had a tendency to shorten life. It was clearly proved in evidence that the Earl had been a confirmed opium-eater up to the time of his death. According to Dr. Christison, the deceased had taken laudanum for thirty years, at times to the amount of two or three ounces daily—a tablespoonful for a dose. He was a martyr to rheumatism, and, besides, lived rather freely. Many persons who were constantly about him, and many intimate friends, deposed that until 1826 (the year of the insurance) he was of a cheerful disposition, and clear in his intellect. Some of them admitted that they then perceived a change in his habits, which they attributed to the adverse circumstances in which he was compelled to live. In 1825, Dr. Abercrombie found him enfeebled and broken down in constitution, but without any definite complaint. The main question at the trial was, whether opium-eating had a tendency to shorten life—for on this the

issue turned—whether the concealment from, or the non-communication of this practice to the office, was or was not material.

Drs. Christison, Alison, Abercrombie, and Duncan were examined on the part of the insurers; and although they entertained the opinion that the habit had a tendency to shorten life, they were unable to adduce any cases in support of it. Their opinion was based not on personal experience, but on the general effects of opium as manifested by its action on the brain—by its producing disorder of the digestive organs, and giving to the person a worn and emaciated appearance. In most of the instances collected, there was no evidence that life had been shortened by the practice. On the contrary, some of the individuals had carried it on for years, and had attained a good old age. The jury returned a verdict for the plaintiffs, not on the ground that the practice was innoxious and its concealment immaterial, so much as on the technical point that the insurers had not made the usual and careful inquiries into the habits of the deceased; and they were therefore considered as having taken upon themselves the risk from their own *laches*. It appears that the general question with respect to habits was not answered by the medical referee, and it was, therefore, considered that the office had waived the knowledge of them. A new trial was granted, on the ground of misdirection, but the suit was compromised.

Hence it will be seen that no decision was come to in this case on an important question, which is very likely to arise again. It will be desirable, therefore, to examine some of the facts connected with opium-eating, in order, if possible, to see how far it really tends to shorten life. In the case of the Earl of Mar, it appeared to be a fair inference that the habit did not shorten his life, for he is represented to have indulged in it for thirty years; and for twenty-eight years, according to the statements of his friends, no injurious effects had followed. Dr. Christison subsequently collected from numerous sources no fewer than twenty-five cases, from which we learn that opium has been taken in large quantities for forty years together, without producing any marked injury to health. At the London Medical Society, the late Dr. Clutterbuck related the case of a woman who for seven years had taken two scruples (forty grains) of solid opium daily. She was fifty-four, had led an irregular life, and had first taken opium to relieve the pains of rheumatism. The dose was not increased, and the usual ill-effects of opium were absent—such as constipation, nausea, and loss of appetite. Although she did not increase the dose, the effects of the diminution of a single grain of her usual quantity were most marked, and she felt them immediately. Many cases of this description are recorded by medical authorities; they appear to show that opium-eating has not necessarily that tendency to shorten life which it has hitherto been supposed to have. There is, however, sufficient evidence to prove that the practice gives rise to prejudicial effects on the system, and tends to impair health. It may not have this effect in all cases, except on the withdrawal of the stimulus; but this is not the question. It might be on this principle argued that the drinking of alcoholic liquids has no tendency to shorten life, because some hundreds of cases may be adduced in which the persons have been addicted to intemperate habits for years, and have

still appeared to suffer but little in bodily health. They who have witnessed the effects of opium-eating in Turkey and China agree that the practice leads to the speedy destruction of health. Dr. Oppenheim, in writing on the state of medicine in Turkey, says : " The habitual opium-eater is readily recognized by his appearance. A total attenuation of body, a withered yellow countenance, a lame gait, a bending of the spine (frequently to such a degree as to cause the body to assume a semicircular form), and glassy deep sunken eyes, betray him at the first glance. The digestive organs are much deranged ; the sufferer eats scarcely anything, and has hardly one evacuation in a week ; his mental and bodily powers are destroyed. As the habit becomes more confirmed, his strength continues decreasing, the craving for the stimulus becomes greater, and in order to produce the desired effect the dose must be constantly augmented. After long indulgence, the opium-eater suffers from neuralgic pains, to which opium itself brings no relief. These persons seldom attain the age of forty, if they have begun to take opium early." This description of the effects is exactly what we should expect from physiological and pathological reasoning. Dr. Christison states he has ascertained that constipation is by no means a general consequence of the continued use of opium ; but this may be simply an exception to the rule. It is believed by some that the action of the drug may be different in different countries, and that the description of the effects produced by the use of opium in Turkey cannot be applied to the English opium-eater. The following case, however, which occurred to Dr. Thomson, at University College Hospital, shows that climate has little influence on the effects of this drug :—

E. M., aged 35, was admitted May 26, 1835. About seventeen years ago she began to suffer from a pain in the right iliac region, for which a medical gentleman ordered her to take ten drops of laudanum, night and morning. This was gradually increased, the pain continuing, until at last she took three teaspoonfuls every four hours, day and night. At first the ten drops relieved the pain, but it was found necessary to increase the dose to produce the same effect, so that three teaspoonfuls at last did not produce so much relief as the ten drops at first. The effect of the small doses was simply to produce a relief from pain, without otherwise affecting the body or mind. As the dose was increased, however, she found it to produce a comfortable condition of the mind : she felt lively and cheerful, and was capable of doing any amount of work ; it also caused a sense of warmth over the whole body. She had severe family afflictions, but while under the influence of opium was not at all distressed by them, although she felt them severely at other times. If she passed over the usual time for taking a dose, she had the most distressing sensations about the joints, not of pain, but such as she was unable to describe. She suffered from involuntary motions of the arms, fingers, and toes ; numbness in the limbs and body generally ; profuse perspiration, nausea, vomiting, and loss of appetite ; a saline taste in the saliva, and a bad taste in the mouth ; trembling of the limbs, great debility, and a feeling of lassitude. The memory and mental powers generally became impaired, and there was a great depression of the spirits. These symptoms were all relieved by a repetition of the dose. The opium also

produced constipation—not more than one motion occurring in a week ; and she does not recollect whether that was produced by medicine or not. If the dose was deferred, she had always suffered from severe headache. Her sense of smell was so much impaired that she could perceive no pungency in snuff ; her taste was so much lost that she could not distinguish pepper or mustard ; and her hearing was so defective that she could hardly detect the voice of any one who spoke ; yet her own voice sounded most disagreeably loud to her. Her touch was so much affected that she could not execute any needlework. The acuteness of all her senses was, however, restored by the usual dose, the want of which was indicated by flushing and heat of the face. During the period of taking the opium she had very little sleep, and in the intervals she did not attempt to sleep from want of the desire, so that she generally worked all night. What sleep she had was, generally, during the day, but this was much confused and easily broken. About five or six years ago, her resources being exhausted, she obtained admission into the hospital. The laudanum was here discontinued for the first three days, and all the above symptoms were present ; she now for the first time appeared to see the most frightful spectres of animals and other objects in the ward. The symptoms were again relieved by the usual doses. The doses of laudanum were decreased during the whole time ; and when she left the hospital, she took a teaspoonful only in the course of the day. On returning home, as she was dependent on her friends, she was obliged to discontinue the laudanum and wine, and was unable to get beer ; she was now more miserable than before, all the symptoms returning with increased severity, and for the first six months she was almost entirely helpless. There was pain in the chest with a cough, which had continued ever since. She was twelve months at home before the above distressing symptoms disappeared. The consequences of her opium-eating then observed were a much impaired taste, numbness of the limbs, coldness of the feet, inability to walk far without aching pains in the limbs, and a general sense of lassitude.

There is abundant evidence that this drug, as it has been administered to children in the factory-districts, has produced serious injury to health and great mortality. In the late Mr. Grainger's report on the Children's Employment Commission, it is stated that laudanum and other preparations of opium are given to young children in gradually-increased doses, until the child will bear from fifteen to twenty drops of laudanum at a time. The child becomes pale and wan, with a peculiar sharpness of features, and rapidly wastes away. The majority of these children die by the time they are two years old. These facts appear to show that climate does not at all affect the action of the drug in the early periods of life ; and the observations yet made are not sufficiently numerous to justify us in affirming the existence of this influence with respect to adults. Dr. Christison has remarked that many persons probably die young from the effects of this habit without the secret being discovered ; for even the medical attendant, as well as intimate friends, may be kept in complete ignorance of the person indulging in it. On the whole, we are bound to conclude that the habit of opium-eating is injurious to health, and is therefore calculated to shorten life. In any proposal for life-insurance

the insurers ought to be informed of this habit where it exists, and no medical man should sanction its concealment merely because many persons addicted to it have lived for years in apparently tolerable health. One of the questions put to a medical man is, whether he knows any material circumstance touching the health or habits of the person to which the other inquiries in the certificate do not extend; and if so, he is required to state them. Now, without going the length of saying that the life of an opium-eater is uninsurable upon a common risk, the habit is itself sufficiently material to require that it should be declared in reply to such a question as this. The practice may be, and often is, concealed from a medical attendant; then the insured, if not candid in avowing its existence, must expose his representatives to the risk of losing all benefit under the policy. Independently of medical facts, which appear to favor both sides of this question, a jury would probably be guided to a verdict by the effect actually produced on the constitution of a person who has been addicted to the practice. If it has continued many years, and there is no proof of his health having in consequence undergone any remarkable change, this might be regarded by the jury as the best possible evidence in favor of the concealment not being in such a case material. The insurers could not equitably complain of the verdict in the Earl of Mar's case; for as he began opium-eating at twenty-seven, and died at fifty-seven without any obviously injurious effects being produced by the use of the drug, it could not be said that, in his case at least, the practice had shortened life. It is rarely in our power to apply any better or more practical test than this, under circumstances in which medical facts appear to bear both ways. The case is very different from intemperance in the use of alcoholic liquids: no one can doubt that in this form the results must be inevitably to impair health and to shorten life. The facts here bear one way; and if instances of longevity can be adduced among spirit-drinkers, they are well known and generally admitted to be exceptions to the rule. The queries put by insurance offices are now so explicit, that they must be considered as including the habit of opium-eating; and there does not appear to be any just pretence for evading the admission of the practice, either on the part of the insured, or (if known to him) of his medical attendant.

Tobacco-smoking.—I am not aware that the prevalent habit of smoking tobacco has ever been regarded in relation to life-insurance. Although inveterate smokers are liable to attacks of dyspepsia, loss of muscular and nervous power, weakness, and other derangements of the system, there is not, so far as I know, any evidence to show that the practice has a tendency to shorten life. Should the habit be stated in a certificate? I think it should, if known to the medical referee, and where it is of a most inveterate kind. This would at least prevent objections on the part of the captious company. There is no rule of law on this point, if we except a dictum of Lord Mansfield: "The insured need not mention what the insurer ought to know, what he takes upon himself the knowledge of, or what he waives being informed of: the insurer need not be told general topics of speculation."

Insanity.—When we are called upon to say what *diseases* have a tendency to shorten life, there is commonly no difficulty in giving a reply, since the name of the disease—its known effects upon the body—the degree of mortality produced by it, and its intractableness, are data upon which a medical opinion may be easily expressed. There are some diseases, however, respecting which it is not so easy to return an answer; and among these may be mentioned *insanity*, which has already given rise to discussion in a court of law. The treatment of this malady falls out of the usual line of practice; and there are comparatively few in the profession who have made themselves acquainted with statistical details respecting it. This may account for the decision in the following case:—

In 1835, a trial took place at the York Assizes, in which the question was, whether insanity had, or had not, a tendency to shorten life. The representatives of a clergyman brought an action against the Providence Insurance Company, to recover the amount of a policy effected on the life of a gentleman; but the office refused to pay on account of the person having been insane, and this fact having been kept from their knowledge when the insurance was effected. Several medical witnesses gave evidence on the occasion. One considered that insanity had a tendency to shorten life; another, that it had not; a third, who admitted that the deceased was laboring under insanity, did not consider that *his* mental state was such as had a tendency to shorten life. The judge charged the jury that the question for them to consider was, whether insanity had a tendency to shorten life, as, if so, this would make the concealment of it material. If insanity had such a tendency, they must find for the defendant; if not, for the plaintiff. The jury found for the plaintiff, on the ground that insanity had no tendency to shorten life, and that therefore the concealment was not material.

There is probably no case which more strongly shows the necessity for proper medical evidence on these occasions. The finding of the jury was contrary to all good medical experience, and was founded on a complete mistake. The researches of Esquirol, Farre, and others, show that insanity has a decided tendency to shorten life. So well aware are the insurance offices of this, that the existence, or non-existence of insanity or mental derangement is now made a special question, to which an answer must be given in the declaration. The contrary opinion appears to have arisen from the hypothesis that insanity is not a bodily disease, and in no way connected with physical changes in the structure of the brain. Admitting this statement to be true, experience is decidedly against the inference based on it, when we look at insanity in the aggregate of cases.

There was formerly an erroneous notion that insanity had a tendency to prolong life; but more correct statistical researches have shown that the insane are more liable than the sane to various diseases, and that when attacked they sink more easily under them; hence the mortality of the insane is, *cæteris paribus*, much above the average of that of the sane population. Among other fatal diseases, the insane are especially liable to attacks of paralysis and epilepsy; and paralysis, however slight, is commonly the forerunner of death in these cases. In private asylums, the mortality is always less than in public hospitals; but recent researches

liable to diseases consequent therefrom. Death from "sunstroke" must therefore be considered as arising from natural causes, and not from accident, and judgment will be given in favor of the defendants.

In the case of a person being killed by lightning whose life was insured against accidental death, the question might arise whether such a mode of death was accidental or not. Death by lightning is certainly not a natural cause of death, and in common language any person killed by lightning is said to have died accidentally.

[Where a death takes place in such a manner that it may have happened from natural causes, the assured are not liable unless it is *proved* to have been caused by accident. (*Trew v. Ins. Co.*, 5 Hurls. & Norm. 211.)

A clause in a life-insurance policy provided in cases "of a bodily injury to the insured of so serious a nature as to wholly disable him from following his usual business, occupation, or pursuits," for the payment of £5 per week during the continuance of such disability. The insured, a solicitor and registrar of a county court, was confined to his bedroom for several weeks by a sprained ankle, and was consequently unable to attend to his business. It was held that he was "wholly disabled" within the meaning of the policy, and therefore entitled to recover. (*Hooper v. Accidental Ins. Co.*, 5 Hurls. & Norm. 546.)—P.]

Suicide.—Among the conditions in policies of insurance, there is generally a stipulation in the contract that the policy shall be void if the person who insures his life commits suicide. Thus, a medical question may arise as to whether suicide was, or was not, committed in a particular case. A person may die from poison, wounds, drowning, or other forms of asphyxia; and it may be difficult to say in certain cases whether the death arose from accident, suicide, or from violence inflicted by another. Such cases are often left in great uncertainty at coroners' inquests—the evidence received being imperfect or insufficient; because in cases of sudden death, provided there be no suspicion of murder, it is considered of little moment to make a strict inquiry. If the life of the deceased should happen to be insured under a policy containing this condition respecting suicide, the question may become of great moment to the interest of the insurers, and they will require clear evidence that the death was natural or accidental, and not suicidal, before paying the amount of the policy. The cause of death should in all cases of violence be determined by a medical man: this will put an end to any dispute concerning the payment of the policy, and relieve the representatives from the trouble and expense of litigation. If the death be sudden, and any suspicious circumstances are left unexplained, it is certain that a civil action will follow. We are not therefore safe if, at a coroner's inquest, we suppose that we have only to satisfy a common jury by a hasty opinion expressed from an external view of the body, or an ill-conducted inspection, merely because it may appear to us quite certain that the deceased could not have been murdered. Should the deceased happen to be one of that class of persons on whose lives insurances are commonly effected, the whole of the circumstances connected with the examination of the body, and the medical opinion of the cause of death, must come to

light, and if carelessly performed will probably be made the subject of a severe cross-examination. I have known several instances in which there have been painful exposures of this kind, because the medical witness thought any kind of evidence would serve the purpose of a coroner's jury. The verdict of a jury at an inquest is not binding on a company: they have not only a right, but often good reason to dispute it, and they frequently exercise this privilege. The insurance companies are exposed to all kinds of frauds, some of them of a most fearful kind, actually leading, as in the case of burial-clubs (a kind of life-insurance), to the perpetration of murder for the sake of the small amount insured.

A case of some interest in reference to the question of suicide by poison, on the part of a person whose life had been only recently insured for a very large sum, was tried before Lord Tenterden in 1832 (*Kinnear v. The Rock Insurance Company*); the late Mr. J. H. Green, Mr. Key, and myself were called upon to give evidence on the part of the defendants. This trial would not have occurred but that the medical inspection of the body for the inquest two years previously had been most improperly conducted, and no satisfactory evidence of the cause of death assigned. As a sum of 10,000*l.* rested upon the issue, the insurers felt that they had a right to demand a full and perfect inquiry. The depositions taken at the inquest on decease were sent to me for examination, and from these it appeared that the person whose life was insured died two years before the action was brought; the body was carelessly inspected for a coroner's inquest, and the contents of the stomach, without being subjected to any chemical analysis, had been thrown away. These circumstances placed great difficulty in the way of producing proof, and in fact, so far as medical evidence was concerned, they left the question almost a mere matter of opinion. An application was made to me on the part of the insurance company, to know whether the exhumation of the body and any further processes of analysis would be attended with any benefit, but an answer was returned in the negative. From the manner in which the first examination had been conducted—also from the fact that, as the symptoms under which the deceased had died could only have been presumptively those of narcotic poisoning, it was altogether improbable that, after two years' interment, any trace of narcotic poison would be discovered in the remains.

The deceased—who, according to the evidence given at the trial, had been for some time in a low state of mind—returned to his house, in the Regent's Park, on the evening of the 19th October, 1830. The house was then undergoing repair; his family were in the country, and the only person residing with him at the time was a man-servant. The account given by this person was that the deceased returned home about ten o'clock in the evening, apparently in his usual health: he ordered him to place a decanter of wine, a tumbler, and a wineglass on the library table adjoining his bed-room; told him that he was going to take a composing draught, and desired that he might not be called on the following morning, saying that he would ring his bell if he wanted anything. The deceased went to bed, but about twelve o'clock the servant was awakened by a noise, as if the bar of the library-shutters had fallen. On getting up, he saw his master, without a light, in the act of returning

from the library to his bed-room, which adjoined it; he took a light from witness, and again went to bed. On going up stairs ten minutes afterwards, witness found the light extinguished, and the door of the deceased's bed-room fastened. On the next morning, at 9.30, witness went to deceased's bed-room, and knocked at the door as usual, but received no answer; he went again at ten o'clock, but the door was still fastened, and the deceased did not answer when he knocked. The workmen who were employed in the house alarmed witness, about twelve o'clock, by telling him that they had heard his master moaning or groaning. A ladder was then procured, and the room was entered by the window. The deceased was in bed, and appeared to have just died as the witnesses entered. A surgeon was immediately sent for, who on his arrival examined and tasted some liquid which was found in a tumbler on the table. Search was made for a phial, but none could be found; however, it was proved that there were on the library table a piece of blue and a piece of red paper, evidently the cover and wrapper of a phial, which were not there previously. It was also deposed that a cork and string were found in the fireplace. The window of the library was open, the shutters having been unfastened.

The surgeon, who was called, stated that the body was lying in a composed state, the countenance being somewhat pale. There was perspiration on the skin, with patches of a livid color here and there distributed over it. The body was inspected for the coroner's inquest by two physicians and two surgeons. An accumulation of putrid blood is said to have been found in the stomach, with an effusion on either side of the chest. The vessels of the brain were somewhat turgid, but there was no extravasation. The contents of the stomach were thrown away without any chemical analysis having been made. It appears that the only approach to analysis was the drawing of a stick of nitrate of silver across the mucous membrane of the stomach at the time of the inspection. The cause of death assigned by these witnesses was the rupture of a blood-vessel in the stomach. A verdict of "Death from natural causes," was returned; the body was buried, and it was supposed that all inquiry had ceased.

The cause of death assigned by the witnesses being considered altogether inadequate to account for this event under the circumstances—the suddenness of death in a person who was in perfect health the evening before—the absence of any sign of effusion of blood in the brain, so frequently met with in sudden death from apoplexy—together with the circumstantial evidence that some liquid had been taken by deceased, and the phial disposed of, afforded a strong ground for suspicion. The insurers refused payment of the amount of the policy, and demanded an inquiry.

The circumstantial evidence not being of itself sufficient to establish the fact of poisoning, additional evidence was required to determine—1. Whether the cause of death assigned by the witnesses at the inquest was adequate to account for it; and 2. Whether, if not, the facts proved relative to the death of the deceased, were consistent with narcotic poisoning—whether, in short, death by poison was, or was not probable.

Mr. Green, Mr. Key, and myself were requested to give an opinion

on these points. With regard to the first, we said the cause of death assigned by the witnesses was inadequate and unsatisfactory. The blood found in the stomach was loosely described as half-putrid and not coagulated ; so far from its being proved that it had been effused during life, it was not improbable, from the careless manner in which the inspection was made, that it had proceeded from some vessels divided by the examiners. Admitting that it had been effused during life, it did not furnish a satisfactory explanation of the cause of death, since the quantity was small. That it was not satisfactory to the inspectors themselves appeared certain from the fact that they examined the stomach for some kind of poison by the rough experiment of drawing a stick of nitrate of silver over the mucuous membrane ! Further, gastric hemorrhage rarely destroys life on a first attack, and is generally accompanied by vomiting of blood ; but the deceased had never been subject to hæmatemesis, and there had been no bloody vomiting.

With regard to the second question, the facts proved might be explained by supposing that the deceased had taken a poisonous dose of laudanum, or of some preparation of opium ; it might be contended that no opiate was present in the stomach, but it did not appear that any analysis had been made. The deceased had died in about the period at which this poison operates fatally, and it was for the jury to determine from the circumstantial evidence, as the medical evidence wholly failed to throw light upon the subject, how far this was likely. We all agreed that narcotic poisoning in the deceased's case was, so far as we could speak in the absence of an analysis, probable, inasmuch as the facts proved respecting his death agreed with this view, and the results of the medical inspection so far as they went were quite consistent with it. On the other hand, the question might arise whether there were no natural causes which would have destroyed life within twelve hours in the same tranquil manner in which the deceased was supposed to have died. To this it may be replied, that apoplexy and other diseases might also have accounted for death ; but there was no evidence from the inspection to establish the existence of these, and death from a narcotic poison was, medically speaking, just as probable. In short, as the evidence was essentially of a negative kind, and there were two ways of accounting for death, either of them consistent with the medical facts, it remained for the jury to decide from the whole of the circumstances which was the more probable. The cause of death was entirely a matter of medical presumption. It was impossible to swear that the deceased could not have died from apoplexy, or from the effects of a large dose of an opiate. As the case was only one of *suspicion*, and not of actual *proof*, a verdict was returned for the plaintiff.

There can be no doubt of the propriety of the verdict, since the law always justly insists upon what the circumstantial evidence, combined with medical opinions, was here incapable of affording—namely, *direct* and not inferential *proof* of death from poison. The insurers had alleged suicide by poison—this they were bound to prove by clear and distinct evidence ; the plaintiff was not required to show that the death was natural. If, besides the paper wrappers, string, and cork, a phial which had evidently contained laudanum, had been found, or the liquid in the

tumbler, instead of being merely tasted or smelt by the medical gentleman and then thrown away, had been carefully analyzed, or had the same cautious proceedings been adopted with regard to the contents of the stomach, clear evidence might have been adduced which would have satisfied the jury that the deceased had died from narcotic poison. In supposing that the deceased took a fatal dose of an opiate, it was assumed that he had disposed of the bottle by throwing it out of the library window, which was found open after the shutters had been fastened; no traces of the *composing draught* which he had told his servant he should take were found—not even the phial—and the colored wrappers of paper, cork, and string found in the bedroom were not accounted for.

The only point that went against the presumption of narcotic poisoning was this: the servant swore on the trial that his master's bell rang about nine o'clock. If this were true, the deceased could not then have been under the influence of a narcotic poison, as he must have walked across the room to have rung the bell. This would have given but *three hours* for the fatal operation of the poison, while most cases of poisoning by opium have not proved fatal in less than from six to twelve hours. Still, opium has been known to cause death within a short period. Sir R. Christison met with a case where the person died in three hours, and Dr. Beck another, where death occurred in two hours and a half. But on comparing the evidence of this witness at the inquest and the trial, there was a great discrepancy. He said nothing of a bell ringing when examined at the inquest recently after his master's death (*i. e.* two years before the trial), when it might be supposed that the whole of the circumstances were fresh in his mind.

Among the medico-legal questions connected with this subject is the following: Does the proviso in the policy respecting suicide include all acts of self-destruction, or is it restricted only to those cases in which either a sane or a partially insane person consciously destroys himself? This question has been elsewhere considered (Chap. 67). The act of suicide does not necessarily indicate insanity; but even if it did, the rule of law, as settled by a majority of the judges in reference to this proviso in cases of life-insurance, is that whenever an insured person destroys himself *intentionally*, whatever may be the state of his mind, the policy is void. If a person, whether sane or insane, kills himself *unintentionally*, then the insurers are liable; but the onus of proof in this case lies upon the plaintiffs, *i. e.*, those who would benefit by the policy. According to the practice of some offices, the act of suicide does not render a policy void.

[The leading English cases on this subject are *Borradale v. Hunter*, 5 Mann. & Grang. R. 639, and *Cleft v. Schwaibe*, 3 Mann., Grang., & Scott R. 437. In the former case, the provision was that the policy should be void if the assured "should die by his own hands." The assured threw himself into the Thames and was drowned. The jury found, however, that though this was done voluntarily, and with intent to destroy life, the assured "was not capable of judging between right and wrong." The majority of the court held the policy to be avoided.

Chief Justice Tindal dissented, delivering a very able opinion sustaining his views.

In the other case, the policy provided that it should become void if the assured "committed suicide." He did, in a fit of insanity, commit suicide by taking sulphuric acid. Creswell, J., directed the jury that they must find for the plaintiff unless the assured, when he died by his own voluntary act, "was able to distinguish between right and wrong, and to appreciate the nature and quality of the act that he was doing, so as to be a responsible moral agent." Upon a bill of exceptions, this instruction was held to be erroneous, the majority of the court being of opinion that it was immaterial under the terms of the policy, whether the assured was, or was not at the time a responsible, moral agent. Chief Baron Pollock and Justice Wightman dissented, on the ground that as "soon as it is ascertained that a person has lost his sense of right and wrong, it matters not what else of the human faculties or capacities remain, and that he can no more commit suicide than he can commit murder."

The same question arose in *Breasted v. Farmers' Loan and Trust Co.*, 4 Hill (N. Y.) R. 73; affirmed in 4 Seld. 299. The policy in that case provided that it should become void in case the assured should "die by his own hand." He committed suicide by drowning himself in the Hudson River, being at the time of "unsound mind, and wholly unconscious of the act." The case came before the court upon a demurrer. Nelson, C. J., delivered the opinion of the court, giving judgment for plaintiff.

A similar decision has recently been made by the Supreme Court of Maine upon an insurance effected by Joseph Esterbrook, who afterwards became deranged, and committed suicide by shooting himself. ("Legal and Insurance Reporter," Sept. 1866, p. 281.)

As to the construction of the words "die by his own hand," see *Hartman v. Keystone Ins. Co.*, 9 Harris (Penna.) 466.—P.]

[It appears only consistent with common justice, as well as in accordance with the above quoted judicial decisions, that a death by suicide, *if proven to have resulted from insanity*, should *not* render void a policy of life-insurance, no matter what be the printed proviso in said policy in relation to the assured "dying by his own hand." Suppose that a person, suffering from a fever accompanied by an active delirium, should, under the cerebral excitement, throw himself out of the window, or drown himself in a neighboring well, ought he to be held morally accountable for the act? Is not his death as clearly the result of *disease* as if he had died in his bed, of convulsions or coma?—R.]

M. Brierre de Boismont reports a case which is also instructive in reference to this difficult question. On the 12th of October, 1840, a man was found dead, apparently strangled, on the road to Stettin. His affairs were found to be in an unsettled state, and it was supposed he had destroyed himself; but the position of the body, and the condition in which it was found, were apparently not consistent with this theory. The hands were tied behind the back, and there were the appearances of a robbery. As all the circumstances pointed to a violent death at the hands of another, a judicial inquiry was made, which, from want of

evidence, led to no important result. The deceased, who was a merchant, had recently effected an insurance on his life for the amount of 40,000 francs, which was to be paid to his family on his death, except in case of his committing suicide. This sum was paid into court, and was subsequently reclaimed by the office, on the ground that the deceased had destroyed himself. A witness had come forward with an autograph letter of the deceased, in which he had described the motives that had led him to perpetrate the act, and the mode in which he had carried out his design. This document clearly proved that he had sacrificed his own life for the sake of his family, in order to preserve them from impending ruin. According to the private letter to his friend, which had every appearance of authenticity, he had suspended himself to a beam, from which a friend, according to a previous arrangement, had cut him down, and had then disposed of his body on the high road, under such circumstances as to give the impression that he had been the victim of a murderous assault. ("Ann. d'Hyg.," 1866, 2, 397.) The attempt thus made to defraud the insurance company by hastening the term at which the insurance would fall in, and by falsifying the conditions of the policy, was defeated by the production of a private letter.

There is another kind of fraud which perhaps is more common, namely, that in which the insured simulates death in order that his relatives or creditors may receive the amount of the insurance. Two instances of this kind of fraud have been related in a former part of this work. In one, the insurer endeavored to make it appear that he lost his life while bathing on the sea-shore, his clothes being found on the steps of a bathing-machine; in the other, the case of a fraudulent bankrupt, the man registered his own alleged death, and followed his own coffin to the grave in a country churchyard! In both cases the fraud was detected, and the offices were saved from a heavy loss.

It is naturally supposed that a man has a direct interest in preserving his own life, but this of course will not prevent him from falling a victim to the criminal designs of another. The insurable interest of a person in the life of another became an important question in January, 1863, in *Hebdon v. West*. The plaintiff, a clerk in a banking-firm, had effected an insurance on the life of one Pedder, who was a member of the firm. Plaintiff became indebted to the firm for a sum of 5000*l.*, and Pedder having informed the plaintiff that he should not be troubled with any demand for repayment during his (Pedder's) life, the plaintiff insured Pedder's life in the defendant's company for the sum of 2500*l.* It was the payment of this sum to the plaintiff that was now in dispute, the defendant contending that plaintiff had no insurable interest in the life of Pedder. The case was argued, and the court put to counsel the cases which had been already decided, of a father insuring his son's life, or a husband his wife's. It had been held that in these cases there was no insurable interest. Hence, when a husband desired to make a provision for his wife, he insured his own life—she did not insure his. Further, they instanced the remarkable case of *Wainwright* (p. 909), in which that person induced his sister-in-law to insure her life, and then poisoned her, in order, as next of kin, to get hold of the sum assured. That case

showed the immense importance of the law requiring a real interest in the life of a person whose life was insured. The result of the argument was that the court reserved its judgment; but there appeared to be no agreement concerning what was a legal insurable interest in the life of another. [See *Reese v. Mutual Ins. Co.*, 23 N. Y. (9 Smith) 516; *Rawls v. Insurance Co.*, 36 Barb. (N. Y.) 337. In the latter case it was held that a creditor's insurance upon the life of his debtor was not invalidated by the running of the statute of limitations against the debt before death.—P.]

Insurance murders.—The insurance of lives has been considered to be objectionable, on the ground that it tends to create an interest in the death of another, and thus to lead to secret acts of murder. The 14th George III., c. 48, expressly enacts that no insurance on life shall be valid unless the person insuring has a direct legitimate interest in the person whose life is insured. This statute was enacted for the purpose of preventing gambling in policies, and to guard society against the risk of persons insuring contriving the death of the insured for the sake of the payments to be made under the policy; but its effect is simply to render the policy void; it does not require that the premiums shall be refunded, nor does it award any penalty on the offenders. As policies of life-insurance may be bought and sold like other property, they may fall into the hands of persons who have no other interest in them than the desire that such policies should speedily become claims by the death of the insured. The interest of such holders, it has been justly observed, lies in the *death* and not in the *life* of the insured.

[In a recent case in Pennsylvania, *Elliott's Executor's Ap.*, 14 Wright, 75, it was decided that the assignment of policies of life insurance by a debtor who was insolvent when insured, in trust for the benefit of his wife, is fraudulent and void as against creditors; but that policies effected without fraud directly and on their face for the benefit of the wife and payable to her, are not fraudulent as to creditors.—P.]

A case is related in which a man was found dead at St. Fergus, in Scotland, from a pistol-shot wound under very suspicious circumstances. The medical and moral facts were not consistent with the theory of suicide; on the contrary, they all pointed to a cool and deliberate act of murder. A medical man was placed on his trial for this alleged crime, and the motive assigned for the act was that the prisoner had recently effected insurances in three different offices to the amount of about 2000*l.*, upon the life of the deceased—a poor man, in whose life it was proved he could have had no lawful pecuniary interest. The insurances were only for short periods, and as in the Scotch offices the policies are not rendered void by suicide, the amounts could be claimed even assuming that the deceased had destroyed himself. The body, weapon, and other objects had, it was supposed, been arranged with a view to make it appear that the act was suicidal. It is a significant fact, however, as a key to explain the death of the deceased and the motive of the accused, that the risk connected with the largest insurance (1000*l.*) commenced on the 24th November, 1852, and terminated on the 24th November, 1853. Only one premium to the amount of about eleven pounds had

been paid, and this payment was proved to have been made by the prisoner. The deceased was found dead on the 20th November, 1853; *i. e.*, only four days before the date at which the policy of insurance on his life would have lapsed. The evidence went to show that the accused had the motive, means, and opportunity of committing this crime; but as there were no circumstances which could directly fix it upon him, he was acquitted of the charge.

A remarkable case was tried in this country in 1835 (*Wainwright v. Bland*, Exchequer, 29th June, 1835), in which the amount of a policy of insurance effected for two years on the life of a *Miss Abercromby* was sought to be recovered. The action was brought against the Directors of the Imperial Assurance Company, and was resisted by them on the grounds that the lady had been destroyed by poison, and that the plaintiff *Wainwright* had no lawful pecuniary interest in her life. As there is strong reason to believe that this was one of the first murders brought about by the use of strychnia in this country, it may be considered as the type of those which twenty-one years afterwards were for a time successfully perpetrated by the criminal William Palmer. Strychnia had been discovered only twelve years previously, and it was then but little known as a poison either in England or France. The history of the case is remarkable, as the real cause of death was completely overlooked. Two fine-looking young women of the name of *Abercromby*, the daughters of a deceased officer, with no other property than pensions of ten pounds a year from government, lived a few miles out of town with a man of the name of *Wainwright* and his wife, who were also in reduced circumstances. They came to London in 1830, as the winter was setting in, and took lodgings. The elder girl, having just attained her twenty-first year, was sent, sometimes alone and sometimes with her sister, to no fewer than eight or ten insurance offices, to effect insurances at each on her own life. Being in full and vigorous health, she met with a favorable reception from several offices, although she could assign no other reason for wishing to insure her life than that she was told it was right for her to do so. Five offices granted policies in her own name, some for two, others for three years, for no less a sum than 16,000*l.* Among them the Imperial, in October, 1830, accepted an insurance on her life for two years for 3000*l.* On the 13th of the following December, when in perfectly good health, she made her will, and assigned this and other policies to the plaintiff *Wainwright* and his wife. On the evening of this day the whole party went to a public theatre, and on their return had a supper of oysters and porter. On this occasion *Miss Abercromby* was first taken ill; it was said she suffered from an hysterical attack, but there is no clear account of her illness at this time. It was not until the 16th that she was seen by a physician, but her illness was not such as to excite alarm; it was supposed to be hysterical. On the 21st this physician was called suddenly to her, and he then found her in violent tetanic convulsions, resembling those which are sometimes the effects of a wound, *i. e.* *tetanus*. She said she was sure she would die, and she suddenly went off into a fit of convulsions. The physician left the house, returned in about an hour, and she was then just dead. The appearances presented by the body are imperfectly reported; there was an

effusion of serum at the base of the brain, and to this death was referred. There was no analysis of the contents of the stomach ; it is said they were minutely examined, and that there was no appearance of anything sufficient to account for death ; but the person to whom this examination was intrusted was not called to the trial.

Wainwright, as executor and trustee, applied for payment of two of the policies which had been assigned to him, but this was refused. He then went to France with his family, and five years afterwards (in 1835), through an agent, brought an action against the Imperial Assurance Company. On this occasion the jury could not agree in a verdict. ("Med. Gaz.," vol. 16, p. 606.) Another action was afterwards brought against the company, and the facts above stated came out at the trial. The Attorney-General said that the plaintiff had left the country, and there was good reason to believe that he would never again return to it. The judge charged the jury that, whether murder had been committed or not, the executors could recover, provided the insurance had been effected *bonâ fide* on behalf of the deceased. His lordship directed their attention to the extraordinary fact of this young lady, the deceased, having effected these large insurances for only *two* years ; of her sudden illness and death in convulsions soon after the assignment of the policy ; and reminded them that no proof had been adduced to substantiate the reasons she had given to the various offices for effecting the insurances on her life. By the will and assignment made to the plaintiff and his wife, these persons were placed in a situation in which the law would not allow any one to stand—namely, that of having a strong interest in procuring the death of a fellow-creature by unlawful means. The jury returned a verdict for the insurers, on the ground of misrepresentation and want of interest.

There can be no doubt that this young woman died from the effects of a dose of strychnia, administered to her shortly before she was seen by the physician on the afternoon of the 21st December. Tetanus, as it is produced by this poison, is rapidly fatal ; but as it arises from wounds, it comes on slowly, and is only fatal after some days ; and there was no wound, or other natural cause to account for its occurrence. Wainwright was subsequently tried, convicted of forgery, and transported. He died many years afterwards in one of our penal settlements, and, before his death, it is reported that he substantially admitted that he destroyed Miss Abercromby and several other persons by strychnia.

Some of the poisonings which took place at Rugeley in 1855-6, and which culminated in the conviction and execution of the notorious *William Palmer* for the murder of J. P. Cook, originated in the easy system of raising money by the insurance of lives. The body of Ann Palmer, the wife of the prisoner, had been lying fifteen months in the grave, under a professional burial certificate of death from *bilious cholera*, when the sudden death of Cook and the detection of antimony in his body, led to the exhumation of the body of this lady. It was then found that she had died from the effects of antimony, which was detected by Dr. Rees and myself in all parts of the body, even in the ovaries. When the history of the illness which preceded death was gone into, it was found that the symptoms were consistent with the effects of tartarized antimony,

but not with those of bilious cholera, or any other disease. Antimony had not been prescribed for the deceased during her illness, and it was therefore clear that it must have been administered to her by some one, up to within a short period of her death. With an actual life interest in his wife's property to the extent of only 3000*l.*, and within the short period of nine months of her death, *William Palmer* made, or caused to be made, proposals for insuring her life in eight different offices, for an aggregate sum of 33,000*l.* Three of these proposals made by *himself*—to the Norwich Union in December, 1853, for 3000*l.*, to the Scottish Equitable in January, 1854, for 5000*l.*, and to the Sun in February, 1854, also for 5000*l.*—were accepted by these offices. He thus contrived in less than three months to effect a total insurance of 13,000*l.* to cover a life-interest of 3000*l.* on his wife's property! The other proposals, to the amount of about 20,000*l.*, were declined by the offices to which he applied. The total premiums paid by *Palmer* on the three policies amounted to 388*l.*; and he was at the time so pressed for money, that he drew a bill which was actually discounted on the security of the policies, so that he contrived to make the policies pay for themselves. As he was in embarrassed circumstances, and unable to meet bills of this kind without becoming still more deeply involved in debt, the realization of the policies by the death of his wife became to him a matter of necessity. Within little more than six months after effecting the insurance on her life, the wife died from poison, under his immediate superintendence. On her death, these large sums were claimed by *Palmer*, and were paid to him by the offices. Although there was at the time some suspicion that the wife had died from poison, there was no inquest or inspection, and the body was hastily buried. These facts only came to light more than a year afterwards, during the investigation of another murder in 1855. It seems that the general respectability of *Palmer*, his social and professional position, together with the two medical certificates of the cause of the death of the wife, checked any intention which might have existed on the part of these offices to resist the payment of the policies. *Wm. Palmer*, however, carried his life-insurance speculations much further than this. Having no pecuniary interest whatever in the life of his brother, Walter Palmer, he either made or induced him to make proposals for the insurance of his life, in various offices, to the amount of 82,000*l.* The Prince of Wales office accepted the proposals to the extent of 13,000*l.* under certain limitations. On the 16th August, 1855, Walter Palmer died suddenly, in the presence of his brother and another man of doubtful character, with whom he had recently placed him as a lodger; and it was rendered highly probable, if not proved, that the prisoner *William* had shortly before purchased at a druggist's a bottle of prussic acid. The policy had been previously assigned by Walter to *William*, for a nominal consideration; but when *William Palmer* made application for the amount after the death of his brother, the office refused payment; and, for very good reasons, *Palmer* failed to enforce it. He subsequently tried, but ineffectually, to insure, to the extent of 25,000*l.*, the life of his groom, George Bates, described by him in his proposal as a "gentleman" of independent means; and he advised a man named Cheshire, the postmaster of Rugeley, also to make proposals on his life to the extent

of 5000*l.* and assign the policies to him. But connected with the death of Cook, these two heavy life-insurance value had thus been set, victims. Thuggism, as formerly perpetrated in of Hindoos, might be regarded as a venial offence, professional mode of raising large sums of money.

It is now the custom of offices to require a statement has been already proposed to other offices, and has, or has not been accepted. But this is only checking such nefarious speculations. In France, States, insurances of this kind are said to be established for the prevention of gambling (which is rather endeavored to guard society against the risk of the persons death of the insured. That these regulations are against secret murder and speculation in human life, established by the case of *Dr. De la Pommerais* was convicted in Paris of the murder of a woman; reader will find an account of the medical circumstances of this act of murder, which equals, if it does not surpass, the murders perpetrated by William Palmer on his wife, 2, p. 438, of "The Principles and Practice of Medicine," 1878.

De la Pommerais had first cohabited with a woman, thrown her off, he married, in August, 1861, a woman named Madlle. Dubizy. Some time after the marriage, she died under very suspicious circumstances, as it was administered by the prisoner. In June, 1863, he, without any apparent cause, renewed his intimacy with her. She was living in great poverty with several children, and he advanced to her small sums of money, amounting to 27*l.*, he induced her to insure her life in various offices for the sum of 22,000*l.*, and afterwards to assign the policies to him, for reasons which he gave for effecting these insurances, he had advanced to the deceased large sums of money, partly that, in the event of her death, he wished to provide for his legitimate children. The first statement was proved true, the second was inconsistent with the claims which he made to the offices. The woman was examined, found to be insured on her life were effected for two or three times the amount above stated. *De la Pommerais* paid the first premium of 600*l.* He had thus entered into engagements with the offices for premiums a sum of about 800*l.* per annum, which would bring in more than 400*l.* per annum, and he lived on the interest. He induced the deceased to feign that she was ill from an accident; but the surgeons and physicians whom he consulted, on examination, that there was nothing the matter with her, but the continuation of a few attacks of vomiting. She continued ill till the end of November, when the prisoner visited her, and attended her with her. She was taken very ill that night, and died, with convulsions, with fainting, she died on the morning of the 12th.

it was proved, from the effects of *digitaline*,—a large quantity of which the prisoner had purchased some time before, and of the disposal of which he could give no satisfactory account. He found no difficulty, however, in procuring a medical certificate to the effect that deceased had died from gastritis and perforation of the stomach. The policies of assurance had been assigned to him by the deceased shortly before her death; and it was the early claim which he put in for the payment of them that first led to suspicion. There was no answer to the charge of murder by the administration of digitaline, and the prisoner was convicted and executed.

The proper method to stop this secret system of murder would be by placing severe legal restrictions on the sale or assignment of policies, and by preventing the purchase of them by strangers, who can only have an interest in the death of the insured at the earliest possible period. The burial-club murders are said to have been much checked by a regulation which prohibited a person from recovering under this species of insurance more than the amount proved to have been actually paid for the funeral. It would be well if this principle were universally carried out, but from the evidence given at the trial of Mary Ann Cotton (*Reg. v. Cotton*, Durham Lent Assizes, 1873), there is reason to believe that insurances on lives are still secretly effected simply for the purposes of murder. The prisoner was indicted for the murder by poison of her stepson, who died in July, 1872. The body of the deceased was exhumed, and arsenic was detected in it. This was the sole cause of death. This woman, it was stated upon well-ascertained facts, had at different times killed by poison her mother, fifteen children, three husbands and a lodger—making altogether twenty persons; and the lives of most, if not all, of them were insured. In some of these cases she had claimed, and received from the insurance offices, the premiums on these deaths. One of her three husbands thus disposed of, and four of her children were insured in the British and Prudential Insurance Office. They died rather rapidly one after the other, and the medical man assigned gastric fever as the cause of death, when the symptoms were not consistent with this cause. The prisoner obtained from the office a sum of thirty-five pounds by the death of this husband, and some smaller amounts from burial-clubs, by the deaths of the children. She then married a man with a family of children, and was very anxious to have his life and the lives of his children insured. One day he found her at an office trying to procure an insurance on his life. He left her, and his life was thereby saved. This woman was very properly convicted and executed. No toxicomania was pleaded in defence! It is clear from the evidence in this and other cases, that some of the insurance offices which find clients among the poor, furnish great facilities for such murders, and that the managers are not sufficiently careful in making inquiry into the means, motives, and objects which induce persons in this class of life to effect insurances on the lives of others.

The trial and conviction of this criminal for these insurance murders brought to light another fact, namely, the great insecurity of life in this country, owing to the perfunctory manner in which medical men discharge an important duty in filling up certificates of the causes of death. With

fully-marked symptoms of arsenical poisoning, these sudden and violent deaths were registered, one after the other, as gastric fever. A public writer, commenting on these cases, justly observes: "Are the symptoms of arsenical poisoning so subtle that trained doctors cannot be expected to notice them? Is it creditable to medical science that a man should be allowed to die with a fatal quantity of arsenic in his stomach without foul play being suspected? But perhaps the greatest wonder is, that a woman could successfully practise for so many years a system of poisoning, without betraying her dreadful secret, or awakening more than once material distrust among her neighbors." The success of this criminal depended, first, on the facilities for insuring the lives of others in a low class of insurance offices, and, secondly, on the carelessness with which causes of death are certified.

 impotency depending on, 724
 of the new-born child, rules for determining, 596
 Air, in veins, a cause of death, 380
 confined, suffocation from, 503
 of drains and sewers, composition of, 513
 Alcohol, poisoning with, 216
 analysis of, 218
 Algaroth, powder of, 178
 Alienation, mental (see **INSANITY**), 777
 Alkalies, poisoning with, 122
 Alkaline poisons, 122
 Allotropic phosphorus, 134
 Almond-flavor, 214
 Almonds, bitter, essential oil of, 214
 Aloes, noxious effects of, 183, 577
 Amanita citrina, death from, 227
 Ambidextrous persons, wounds by, 282
 Amenorrhœa, 541, 577
 a cause of insanity, 733
 Amentia, 785
 Ammonia, poisoning with, 123
 vapor of, fatal effects of, 123
 carbonate of, 125
 Ammoniated mercury, 164
 Ammonio-chloride of mercury, 164
 Ammonium sulphocyanide, 210
 sulphide of, 513, 641
 Amnii, liquor, stains of, 593
 Amorphous phosphorus, 134
 Analysis, articles preserved for, 27
 fallacies connected with, 27
 chemical reports of, 29
 Androgyni and androgynæ, 710
 Animal irritants, 190
 Animirta cœculus, 225
 Antimony, tartarized, poisoning by, 174
 chronic poisoning by, 176
 detection of, in the tissues, 179
 chloride of, 179
 Apnea, death from, 59, 415
 Apoplexy, 60, 89, 365
 meningeal, 368
 Aqua fortis, 110
 Areolæ of the breasts.

- Arrowroot, detection of, 627
 Arsenates, alkaline, 154
 ARSENIC, white, 136
 eating, 83
 symptoms caused by, 136
 chronic poisoning with, 137
 post-mortem appearances, 138
 death from external application of, 139
 analysis as a solid, 141
 fatal dose of, 140
 in solution, 142
 Marsh's process for, 144
 Reinsch's process for, 144
 in organic mixtures and tissues, 145
 not a constituent of the body, 151
 sulphides of, 155
 acid, 154
 chloride of, 155
 Arsenious acid (see ARSENIC), 136
 Arsenites, alkaline, 151
 Arsenite of copper, 152
 symptoms caused by, 152
 in paper-hangings, 153
 Arsenuretted hydrogen, 156
 tests for, 144
 Arterial and venous blood, 301
 Arteries, wounds of, 378
 Artificial inflation of the lungs, 615
 Asphyxia, death from, 59, 415
 syncopal, 59
 various forms of, 415
 from mechanical causes, 475
 from gases, 488
 Assault, marks of blood on the, 271

THE NATIONAL DISPENSATORY—New Edition—Now Ready.

THE NATIONAL DISPENSATORY; CONTAINING THE NATURAL HISTORY, CHEMISTRY, PHARMACY, ACTIONS AND USES OF MEDICINES, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. By ALFRED STILLÉ, M.D., LL.D., Prof. of Theory and Practice of Medicine and of Clinical Med. in the Univ. of Pennsylvania, and JOHN M. MAISCH, Ph.D., Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Sec'y to the American Pharmaceutical Association. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of sixteen hundred and ninety-two pages, with two hundred and thirty-nine illustrations. Extra cloth, \$6 75; leather, raised bands, \$7 50; very handsome half Russia, raised bands, open back, \$8 25.

The author may be congratulated on the execution of a very valuable work, rich in information, and almost encyclopædic in character. This volume must be considered of great value as a work of reference, and one which fully sustains the high reputation of its distinguished authors.—*Dub. Journ. of Med. Sci.*, April, 1880.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since its publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Journ. of Pharmacy*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Med. Journ.*, Nov. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practicing physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

DUNGLISON'S MEDICAL DICTIONARY—Late'y Issued.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: containing a concise explanation of the various subjects and terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence, and Dentistry. Notices of Climate and of Mineral Waters; Formulæ for Official, Empirical, and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes, so as to constitute a French as well as English Medical Lexicon. By ROBLEY DUNGLISON, M.D., late Prof. of Institutes of Med., etc., in Jeff. Med. Coll., Phila. A new edition, thoroughly revised, and very greatly modified and augmented, by RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, \$6 50; leather, raised bands, \$7 50; half Russia, \$8.

ATTFIELD'S CHEMISTRY—Just Issued.

CHEMISTRY, GENERAL, MEDICAL, AND PHARMACEUTICAL; including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. By JOHN ATTFIELD, Ph.D., Prof. of Practical Chemistry to the Pharm. Society of Great Britain, etc. Eighth edition, revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, \$2 50; leather, \$3.

FOWNES' CHEMISTRY—Just Issued.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical. Revised and corrected by HENRY WATTS, B.A., F.R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and 177 illustrations. By GEORGE FOWNES, Ph.D. A new American, from the twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M.D. In one large royal 12mo. volume of over 1000 pages. Cloth, \$2 75; leather, \$3 25.

TAYLOR ON POISONS.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE. By ALFRED S. TAYLOR, M.D., Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital. Third American, from the third and revised English edition. In one large octavo volume of 850 pages. Cloth, \$5 50; leather, \$6 50.

HENRY C. LEA'S SON & CO., Philadelphia.

THOMAS ON WOMEN—New and Revised Edition—Now Ready.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. GAILLARD THOMAS, M.D., Prof. of Obstetrics, etc., in the College of Physicians and Surgeons, New York. Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with about 270 illustrations. Cloth, \$5 00; leather, \$6 00; half Russia, \$6 50.

EMMET'S GYNÆCOLOGY—Just Ready.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the Use of Students and Practitioners of Medicine. By THOMAS ADDIS EMMET, M.D., Surgeon to the Woman's Hospital of the State of New York, etc. Second edition, thoroughly revised. In one very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, \$5; leather, \$6; very handsome half Russia, \$6 50.

LEISHMAN'S MIDWIFERY—New Edition—Just Ready.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE. By WILLIAM LEISHMAN, M.D., Regius Professor of Midwifery in the University of Glasgow, etc. Third American edition, revised by the author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Phila. Hospital, etc. In one large and very handsome octavo volume of 733 pages, with over 200 illustrations. Cloth, \$4 50; leather, \$5 50; half Russia, raised bands, \$6.

SMITH ON CHILDREN—New Edition—Now Ready.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. By J. LEWIS SMITH, M.D., Clinical Professor of Diseases of Children in the Bellevue Hospital Medical College, New York. Fourth edition, revised and enlarged. In one handsome octavo volume of about 750 pages, with illustrations. Cloth, \$4 50; leather, \$5 50; half Russia, raised bands, \$6.

HAMILTON ON FRACTURES—New Edition—Just Ready.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. By FRANK H. HAMILTON, M.D., LL.D., Surgeon to Bellevue Hospital, New York, etc. Sixth edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, \$5 50; leather, \$6 50; half Russia, raised bands, \$7.

BUMSTEAD ON VENEREAL DISEASES—New Edition—Now Ready.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES: Including the results of recent investigations upon the subject. By FREEMAN J. BUMSTEAD, M.D., LL.D., late Professor of Venereal Diseases in the Coll. of Phys. and Surg., New York, etc. Fourth edition, revised and largely rewritten with the co-operation of R. W. TAYLOR, M.D., of New York, Prof. of Dermatology in the Univ. of Vermont. In one large and handsome 8vo. volume of 835 pages, with 138 illustrations. Cloth, \$4 75; leather, \$5 75; very handsome half Russia, \$6 25.

WELLS ON THE EYE—New Edition—Just Ready.

A TREATISE ON DISEASES OF THE EYE. By J. SOELBERG WELLS, late Professor of Ophthalmology in King's College Hospital. Third American, from the third English edition. Thoroughly revised, with copious notes and additions, by CHARLES S. BULL, M.D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with over 250 engravings on wood and six colored plates, together with selections from the test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, \$5; leather, \$6; half Russia, raised bands, \$6 50.

FOTHERGILL'S HANDBOOK OF TREATMENT—New Edition—Just Ready.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; OR, THE PRINCIPLES OF THERAPEUTICS. By J. MILNER FOTHERGILL, M.D. Edinb., M.R.C.P. Lond., Assist. Physician to the West London Hospital; Assist. Physician to the City of London Hospital, etc. Second edition, revised and enlarged. In one very neat octavo volume of about seven hundred pages. Cloth, \$4; very handsome half Russia, raised bands, \$5 50.

HENRY C. LEA'S SON & CO., Philadelphia.

HENRY C. LEA'S SON & CO.'S
(LATE HENRY C. LEA)
CLASSIFIED CATALOGUE
OF
MEDICAL AND SURGICAL
PUBLICATIONS.

In asking the attention of the profession to the works advertised in the following pages, the publishers would state that no pains are spared to secure a continuance of the confidence earned for the publications of the house by their careful selection and accuracy and finish of execution.

The large number of inquiries received from the profession for a finer class of bindings than is usually placed on medical books has induced us to put certain of our standard publications in half Russia; and, that the growing taste may be encouraged, the prices have been fixed at so small an advance over the cost of sheep as to place it within the means of all to possess a library that shall have attractions as well for the eye as for the mind of the reading practitioner.

The printed prices are those at which books can generally be supplied by booksellers throughout the United States, who can readily procure for their customers any works not kept in stock. Where access to bookstores is not convenient, books will be sent by mail postpaid on receipt of the price, and as the limit of mailable weight has been removed, no difficulty will be experienced in obtaining through the post-office any work in this catalogue. No risks, however, are assumed either on the money or on the books, and no publications but our own are supplied, so that gentlemen will in most cases find it more convenient to deal with the nearest bookseller.

A handsomely illustrated catalogue will be sent to any address on receipt of a three-cent stamp.

HENRY C. LEA'S SON & CO.

Nos. 706 and 708 Sansom St., PHILADELPHIA, August, 1888.

PROSPECTUS FOR 1888.

A NEW WEEKLY MEDICAL JOURNAL.

SUBSCRIPTION RATES.

THE MEDICAL NEWS	Five Dollars.
THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES	Five Dollars.

COMMUTATION RATES.

THE MEDICAL NEWS	} Nine Dollars per annum, in advance.
THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES	

THE MEDICAL NEWS.

**A National Weekly Periodical, of from 28 to 32 Quarto Pages,
containing more Reading Matter
than any other Weekly Medical Journal in America.**

The hearty welcome extended to THE MEDICAL NEWS from all parts of the country is gratifying to all concerned in its publication, since it justifies their belief that the profession felt the need of and would generously support a weekly journal, national in the fullest sense of the word, devoted to the best interests of medical science, and conducted with the forethought to devise and the energy and ability necessary to execute every available plan for enhancing its usefulness. Encouraged by this approbation, those in charge of THE NEWS will make renewed efforts to strengthen in every way its hold upon the respect and esteem of the

profession. Advocating the highest standard of morals and honor, **THE NEWS** will be an unsparing opponent of quackery in its countless forms. As the recognized national organ of the regular profession, it is the chosen vehicle for the conveyance of the most important intelligence from all parts of the country.

The general plan of **THE NEWS** affords ample space for the presentation of articles upon all branches of medical science. The opening pages are devoted to **Original Lectures** by the ablest teachers of the day, which are invariably revised by their authors before publication, thus insuring an authenticity and exactitude otherwise unattainable. In the department of **Original Articles**, **THE NEWS** will endeavor, as heretofore, to surpass its contemporaries in the intrinsic value of its contributions. Under the caption of **Hospital Notes** is laid open the vast and rich store of clinical information developed in the chief hospitals of the globe. The department of **Medical Progress** consists of condensations of articles of importance appearing in the leading medical, pharmaceutical and scientific journals of the world. The **Editorial Articles** are from the pens of a large and able **EDITORIAL BOARD**, and discuss living subjects in all departments of medical science in a thoughtful, independent and scholarly manner. Important subjects, requiring unusually elaborate consideration, are treated in **Special Articles**. The **Proceedings of Societies** in all parts of the country afford a means of imparting valuable information, for which due space is reserved. For the collection of **News Items**, and for **Correspondence**, **THE NEWS** enjoys an organization similar to that of a daily newspaper, and by mail and telegraph receives notice of all professional events of interest through special correspondents, located in the following cities:—In the United States: Portland, Boston, New York, Baltimore, Pittsburgh, Washington, Charleston, New Orleans, Cincinnati, Chicago, Detroit, Kansas City and San Francisco. In Canada: Montreal. In Great Britain: London and Edinburgh. In Continental Europe: Paris, Berlin, Vienna and Florence. In Asia: Yokohama, Canton, Hong Kong and Calcutta. In South America: Rio Janeiro and Valparaiso. In Cuba: Havana. Due attention will be paid to **New Publications**, **New Instruments** and **New Pharmaceutical Preparations**, and a column will be devoted to **Notes and Queries**. Space is reserved each week for accurate reports of all changes in the **Army and Navy Medical Service**.

THE MEDICAL NEWS appears in a double-columned quarto form, printed by the latest improved Hoe speed presses, on handsome paper, from a clear, easily read type, specially cast for its use.

It will thus be seen that **THE MEDICAL NEWS** employs all the approved methods of modern journalism in its efforts to render itself indispensable to the profession; and, in the anticipation of an unprecedented circulation, its subscription has been placed at the exceedingly low rate of \$5 per annum, in advance. At this price it ranks as the cheapest medical periodical in this country, and when taken in connection with **THE AMERICAN JOURNAL** at NINE DOLLARS per annum, it is confidently asserted that a larger amount of material of the highest class is offered than can be obtained elsewhere, even at a much higher price.

THE AMERICAN JOURNAL of the MEDICAL SCIENCES,

Edited by I. MINIS HAYS, A. M., M. D.,

Is published Quarterly, on the first days of January, April, July and October, each Number containing over Three Hundred Octavo Pages, fully Illustrated.

Founded in 1820, **THE AMERICAN JOURNAL** entered with 1883 upon the sixty-fourth consecutive year of faithful and honorable service to the profession. Being the only

periodical in the English language capable of presenting elaborate articles—the form in which the most important discoveries have always been communicated to the profession—**THE AMERICAN JOURNAL** cannot fail to be of the utmost value to physicians who would keep themselves *au courant* with the medical thought of the day. It may justly claim that it numbers among its contributors all the most distinguished members of the profession, that its history is identified with the advances of medical knowledge, and that its circulation is co-extensive with the use of the English language.

During 1883 **THE JOURNAL** will continue to present those features which have long proved so attractive to its readers.

The **Original Department** will consist of elaborate and richly illustrated articles from the pens of the most eminent members of the profession in all parts of the country.

The **Review Department** will maintain its well-earned reputation for discernment and impartiality, and will contain elaborate reviews of new works and topics of the day, and numerous analytical and bibliographical notices by competent writers.

Following these comes the **Quarterly Summary of Improvements and Discoveries in the Medical Sciences**, which, being a classified and arranged condensation of important articles appearing in the chief medical journals of the world, furnishes a compact digest of medical progress abroad and at home.

The subscription price of **THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES** has never been raised during its long career. It is still sent free of postage for Five Dollars per annum in advance.

Taken together, the **JOURNAL** and **NEWS** combine the advantages of the elaborate preparation that can be devoted to a quarterly with the prompt conveyance of intelligence by the weekly; while, by special management, duplication of matter is rendered impossible.

It will thus be seen that for the very moderate sum of NINE DOLLARS in advance the subscriber will receive free of postage a weekly and a quarterly journal, both reflecting the latest advances of the medical sciences, and containing an equivalent of more than 4000 octavo pages, stored with the choicest material, original and selected, that can be furnished by the best medical minds of both hemispheres. It would be impossible to find elsewhere so large an amount of matter of the same value offered at so low a price.

Gentlemen desiring to avail themselves of the advantages thus offered will do well to forward their subscriptions at an early day, in order to insure the receipt of complete sets for 1883.

 The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned; where these are not accessible, remittances for subscriptions may be made at the risk of the publishers by forwarding in *registered* letters.

Address,

HENRY C. LEA'S SON & Co., Nos. 706 and 708 Sansom St., Philadelphia, Pa.

* * * Communications to both these periodicals are invited from gentlemen in all parts of the country. Original articles contributed exclusively to either periodical are liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author.

All letters pertaining to the *Editorial Department* of **THE MEDICAL NEWS** and **THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES** should be addressed to the **EDITORIAL OFFICES**, 1004 Walnut Street, Philadelphia.

All letters pertaining to the *Business Department* of these journals should be addressed *exclusively* to HENRY C. LEA'S SON & Co., 706 and 708 Sansom Street, Philadelphia.

DUNGLISON, ROBLEY, M. D.,*Late Professor of Institutes of Medicine in the Jefferson Medical College of Philadelphia.*

MEDICAL LEXICON; A Dictionary of Medical Science: Containing a concise explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence and Dentistry, Notices of Climate and of Mineral Waters, Formulæ for Official, Empirical and Dietetic Preparations, with the Accentuation and Etymology of the Terms, and the French and other Synonymes, so as to constitute a French as well as an English Medical Lexicon. A new edition, thoroughly revised, and very greatly modified and augmented. By RICHARD J. DUNGLISON, M. D. In one very large and handsome royal octavo volume of 1139 pages. Cloth, \$6.50; leather, raised bands, \$7.50; very handsome half Russia, raised bands, \$8.

The object of the author, from the outset, has not been to make the work a mere lexicon or dictionary of terms, but to afford under each word a condensed view of its various medical relations, and thus to render the work an epitome of the existing condition of medical science. Starting with this view, the immense demand which has existed for the work has enabled him, in repeated revisions, to augment its completeness and usefulness, until at length it has attained the position of a recognized and standard authority wherever the language is spoken. Special pains have been taken in the preparation of the present edition to maintain this enviable reputation. The additions to the vocabulary are more numerous than in any previous revision, and particular attention has been bestowed on the accentuation, which will be found marked on every word. The typographical arrangement has been greatly improved, rendering reference much more easy, and every care has been taken with the mechanical execution. The volume now contains the matter of at least four ordinary octavos.

A book of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Philadelphia Medical Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference.—*Cincinnati Clinic*, Jan. 10, 1874.

As a standard work of reference Dunglison's

work has been well known for about forty years, and needs no words of praise on our part to recommend it to the members of the medical, and likewise of the pharmaceutical, profession. The latter especially are in need of a work which gives ready and reliable information on thousands of subjects and terms which they are liable to encounter in pursuing their daily vocations, but with which they cannot be expected to be familiar. The work before us fully supplies this want.—*American Journal of Pharmacy*, Feb. 1874.

Particular care has been devoted to derivation and accentuation of terms. With regard to the latter, indeed, the present edition may be considered a complete "Pronouncing Dictionary of Medical Science." It is perhaps the most reliable work published for the busy practitioner, as it contains information upon every medical subject, in a form for ready access, and with a brevity as admirable as it is practical.—*Southern Medical Record*, Feb. 1874.

A valuable dictionary of the terms employed in medicine and the allied sciences, and of the relations of the subjects treated under each head. It well deserves the authority and popularity it has obtained.—*British Med. Jour.*, Oct. 31, 1874.

Few works of this class exhibit a grander monument of patient research and of scientific lore.—*London Lancet*, May 13, 1875.

Dunglison's Dictionary is incalculably valuable, and indispensable to every practitioner of medicine, pharmacist and dentist.—*Western Lancet*, March, 1874.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references.—*London Medical Gazette*.

HOBLYN, RICHARD D., M. D.

A Dictionary of the Terms Used in Medicine and the Collateral Sciences. Revised, with numerous additions, by ISAAC HAYS, M. D., late editor of *The American Journal of the Medical Sciences*. In one large royal 12mo. volume of 520 double-columned pages. Cloth, \$1.50; leather, \$2.00.

It is the best book of definitions we have, and ought always to be upon the student's table.—*Southern Medical and Surgical Journal*.

RODWELL, G. F., F. R. A. S., F. C. S.,*Lecturer on Natural Science at Clifton College, England.*

A Dictionary of Science: Comprising Astronomy, Chemistry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magnetism, Mechanics, Meteorology, Pneumatics, Sound and Statics. Contributed by J. T. Bottomley, M. A., F. C. S., William Crookes, F. R. S., F. C. S., Frederick Guthrie, B. A., Ph. D., R. A. Proctor, B. A., F. R. A. S., G. F. Rodwell, Editor, Charles Tomlinson, F. R. S., F. C. S., and Richard Wornell, M. A., B. Sc. Preceded by an Essay on the History of the Physical Sciences. In one handsome octavo volume of 702 pages, with 143 illustrations. Cloth, \$5.00.

HARTSHORNE, HENRY, A. M., M. D.,*Lately Professor of Hygiene in the University of Pennsylvania.*

A Conspectus of the Medical Sciences; Containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practice of Medicine, Surgery and Obstetrics. Second edition, thoroughly revised and greatly improved. In one large royal 12mo. volume of 1028 pages, with 477 illustrations. Cloth, \$4.25; leather, \$5.00.

The work is intended as an aid to the medical student, and as such appears to fulfil admirably its object by its excellent arrangement, the full compilation of facts, the perspicuity and terseness of language, and the clear and instructive illustrations.—*American Journal of Pharmacy*, July, 1874.

The object of this manual is to afford a convenient work of reference to students during the brief moments at their command while in attendance upon medical lectures. It is a favorable sign that it has been found necessary, in a short space of time, to issue a new and carefully revised edition. The illustrations are very numerous and unusually clear, and each part seems to have received

its due share of attention. We can conceive such a work to be useful, not only to students, but to practitioners as well. It reflects credit upon the industry and energy of its able editor.—*Boston Medical and Surgical Journal*, Sept. 3, 1874.

We can say, with the strictest truth, that it is the best work of the kind with which we are acquainted. It embodies in a condensed form all recent contributions to practical medicine, and is therefore useful to every busy practitioner throughout our country, besides being admirably adapted to the use of students of medicine. The book is faithfully and ably executed.—*Charleston Medical Journal*, April, 1875.

STUDENTS' SERIES OF MANUALS.

A Series of Fifteen Manuals, for the use of Students and Practitioners of Medicine and Surgery. They will be written by eminent Teachers or Examiners, and will be issued in pocket-size octavo volumes of 300-500 pages, richly illustrated and at a low price. The following volumes may now be announced: KLEIN'S *Histology* (In a few days), PEP-
PER'S *Surgical Pathology*, TREVES' *Applied Anatomy*, POWER'S *Human Physiology* and RALFE'S *Pathological Chemistry*. (Preparing.)

NEILL, JOHN, M. D., and SMITH, F. G., M. D.,*Late Surgeon to the Penna. Hospital.**Prof. of the Institutes of Med. in the Univ. of Penna.*

An Analytical Compendium of the Various Branches of Medical Science, for the use and examination of Students. A new edition, revised and improved. In one very large royal 12mo. volume of 974 pages, with 374 woodcuts. Cloth, \$4; strongly bound in leather, raised bands, \$4.75.

LUDLOW, J. L., M. D.,*Consulting Physician to the Philadelphia Hospital, etc.*

A Manual of Examinations upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised, and greatly extended and enlarged. In one handsome royal 12mo. volume of 816 large pages, with 370 illustrations. Cloth, \$3.25; leather, \$3.75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

WILSON, ERASMUS, F. R. S.

A System of Human Anatomy, General and Special. Edited by W. H. GOBRECHT, M. D., Professor of General and Surgical Anatomy in the Medical College of Ohio. In one large and handsome octavo volume of 616 pages, with 397 illustrations. Cloth, \$4.00; leather, \$5.00.

SMITH, H. H., M. D., and HORNER, WM. E., M. D.,*Emeritus Prof. of Surgery in the Univ. of Penna., etc.**Late Prof. of Anat. in the Univ. of Penna.*

An Anatomical Atlas, Illustrative of the Structure of the Human Body. In one large imperial octavo volume of 200 pages, with 634 beautiful figures. Cloth, \$4.50.

CLELAND, JOHN, M. D., F. R. S.,*Professor of Anatomy and Physiology in Queen's College, Galway.*

A Directory for the Dissection of the Human Body. In one 12mo. volume of 178 pages. Cloth, \$1.25.

BELLAMY, EDWARD, F. R. C. S.,*Senior Assistant-Surgeon to the Charing-Cross Hospital, London.*

The Student's Guide to Surgical Anatomy: Being a Description of the most Important Surgical Regions of the Human Body, and intended as an Introduction to Operative Surgery. In one 12mo. volume of 300 pages, with 50 illustrations. Cloth, \$2.25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. volume of 310 pages, with 220 woodcuts. Cloth, \$1.75.

SHARPEY AND QUAIN'S HUMAN ANATOMY. Revised by JOSEPH LEIDY, M. D., Prof. of Anat. in Univ. of Penna. In two octavo volumes of about 1300 pages, with 511 illustrations.

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In two octavo volumes of 1007 pages, with 320 woodcuts. Cloth, \$6.00.

HEATH'S PRACTICAL ANATOMY. From second London edition, with additions by W. W. KECK, M. D. In one 12mo. volume of 578 pages, with 247 woodcuts.

ALLEN, HARRISON, M. D.,*Professor of Physiology in the University of Pennsylvania.*

A System of Human Anatomy, Including Its Medical and Surgical Relations. For the use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M. D., Ophthalmologist to the Philadelphia Hospital. In one large and handsome quarto volume of about 600 double-columned pages, with 380 illustrations on 109 lithographic plates, many of which are in colors, and about 250 engravings in the text. In six Sections, each in a portfolio. Section I. HISTOLOGY (*Just Ready*). Section II. BONES AND JOINTS (*Just Ready*). Section III. MUSCLES AND FASCIAE (*Just Ready*). Section IV. ARTERIES, VEINS AND LYMPHATICS (*Just Ready*). Section V. NERVOUS SYSTEM (*Nearly Ready*). Section VI. ORGANS OF SENSE, OF DIGESTION AND GENITO-URINARY ORGANS (*In Press*). Price per Section, \$3.50. For sale by subscription only.

EXTRACT FROM INTRODUCTION.

It is the design of this book to present the facts of human anatomy in the manner best suited to the requirements of the student and the practitioner of medicine. The author believes that such a book is needed, inasmuch as no treatise, as far as he knows, contains, in addition to the text descriptive of the subject, a systematic presentation of such anatomical facts as can be applied to practice.

A book which will be at once accurate in statement and concise in terms; which will be an acceptable expression of the present state of the science of anatomy; which will exclude nothing that can be made applicable to the medical art, and which will thus embrace all of surgical importance, while omitting nothing of value to clinical medicine,—would appear to have an excuse for existence in a country where most surgeons are general practitioners, and where there are few general practitioners who have no interest in surgery.

Among other matters, the book will be found to contain an elaborate description of the tissues; an account of the normal development of the body; a section on the nature and varieties of monstrosities; a section on the method of conducting post-mortem examinations; and a section on the study of the superficies of the body taken as a guide to the position of the deeper structures. These will appear in their appropriate places, duly subordinated to the design of presenting a text essentially anatomical.

A book like this is an ideal rarely realized. It will do, we have no doubt, what its accomplished author hopes: "make anatomy what unfortunately it rarely is—an interesting study." It has long been an opprobrium to America that our anatomical textbooks were all foreign, but this work will remove the stigma. It is a mine of wealth in the information it gives. It differs from all preceding anatomies in its scope, and is, we believe, a vast improvement upon them all. The chief novelty about the book, and really one of the greatest needs in anatomy, is the extension of the text to cover not only anatomical descriptions, but the uses of anatomy in studying disease. This is done by stating the narrower topographical relations, and also the wider clinical relations, of the more remote parts, by giving a brief account of the uses of the various organs, and by quoting cases which illustrate the "localization of diseased action." The plates are beautiful specimens of work by one who long since won a deserved reputation as an artist.—*The Medical News*, October 21, 1882.

The appearance of the book marks an epoch in medical literature. It is the first important work on human anatomy that has appeared in America; and, more than this, its scope is new and original. It is intended to be both descriptive and topographical, scientific and practical, so that while satisfying the anatomist it will be of value to the practising physician. Such a work is certainly novel, and it will bring the greatest honor to the author. The illustrations of the bones are very fine. The names of the parts, muscular attachments, etc., are printed either on the figure or close beside, so that they are easily recognized. Dr. Allen's treatment of the joints is admirable, and the illustrations made from the author's dissections deserve the highest praise. They bear witness to his skill with the scalpel and to that of the artist with his pencil. They are well conceived and well executed, handsome artistically and clear anatomically. As the author points out, such a work as he has undertaken is necessarily encyclopaedic, and the result shows that he has brought to it a mind well prepared for the task by extensive reading, critical judgment and literary ability.

We can cordially recommend the work to the profession, believing that it is suited not only to those of scientific tastes, but that it will be of use to the practising physician.—*Boston Medical and Surgical Journal*, Jan. 11, 1883.

It has fallen to the lot of the fortunate publishers to be able to bring out the best anatomy yet produced in America, and one which will prove much more useful to the general practitioner than the foreign works now accepted as standard. The descriptions are clear, tersely expressed and well up to date. The work, as a whole, shows a great amount of research, and reflects credit upon its author. Its pages teem with well-culled facts which cannot be found in the ordinary anatomical treatises. The lithographic plates are beautifully executed, and deserve unqualified praise. To the more advanced students in anatomy, as well as to the profession at large, it will prove a valuable companion, and one often referred to.—*New York Medical Journal and Obstetrical Review*, Nov. 1882.

It is to be considered a study of applied anatomy in its widest sense—a systematic presentation of such anatomical facts as can be applied to the practice of medicine as well as of surgery. Our author is concise, accurate and practical in his statements, and succeeds admirably in infusing an interest into the study of what is generally considered a dry subject. The department of Histology is treated in a masterly manner, and the ground is travelled over by one thoroughly familiar with it. The illustrations are made with great care, and are simply superb. It would be impossible, except in a general way, to point out the excellence of the work of the author in the second Section—that devoted to the consideration of the Bones and Joints. There is as much of practical application of anatomical points to the every-day wants of the medical clinician as to those of the operating surgeon. In fact, few general practitioners will read the work without a feeling of surprised gratification that so many points, concerning which they may never have thought before, are so well presented for their consideration. It is a work which is destined to be the best of its kind in any language.—*Medical Record*, Nov. 25, '82.

TREVES, FREDERICK, F. R. C. S.,*Senior Demonstrator of Anatomy and Assistant Surgeon at the London Hospital.*

Applied Anatomy. See *Students' Series of Manuals*, page 5.

GRAY, HENRY, F. R. S.,*Lecturer on Anatomy at St. George's Hospital, London.*

Anatomy, Descriptive and Surgical. The Drawings by H. V. CARTER, M. D., and Dr. WESTMACOTT. The dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M. A., Surgeon to St. George's Hospital. Edited by T. Pickering Pick, F. R. C. S., Surgeon and Lecturer on Anatomy at St. George's Hospital, London, Examiner in Anatomy, Royal College of Surgeons of England. A new American from the tenth enlarged and improved London edition. To which is added the second American from the latest English edition of **LANDMARKS, MEDICAL AND SURGICAL**, by LUTHER HOLDEN, F. R. C. S., author of "Human Osteology," "A Manual of Dissections," etc. In one imperial octavo volume of 1020 pages, with 560 large and elaborate engravings on wood. *In a few days.*

The author has endeavored in this work to cover a more extended range of subjects than is customary in the ordinary text-books by giving not only the details necessary for the student, but also the application of those details to the practice of medicine and surgery, thus rendering it both a guide for the learner and an admirable work of reference for the active practitioner. The engravings form a special feature in the work, many of them being the size of nature, nearly all original, and having the names of the various parts printed on the body of the cut, in place of figures of reference with descriptions at the foot. They thus form a complete and splendid series, which will greatly assist the student in forming a clear idea of Anatomy, and will also serve to refresh the memory of those who may find in the exigencies of practice the necessity of recalling the details of the dissecting-room. Combining, as it does, a complete Atlas of Anatomy with a thorough treatise on systematic, descriptive and applied Anatomy, the work will be found of great service to all physicians who receive students in their offices, relieving both preceptor and pupil of much labor in laying the groundwork of a thorough medical education.

Landmarks, Medical and Surgical, by the distinguished Anatomist, Mr. Luther Holden, has been appended to the present edition as it was to the previous one. This work gives in a clear, condensed and systematic way all the information by which the practitioner can determine from the external surface of the body the position of internal parts. Thus complete, the work, it is believed, will furnish all the assistance that can be rendered by type and illustration in anatomical study.

It is difficult to speak in moderate terms of this new edition of "Gray." It seems to be as nearly perfect as it is possible to make a book devoted to any branch of medical science. The addition of Holden's "Landmarks" will make it as indispensable to the practitioner of medicine and sur-

gery as it has been heretofore to the student. As regards completeness, ease of reference, utility, beauty and cheapness, it has no rival. No student should enter a medical school without it; no physician can afford to have it absent from his library.—*St. Louis Clinical Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN, LUTHER, F. R. C. S.,*Surgeon to St. Bartholomew's and the Foundling Hospitals, London.*

Landmarks, Medical and Surgical. Second American from the latest revised English edition, with additions by W. W. KEEN, M. D., Professor of Artistic Anatomy in the Pennsylvania Academy of the Fine Arts, formerly Lecturer on Anatomy in the Philadelphia School of Anatomy. In one handsome 12mo. volume of 148 pages. Cloth, \$1.00.

This little book is all that can be desired within its scope, and its contents will be found simply invaluable to the young surgeon or physician, since they bring before him such data as he requires at every examination of a patient. It is written in language so clear and concise that one ought almost to learn it by heart. It teaches diagnosis by external examination, ocular and palpable, of the body, with such anatomical and physiological facts as directly bear on the subject. It is eminently

the student's and young practitioner's book.—*Physician and Surgeon*, Nov. 1881.

To the student or young surgeon this is practically a most useful little book. We heartily recommend this work to all students and young practitioners, for whom it has been written, and who by its aid will readily be able to make thorough and intelligent examination, or in surgical operations to cut down upon any part with confidence.—*Medical and Surgical Reporter*, Sep. 3, 1881.

DALTON, JOHN C., M. D.,*Professor of Physiology in the College of Physicians and Surgeons, New York.*

The Topographical Anatomy of the Brain. In one very handsome quarto volume of about 200 pages of descriptive text. Illustrated with forty-nine life-size photographic illustrations of Brain Sections, with a like number of outline explanatory plates, as well as many carefully-executed woodcuts through the text. *In press.*

ELLIS, GEORGE VINER,*Emeritus Professor of Anatomy in University College, London.*

Demonstrations of Anatomy. Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the eighth and revised London edition. In one very handsome octavo volume of 716 pages, with 249 illustrations. Cloth, \$4.25; leather, \$5.25.

Ellis' *Demonstrations* is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

DALTON, JOHN C., M. D.,*Professor of Physiology in the College of Physicians and Surgeons, New York, etc.*

A Treatise on Human Physiology. Designed for the use of Students and Practitioners of Medicine. Seventh edition, thoroughly revised and rewritten. In one very handsome octavo volume of 722 pages, with 252 beautiful engravings on wood. Cloth, \$5.00; leather, \$6.00; very handsome half Russia, raised bands, \$6.50.

The reputation which this work has acquired as a compact and convenient summary of the most advanced condition of human physiology renders it only necessary to state that the Author has assiduously labored to render the present edition worthy a continuance of the marked favor accorded to previous issues, and that every care has been bestowed upon the typographical execution to make it, as heretofore, one of the handsomest productions of the American press.

The merits of Professor Dalton's text-book, his smooth and pleasing style, the remarkable clearness of his descriptions, which leave not a chapter obscure, his cautious judgment and the general correctness of his facts, are perfectly known. They have made his text-book the one most familiar to American students.—*Med. Record*, March 4, 1882.

Certainly no physiological work has ever issued from the press that presented its subject-matter in a clearer and more attractive light. Almost every page bears evidence of the exhaustive revision that has taken place. The material is placed in a more compact form, yet its delightful charm is retained, and no subject is thrown into obscurity. Altogether this edition is far in advance of any

previous one, and will tend to keep the profession posted as to the most recent additions to our physiological knowledge.—*Michigan Medical News*, April, 1882.

One can scarcely open a college catalogue that does not have mention of Dalton's *Physiology* as the recommended text or consultation-book. For American students we would unreservedly recommend the edition of Dr. Dalton's work now before us. Let it suffice to state that revisions have been made to such an extent as to bring the volume as fully up to the present state of physiological knowledge as it is practicable for any author of a book to do.—*Virginia Medical Monthly*, July, 1882.

FOSTER, MICHAEL, M. D., F. R. S.,*Professor of Physiology in Cambridge University, England.*

Text-Book of Physiology. Second American from the third English edition. Edited, with extensive notes and additions, by EDWARD T. REICHERT, M. D., late Demonstrator of Experimental Therapeutics in the University of Pennsylvania. In one handsome royal 12mo. volume of 999 pages, with 259 illust. Cloth, \$3.25; leather, \$3.75.

A more compact and scientific work on physiology has never been published, and we believe ourselves not to be mistaken in asserting that it has now been introduced into every medical college in which the English language is spoken. This work conforms to the latest researches into zoology and comparative anatomy, and takes into consideration the late discoveries in physiological chemistry and the experiments in localization of Ferrier and others. The arrangement followed is such as to render the whole subject lucid and well connected in its various parts.—*Chicago Medical Journal and Examiner*, August, 1882.

Dr. Michael Foster's *Manual of Physiology* has been translated into the German, with a preface, by Professor Kühne. Kühne points out in his

preface that the abundant material, in spite of the moderate size, is not condensed to systematic shortness, but the whole is related in a narrative style. Further on he writes: "To give to students and physicians a book which is not intended merely for reference, but which, by its flowing, lively style, invites the reader to go through it, is always useful, especially when the contents, including numerous matters in a state of active discussion in which physiology is now so rich, instruct with truth and calm impartiality. Such the author has preserved throughout." The translation of it into German is a well-merited compliment, since Germany is the especial home of physiology, and its literature is abundantly rich in text-books, monographs and periodicals on physiology.—*American Med. Bi-Weekly*, June 18, 1881.

POWER, HENRY, M. B., F. R. C. S.,*Examiner in Physiology, Royal College of Surgeons of England.*

Human Physiology. See *Students' Series of Manuals*, page, 5.

CARPENTER, WM. B., M. D., F. R. S., F. G. S.; F. L. S.,*Registrar to the University of London, etc.*

Principles of Human Physiology. Edited by HENRY POWER, M. B., Lond., F. R. C. S., Examiner in Natural Sciences, University of Oxford. A new American from the eighth revised and enlarged edition, with notes and additions by FRANCIS G. SMITH, M. D., late Professor of the Institutes of Medicine in the University of Pennsylvania. In one very large and handsome octavo volume of 1083 pages, with two plates and 373 illustrations. Cloth, \$5.50; leather, \$6.50; half Russia, \$7.

The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up fully to the standard of our knowledge of its subject at the present day. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edi-

tion. We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations—a subject that in many respects is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs.—*Jl. of Nerv. and Ment. Dis.*, Apr., '77.

CARPENTER'S PRIZE ESSAY ON THE USE AND ABUSE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. With a preface by D. F. CONDIE, M. D., and explanations of scientific words. In one small 12mo. volume of 178 pages. Cloth, 60 cents.

LEHMANN'S MANUAL OF CHEMICAL PHYS-

IOLOGY. Translated from the German, with notes and additions, by J. CHESTON MORRIS, M. D. In one octavo volume of 327 pages, with 41 illustrations. Cloth, \$2.25.

HARTSHORNE'S ANATOMY AND PHYSIOLOGY. See page 5.

FOWNES, GEORGE, Ph. D.

A Manual of Elementary Chemistry; Theoretical and Practical. Revised and corrected by HENRY WATTS, B. A., F. R. S., Editor of A DICTIONARY OF CHEMISTRY, etc. A new American from the twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M. D. In one large royal 12mo. volume of 1031 pages, with 177 illustrations on wood and a colored plate. Cloth, \$2.75; leather, \$3.25.

The book opens with a treatise on Chemical Physics, including Heat, Light, Magnetism and Electricity. These subjects are treated clearly and briefly, but enough is given to enable the student to comprehend the facts and laws of Chemistry proper. It is the fashion of late years to omit these topics from works on chemistry, but their omission is not to be commended. As was required by the great advance in the science of Chemistry of late years, the chapter on the General Principles of Chemical Philosophy has been entirely rewritten. The latest views on Equivalents, Quantivalence, etc., are clearly and fully set forth. This last edition is a great improvement upon its predecessors, which is saying not a little of a book that has reached its twelfth edition.—*Ohio Medical Recorder*, Oct. 1878.

The student will value the clear and full expositions of *Physical Science*, and the *tubular form* of so

many facts which are thus more readily retained in the memory. The medical practitioner will turn with pleasure to its copious index for the most recent facts in the somewhat hazy and nebulous domain of organic chemistry. In point of fulness the work is a *Modern Dictionary of Chemistry*. In its explanations it is a clear and able treatise, embracing many valuable tables from the standard works of Graham, Miller and Gmelin.—*Canada Medical Record*, Sept. 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former prestige.—*Boston Journal of Chemistry*, Aug. 1878.

ATTFIELD, JOHN, Ph. D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, etc.

Chemistry, General, Medical and Pharmaceutical; Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition, specially revised by the Author. In one handsome royal 12mo. volume of 701 pages, with 87 illustrations. Cloth, \$2.50; leather, \$3.00.

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition. The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*American Journal of Pharmacy*, May, '79.

Each of these editions has been a decided improvement on its predecessor, until now the present edition is as perfect as one could well expect a work of this kind to be. It possesses the advantage over other chemical works intended specially for medical students of being also quite complete as a general chemical textbook. It is even more particularly serviceable to pharmaceutical students and apothecaries, as it includes the whole of the chemistry of the U. S. Pharmacopœia, of the British Pharmacopœia and of the Pharmacopœia of India.—*Union Medical Monitor*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges of the United States. The present edition contains such alterations and additions as seem necessary for the demonstration of the latest developments of chemical principles and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Can. Med. Assoc. J.*, 1879.

The popularity which this work has enjoyed is owing to the original and clear exposition of the facts of the science, the accuracy of its details, and the omission of much which belongs more properly to treatises heavily weighted with unimportant information to the reader. Dr. Attfield writes for students, and primarily for medical students, and always has an eye to the practical application of chemical preparations, and he is successful in bringing the matter in the text into direct connection with the questions which the student is bound to ask.—*Medical and Surgical Reporter*, Apr. 1, '80.

BLOXAM, CHARLES L.

Professor of Chemistry in King's College, London.

Chemistry, Inorganic and Organic. New American from the London edition, thoroughly revised and much improved. In one very handsome volume of about 700 pages, with about 120 illustrations. *In press.*

REMSEN, IRA. M. D., Ph. D.

Professor of Chemistry in the University of Michigan, Ann Arbor.

Principles of Theoretical Chemistry, with special reference to the constitution of Chemical Compounds. New and revised edition. In one handsome volume of about 250 pages. *In press.*

RALFE, CHARLES H., M. D., F. R. C. P.

Professor of Pathology in the University of London.

Pathological Chemistry. Second edition, revised and enlarged.

Wöhler's Outlines of Organic Chemistry. Edited by Ph. D. N. S. D. Professor of Chemistry in the University of Bonn, by IRA REMSEN, M. D., Ph. D., Professor of Physics and Chemistry at Mass. Institute of Technology. 250 pages. Cloth, \$3.

BOWMAN, J. N. & CO., CHEMISTS, 101 N. 3rd St., PHILADELPHIA.

NEW YORK: HENRY C. LEA'S SON & CO., 107 N. 3rd St.

HOFFMANN, F., A.M., Ph.D., & POWER, F.B., Ph.D.,*Public Analyst to the State of New York.**Prof. of Anal. Chem. in Phil. Coll. of Pharmacy.*

A Manual of Chemical Analysis, as applied to the Examination of Medicinal Chemicals and their Preparations. Being a Guide for the Determination of their Identity and Quality, and for the Detection of Impurities and Adulterations. For the use of Pharmacists, Physicians, Druggists and Manufacturing Chemists, and Pharmaceutical and Medical Students. Third edition, entirely rewritten and much enlarged. In one very handsome octavo volume of 621 pages, with 179 illustrations. Cloth, \$4.25. *Just ready.*

The first portion of this work, treating of operations and reagents, and giving a general account of the methods of chemical analysis, has been considerably enlarged and completed, so that now it affords an efficient and explicit guide in the practical execution of chemical analysis. That on volumetric analysis has been correspondingly extended, and a new chapter on the separation and estimation of the alkaloids has been added. The second and main part of the work, containing the physical and chemical characteristics of medicinal chemicals and of the methods of establishing their identity, quality and purity, has been much enlarged and improved, new chemicals of recognized therapeutical value have been added, and new tables and many additional illustrations, introduced. The methods for the quantitative estimation of many chemicals have also received an increased share of attention. Especially is this true in regard to the identification and separation of those of poisonous properties. The labors and results of pharmacopœial revisions both here and in Europe, as well as the kindred literature, have not been neglected; so that the work will be found to correspond with the most recent advances in chemical knowledge.

This excellent work will be at once recognized as a valuable addition to our medical literature. It is important that our druggists and pharmacutists should have facilities at hand to insure themselves of the reliability of the agents they dispense. This work aims to be such a guide, and its publication will be hailed with pleasure by every druggist and practitioner who may desire purity in drugs. We commend a work which affords our pharmacutists and druggists a guide for the analysis of the agents they daily dispense.—*The Buffalo Medical and Surgical Journal*, April, 1883.

Viewed in regard to its general aims as well as

to the manner in which they have been carried out, the work will be found as complete as can well be desired. The descriptions of operations are full without being redundant, so that the tyro can easily understand them and practise the processes successfully; at the same time the details are not given with such minuteness and prolixity as to become wearisome alike to the adept and the student. A work is thus presented well adapted as a book of reference for practical use, and calculated to impart such information as in each particular case may be useful or required within the limit of its objects.—*American Journal of Phar.*, May, 1883.

CLOWES, FRANK, D. Sc., London,*Senior Science-Master at the High School, Newcastle-under-Lyme, etc.*

An Elementary Treatise on Practical Chemistry and Qualitative Inorganic Analysis. Specially adapted for use in the Laboratories of Schools and Colleges and by Beginners. Second American from the third and revised English edition. In one very handsome royal 12mo. volume of 372 pages, with 47 illustrations. Cloth, \$2.50.

The chief object of the author of the present work was to furnish one which was sufficiently elementary in the description of apparatuses, chemicals, modes of experimentation, etc., so as to "reduce to a minimum the amount of assistance required from a teacher." It is a generally recognized fact that one of the most serious hindrances to the utility of many of the smaller text-books is the too great conciseness of the language employed, which

renders it unintelligible to the primary student unless supplemented by copious verbal explanations from the teacher. The *Elementary Treatise* of Dr. Clowes, examined with reference to the above claims, is found to be a great improvement on other elementary works. A student who carefully reads this text will scarcely need the assistance of a tutor in following out any of the experiments described.—*Va. Med. Monthly*, Ap., 1881.

GALLOWAY, ROBERT, F. C. S.,*Professor of Applied Chemistry in the Royal College of Science, Ireland, etc.*

A Manual of Qualitative Analysis. From the sixth London edition. In one handsome royal 12mo. volume, with illustrations. *Preparing.*

CLASSEN, ALEXANDER,*Professor in the Royal Polytechnic School, Aix-la-Chapelle.*

Elementary Quantitative Analysis. Translated, with notes and additions, by EDGAR F. SMITH, Ph. D., Assistant Professor of Chemistry in the Towne Scientific School, University of Pennsylvania. In one handsome royal 12mo. volume of 324 pages, with 36 illustrations. Cloth, \$2.00.

It is probably the best manual of an elementary nature extant, inasmuch as its methods are the best. It teaches by examples, commencing with single determinations, followed by separations,

and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journal of Chemistry*, Oct. 1878.

GREENE, WILLIAM H., M. D.,*Demonstrator of Chemistry in the Medical Department of the University of Pennsylvania.*

A Manual of Medical Chemistry. For the use of Students. Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 310 pages, with 74 illustrations. Cloth, \$1.75.

It is a concise manual of three hundred pages, giving an excellent summary of the best methods of analyzing the liquids and solids of the body, both for the estimation of their normal constituents and

the recognition of compounds due to pathological conditions. The detection of poisons is treated with sufficient fulness for the purpose of the student or practitioner.—*Boston Jl. of Chem.*, June, '80.

PARRISH, EDWARD,

Late Professor of the Theory and Practice of Pharmacy in the Philadelphia College of Pharmacy.

A Treatise on Pharmacy: designed as a Text-book for the Student, and as a Guide for the Physician and Pharmacist. With many Formulas and Prescriptions. Fifth edition, thoroughly revised, by THOMAS S. WIGGAND, Ph. G. In one handsome octavo volume of about 1000 pages, with about 300 illustrations. In press.

A few notices of the previous edition are appended:

Perhaps one of the most important, if not the most important, book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiggand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

We have here an encyclopedia of pharmacy, of

equal value as a text-book for the student and as a guide for the pharmacist and physician, which has reached its fourth edition. A work which has gained such a hold upon the confidence of the profession stands in no need of the recommendation of the press. We have called the treatise an encyclopedia as the name most descriptive of its character—a work in which may be found all that the pharmacist or student of medicine need to know of pharmacy. On whatever point of pharmacy he may be seeking information, he will be fully instructed in this handbook, which is heartily recommended.—*American Practitioner*, July, 1874.

GRIFFITH, R. EGLESFIELD, M. D.

A Universal Formulary; Containing the Methods of Preparing and Administering Official and other Medicines. The whole adapted to Physicians and Pharmacists. Third edition, carefully revised and much enlarged, by JOHN M. MAISCH, Ph. D., Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of 775 pages, with illustrations. Cloth, \$4.50; leather, \$5.50.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to

be committed to memory by every student of medicine. As a help to physicians it will be found invaluable, and doubtless will make its way into libraries not already supplied with a standard work of the kind.—*The American Practitioner*, July, 1874.

HERMANN, Dr. L.,

Professor of Physiology in the University of Zurich.

Experimental Pharmacology. A Handbook of Methods for Determining the Physiological Actions of Drugs. Translated, with the Author's permission, and with extensive additions, by ROBERT MEADE SMITH, M. D., Demonstrator of Physiology in the University of Pennsylvania. In one handsome 12mo. volume of 199 pages, with 32 illustrations. Cloth, \$1.50. Just ready.

TRANSLATOR'S PREFACE.

The translation of Hermann's Manual of Pharmacology was undertaken to furnish the student with a work that would assist him in his studies of the physiological action of drugs, enabling him to make the experiments himself that would otherwise require the assistance of the instructor. The translator has attempted to elucidate the text with a careful selection of illustrations; and he trusts that his additions, which constitute nearly one-half of the entire volume, will render the work a more perfect guide to the student.

The selection of animals and their management, the paths of elimination and changes of poisons in the body, the explanation of the symptoms produced by poisons, alterations in tissue, in the reproductive function and in temperature, action on muscles and in nerves, anatomical and chemical changes produced by poisons, all are successively passed in review in a practical instructive fashion, which speaks well for both the author and the translator. The book is deserving of an encomium as a correct exponent of the spirit and tendencies of modern pharmacological research.

After closely perusing the pages, all laden in overflowing with the richest facts of physiological investigation, and after following the astounding progress of toxic pharmacology as revealed by the author, we feel that we are fast approaching the realization of that utopian dream in which we behold experimental and clinical experience firmly and inseparably united. It is a reliable, concise and practical *read arum* for the time-pressed worker in the laboratory.—*New Orleans Medical and Surgical Journal*, May, 1882.

MAISCH, JOHN M., Ph. D.,

Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy.

A Manual of Organic Materia Medica; Being a Guide to Materia Medica of the Vegetable and Animal Kingdoms. For the use of Students, Druggists, Pharmacists and Physicians. In one handsome royal 12mo. volume of 451 pages, with 194 beautiful illustrations on wood. Cloth, \$2.75.

A book evidently written for a purpose, and not simply for the purpose of writing a book. It is comprehensive, inasmuch as it refers to all, or nearly all, that is of essential value in organic materia medica, clear and simple in its style, concise, since it would be difficult to find in it a superfluous word, and yet sufficiently explicit to satisfy the most critical. The text is freely illustrated with woodcuts, which cannot fail to be valuable in familiarizing students with the physical microscopic and macroscopic appearance of drugs. The work is preceded by a table of contents, and completed with that without which no book should be considered complete, i. e., an index. In fact, the little book is just what it pretends to be, and is worthy

of unqualified commendation.—*Chicago Medical Journal and Examiner*, Aug. 1882.

The above manual, by a well-known authority in this department and one of the authors of the *National Dispensatory*, is a work for which students of pharmacy should be grateful. The subject is one in which the beginner needs the guidance of a good classification in order to avoid the bewilderment which follows the attempt to grasp a subject having so many details. This condition the book fulfils, the classification adopted being a simple and practical one, the notice of each drug is brief and clear, non-essentials being omitted. It is fully illustrated by some two hundred woodcuts.—*Boston Med. and Surg. Journal*, Jan. 26, 1882.

STILLÉ, A., M. D., LL. D., & MAISCH, J. M., Phar. D.,

*Professor of the Theory and Practice of
Medicine and of Clinical Medicine in the
University of Pennsylvania.*

*Prof of Mat. Med. and Botany in Phila.
College of Pharmacy, Sec'y to the Ameri-
can Pharmaceutical Association.*

The National Dispensatory: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain and Germany, with numerous references to the French Codex. Third edition, thoroughly revised and greatly enlarged. In one magnificent imperial octavo volume of about 1600 pages, with several hundred fine engravings. *In press.*

The publishers have much pleasure in announcing to the Medical and Pharmaceutical Professions that a new edition of this important work is in press, and that it will appear in the shortest time consistent with the care requisite for printing a work of immense detail, where absolute accuracy is of such supreme importance. Besides its revision on the basis of the U. S. Pharmacopœia of 1880, it will include all the advances made in its department during the period elapsed since the preparation of that work. To this end all recent medical and pharmaceutical literature, both domestic and foreign, has been thoroughly sifted, and everything that is new and important has been introduced, together with the results of original investigations. To accord with the new Pharmacopœia the officinal formulæ are given in parts by weight, but in every instance, for the sake of convenience, the same proportions are also expressed in ordinary weights and measures. The Therapeutical Index has been enlarged so that it contains about 8000 references, arranged under an alphabetical list of diseases, thus placing at the disposal of the practitioner, in the most convenient manner, the vast stores of therapeutical knowledge constantly needed in his daily practice. The work may therefore be justly regarded as a complete Encyclopædia of Materia Medica and Therapeutics up to 1883.

The exhaustion of two very large editions of THE NATIONAL DISPENSATORY since 1879 is the most conclusive testimony as to the necessity which demanded its preparation and to the admirable manner in which that duty has been performed. In this revision the authors have sought to add to its usefulness by including everything properly coming within its scope which can be of use to the physician or pharmacist and at the same time by the utmost conciseness and by the omission of all obsolete matter to prevent undue increase in the size of the volume. No care will be spared by the publishers to render its typographical execution worthy of its wide reputation and universal use as the standard authority.

A few notices of the previous edition are appended.

The authors have embraced the opportunity offered for a thorough revision of the whole work, striving to include within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration and the short interval elapsed since the previous publication. After having gone carefully through the volume, we must admit that the authors have labored faithfully and with success in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica and Therapeutics. —*Am. Jour. of Pharmacy*, Nov. 1879.

The authors have produced a work which for accuracy and comprehensiveness is unsurpassed by any work on the subject. There is no book in the English language which contains so much

valuable information on the various articles of the materia medica. *Edinburgh Med. Jour.*, Nov. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained if desired. Its value is greatly enhanced by the extensive indexes—a general index of materia medica, etc., and also an index of therapeutics. No practising physician can afford to be without The National Dispensatory. —*Canada Med. and Surg. Journ.*, Feb. 1880.

A kind of international codex, available to the English-speaking community of all nations; emphatically, we would repeat, a book for the practitioner—one well calculated to give him hints as to treatment and most suggestive as to remedies. —*London Medical Times and Gazette*.

BRUNTON, T. LAUDER, M. D.,

Lecturer on Materia Medica and Therapeutics at St. Bartholomew's Hospital, etc.

A Manual of Materia Medica and Therapeutics, including the Pharmacy, the Physiological Action and the Therapeutical Uses of Drugs. In one handsome octavo volume. *In press.*

STILLÉ, ALFRED, M. D., LL. D.,

Professor of Theory and Practice of Med. and of Clinical Med. in the Univ. of Penna.

Therapeutics and Materia Medica. A Systematic Treatise on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome octavo volumes, containing 1936 pages. Cloth, \$10.00; leather, \$12.00; very handsome half Russia, raised bands, \$13.00.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict. —*American Journal of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in the

multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question. —*Boston Medical and Surgical Journal*, Nov. 5, 1874.

FARQUHARSON, ROBERT, M. D.,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A Guide to Therapeutics and Materia Medica. Third American edition, specially revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia by FRANK WOODBURY, M. D. In one very handsome 12mo. volume of 524 pages. Cloth, \$2.25. *Just ready.*

Dr. Farquharson's Therapeutics is constructed upon a plan which brings before the reader all the essential points with reference to the properties of drugs. It impresses these upon him in such a way as to enable him to take a clear view of the actions of medicines and the disordered conditions in which they must prove useful. The double-columned pages—one side containing the recognized physiological action of the medicine, and the other the disease in which observers (who are nearly always mentioned) have obtained from it good results—make a very good arrangement. The early chapter containing rules for prescribing is excellent. We have much pleasure in once more drawing attention to this valuable and well-digested

book, and predict for it a continued successful career.—*Canada Med. and Surg. Journal*, Dec. 1882.

This is the best student's materia medica that we have ever seen. The pages are double-columned, one column being for the physiological action, the other for the therapeutic use; in this way the student can study the two together. It also contains a list of poisons and their chemical and physiological antidotes, and a very complete table of the metric weights and their equivalents. Though we can recommend it so highly to students, it would be a very useful addition to the practitioner's library. There are two indexes, one of therapeutic agents, the other of diseases.—*Virginia Medical Monthly*, March, 1883.

GREEN, T. HENRY, M. D.,

Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, etc.

Pathology and Morbid Anatomy. Fifth American from the sixth enlarged and revised English edition. In one very handsome octavo volume of about 350 pages, with about 150 fine engravings. *Preparing.*

COATS, JOSEPH, M. D., F. F. P. S.,

Pathologist to the Glasgow Western Infirmary.

A Treatise on Pathology. In one very handsome octavo volume of about 900 pages, with 339 beautiful illustrations. *Nearly ready.*

Within the limits of a single volume the Author has endeavored to present a complete text-book of General Pathology and Pathological Anatomy—two departments of a single science which, to the great inconvenience of students, it has hitherto been the custom to treat independently. Beginning with a thorough exposition of the various processes of disease in their essential nature, the Author proceeds to consider the alterations these processes cause and undergo when acting in special regions or organs. Throughout the work much space is devoted to Clinical Pathology. While the Author has availed himself of all the literature of the subject, including Ziegler's recent work, he has mainly relied upon his long experience as a pathologist and teacher for the matter here gathered and for the manner of its presentation.

CORNIL, V., and RANVIER, L.,

Prof. in the Faculty of Med. of Paris.

Prof. in the College of France.

A Manual of Pathological Histology. Translated, with notes and additions, by E. O. SHAKESPEARE, M. D., Pathologist and Ophthalmic Surgeon to Philadelphia Hospital, and by J. HENRY C. SIMES, M. D., Demonstrator of Pathological Histology in the University of Pennsylvania. In one very handsome octavo volume of 800 pages, with 360 illustrations. Cloth, \$5.50; leather, \$6.50; half Russia, raised bands, \$7.

We have no hesitation in cordially recommending the translation of Cornil and Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*American Journal of the Medical Sciences*, April, 1880.

One of the most complete volumes on pathological histology we have ever seen. The plan of study

embraced within its pages is essentially practical. Normal tissues are discussed, and after their thorough demonstration we are able to compare any pathological change which has occurred in them. Thus side by side physiological and pathological anatomy go hand in hand, affording that best of all processes in demonstrations, comparison. The admirable arrangement of the work affords facility in the study of any part of the human economy.—*New Orleans Medical and Surgical Journal*, June, 1882.

KLEIN, E., M. D., F. R. S.,

Joint Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, London.

Elements of Histology. In one handsome 12mo. volume of about 350 pages with 181 illustrations. *Shortly.* (See *Students' Series of Manuals*, page 5.)

SCHÄFER, EDWARD ALBERT, M. D.,

Assistant Professor of Physiology in University College, London.

A Course of Practical Histology. Being an introduction to the use of the Microscope. In one handsome royal 12mo. volume of 308 pages, with 40 illustrations. Cloth, \$2.00.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with notes and additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures,

plain and colored, and descriptive letter-press. Cloth, \$4.00.

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. See page 5.

FLINT, AUSTIN, M. D.,*Prof. of the Principles and Practice of Med. and of Clin. Med. in Bellevue Hospital Medical College.*

A Treatise on the Principles and Practice of Medicine. Designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely-printed octavo volume of 1150 pages. \$5.50; leather, \$6.50; very handsome half Russia, raised bands, \$7.

We cannot conclude this notice without expressing our admiration for this volume, which is certainly one of the standard text-books on medicine; and we may safely affirm that, taken altogether, it exhibits a fuller and wider acquaintance with recent pathological inquiry than any similar work with which we are acquainted, whilst at the same time it shows its author to be possessed of the rare faculties of clear exposition, thoughtful discrimination and sound judgment.—*London Lancet*, July 23, 1881.

In a word, we do not know of any similar work which is at once so elaborate and so concise, so full and yet so accurate, or which in every part leaves upon the mind the impression of its being the product of an author richly stored with the fruits of clinical observation, and an adept in the art of conveying them clearly and attractively to others.—*American Journal of Medical Sciences*, April, 1881.

Flint's Treatise is the work of an accomplished hospital physician, and is remarkable for its masterly descriptions of disease. It is a work on clinical medicine embodying the experience of a lifetime. It has been carefully brought up to the present day, and the additions and alterations have been so great that it is virtually a new work, and

not merely a new edition. In making these additions, Flint openly confesses that he has not been too careful to maintain a character for consistency, but has endeavored to give his reader his own matured, and, as he believes, more truthful views, careless of any discrepancy between the views of those he formerly advanced. Flint is right in this way could he produce a work worth being looked upon as a standard.—*Edinburgh Medical Journal*, June, 1882.

This work is so widely known and accepted as the best American text-book of the practice of medicine that it would seem hardly worth while to give this, the fifth edition, anything more than a passing notice. But even the most cursory examination shows that it is, practically, much more than a revised edition; it is, in fact, rather a new work throughout. This treatise will undoubtedly continue to hold the first place in the estimation of American physicians and students. No other of our medical writers approaches Professor Flint in clearness of diction, breadth of view, and, in the regard of transcendent importance, rationality, and estimate of the value of remedial agents. It is not only thoroughly practical, therefore pre-eminently adapted for American readers.—*St. Louis Clin. Rec.*, March, 1882.

HARTSHORNE, HENRY, M. D.,*Late Professor of Hygiene in the University of Pennsylvania.*

Essentials of the Principles and Practice of Medicine. A Handbook for Students and Practitioners. Fifth edition, thoroughly revised and rewritten. In one handsome royal 12mo. volume of 669 pages, with 144 illustrations. Cloth, \$2.75; bound, \$3.00. *Just ready.*

The author of this book seems to have spared no pains to bring it up to the modern standpoint, for as we turn over its pages we find many subjects introduced which have only lately been brought before the profession. Certainly amongst books of its class it deserves and has obtained a good position. On the whole it is a careful and conscientious piece of work, and may be commended.—*London Lancet*, June 24, 1882.

Within the compass of 600 pages it treats of the history of medicine, general pathology, general symptomatology, and physical diagnosis (including laryngoscope, ophthalmoscope, etc.), general therapeutics, nosology, and special pathology and practice. With such a wide range, condensation is, of course, a necessity; but the author has endeavored to make up for this by copious references to original

papers, etc. We cannot but admit that the wonderful amount of information contained in this work, and that it is one of the best of its kind we have seen.—*Glasgow Medical Journal*, Nov., 1882.

An indispensable book. No work ever existed which gave a better average of actual practical treatment than this one; and probably not one writer in our country had a better opportunity than Dr. Hartshorne of condensing all the views of eminent practitioners into a 12mo. The numerous illustrations are very useful to students especially. These Essentials, as the name suggests, are not intended to supersede the text-books of Flint and Barlow, but they are the most valuable in affording a means to see at a glance the whole literature of disease, and the most valuable treatment.—*Medical Journal and Examiner*, April, 1882.

WOODBURY, FRANK, M. D.,*Physician to the German Hospital, Philadelphia; late Chief Assistant to the Medical Clinic in Jefferson College Hospital, etc.*

A Handbook of the Principles and Practice of Medicine. For the use of Students and Practitioners. In one royal 12mo. volume, with illustrations. *In preparation.*

BRISTOWE, JOHN SYER, M. D., F. R. C. P.,*Physician and Joint Lecturer on Medicine at St. Thomas' Hospital.*

A Treatise on the Practice of Medicine. Second American edition, revised by the Author. Edited, with additions, by JAMES H. HUTCHINSON, M.D., physician to the Pennsylvania Hospital. In one handsome octavo volume of 1085 pages, with illustrations. Cloth, \$5.00; leather, \$6.00; very handsome half Russia, raised bands, \$6.50.

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the latest growth of medical science.—*Boston Medical and Surgical Journal*, Feb., 1880.

His accuracy in the portraiture of disease, his care in stating subtle points of diagnosis, and the

faithfully given pathology of abnormal processes have seldom been surpassed. He embraces diseases not usually considered to belong to the domain of medicine, and practice, as skin diseases, syphilis and its complications, but they will not be objected to by readers, as he has studied them conscientiously and drawn from his own life.—*Medical and Surgical Reporter*, Dec. 20, 1880.

The reader will find every conceivable point connected with the practice of medicine and surgery presented, in a style at once clear, interesting and concise. The additions made by Dr. Hutchinson are appropriate and practical, and greatly increase its usefulness to American readers.—*Buffalo Medical and Surgical Journal*, March, 1880.

REYNOLDS, J. RUSSELL, M. D.,*Professor of the Principles and Practice of Medicine in University College, London.*

A System of Medicine. With notes and additions by HENRY HARTSHORNE, A. M., M. D., late Professor of Hygiene in the University of Pennsylvania. In three large and handsome octavo volumes, containing 3056 double-columned pages, with 317 illustrations. Price per volume, cloth, \$5.00; sheep, \$6.00; very handsome half Russia, raised bands, \$6.50. Per set, cloth, \$15; sheep, \$18; half Russia, \$19.50. *Sold only by subscription.*

VOLUME I. Contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.

VOLUME II. Contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.

VOLUME III. Contains DISEASES OF THE DIGESTIVE, BLOOD-GLANDULAR, URINARY, REPRODUCTIVE and CUTANEOUS SYSTEMS.

Reynolds' SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as, for instance, diseases of the bladder by Sir Henry Thompson, malposition of the uterus by Graily Hewitt, insanity by Henry Maudsley, consumption by J. Hughes Bennet, diseases of the spine by Charles Bland Radcliffe, pericarditis by Francis Sibson, alcoholism by Francis E. Anstie, renal affections by William Roberts, asthma by Hyde Salter, cerebral affections by H. Charlton Bastian, gout and rheumatism by Alfred Baring Garrod, constitutional syphilis by Jonathan Hutchinson, diseases of the stomach by Wilson Fox, diseases of the skin by Balmanno Squire, affections of the larynx by Morell Mackenzie, diseases of the rectum by Blizard Curling, diabetes by Lauder Brunton, intestinal diseases by John Syer Bristowe, catalepsy and somnambulism by Thomas King Chambers, apoplexy by J. Hughlings Jackson, angina pectoris by Professor Gairdner, emphysema of the lungs by Sir William Jenner, etc., etc. All the leading schools in Great Britain have contributed their best men, in generous rivalry, to build up this monument of medical science. That a work conceived in such a spirit and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable; and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have, by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions were required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by HENRY HARTSHORNE, M. D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us, than "Reynolds' System of Medicine." It contains just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*American Journal of the Medical Sciences*, Jan. 1880.

Certainly no work with which we are acquainted has ever been given to the English-reading profession which treats of so many diseases in a manner so concise and thorough, and withal so lucid and trustworthy. In that branch of medicine in which the rank and file of the profession are mainly interested, viz., the practical part, therapeutics, Reynolds, without intending any invidious comparison, stands pre-eminent. The therapeutics of the English correspond more closely than those of any other country with those of this country, and the American editor of Reynolds' has brought this branch up to the most advanced American standard.—*Michigan Medical News*, Feb. 15, 1880.

WATSON, THOMAS, M. D.,*Late Physician in Ordinary to the Queen.*

Lectures on the Principles and Practice of Physic. Delivered at King's College, London. A new American from the fifth English edition, revised and enlarged. Edited, with additions, and 190 illustrations, by HENRY HARTSHORNE, A. M., M. D., late Professor of Hygiene in the University of Pennsylvania. In two large and handsome octavo volumes, containing 1840 pages. Cloth, \$9.00; leather, \$11.00.

FOTHERGILL, J. M., M. D., Edin., M. R. C. P., Lon*Asst. Phys. to the West Lond. Hosp., Asst. Phys. to the City of Lond. Hosp., etc.*

The Practitioner's Handbook of Treatment; Or, The Principles of Therapeutics. Second edition, revised and enlarged. In one very handsome octavo volume of 600 pages. Cloth, \$4.00; very handsome half Russia, raised bands, \$5.50.

A book which can give correctly and interestingly, as well as scientifically, the method of prescribing and the rationale of the best therapeutics in the treatment of disease, is manifestly just the work which each physician desires. It is not extravagant eulogy to say that the physician will find in this work of Fothergill the guide which he seeks for his therapeutics; for not only is the treatment which he seeks already indicated herein, but the rationale of the treatment is as clearly explained.—*Gaillard's Med. Journ.*, Sept. 1880.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the

impress of a master-hand; and while the work is thoroughly scientific in every particular, it presents to the thoughtful reader all the charms and ties of a well-written novel. No physician can well afford to be without this valuable work, the originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journ. of Med. Surg.*, Oct. 1880.

The junior members of the profession will find it a work that should not only be read but fully studied. It will assist them in the selection and combination of therapeutical measures best adapted to each case and condition, and enable them to prescribe intelligently and successfully.—*St. Louis Courier of Medicine*, Nov. 1880.

FLINT, AUSTIN, M. D.

Clinical Medicine. A Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 799 pages. Cloth, \$4.50; leather, \$5.50; half Russia, \$6.00.

It is here that the skill and learning of the great clinician are displayed. He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879.

To give an adequate and useful conspectus of the extensive field of modern clinical medicine is a task of no ordinary difficulty; but to accomplish this consistently with brevity and clearness, the different subjects and their several parts receiving the attention which, relatively to their importance, medical opinion claims for them, is still more difficult. This task, we feel bound to say, has been executed with more than partial success by Dr. Flint, whose name is already familiar to students

of advanced medicine in this country as the author of two works of great merit on similar subjects, and of numerous papers exhibiting originality and extensive research.—*The Medical Journal*, Dec. 1879.

The great object is to place before the reader the latest observations and experience in diagnosis and treatment. Such a work is especially valuable to students. It is complete in its special department and yet so condensed that they can by its aid keep up with the lectures on practice without neglecting other branches. It will not escape the notice of the practitioner that such a work is most valuable in culling points in diagnosis and treatment in the intervals between the daily rounds of the hospital, since he can in a few minutes refresh his memory or learn the latest advance in the treatment of diseases which demand his instant attention.—*Cincinnati Lancet and Clinic*, Oct. 25, 1879.

By the Same Author.

Essays on Conservative Medicine and Kindred Topics. In one very handsome royal 12mo. volume of 210 pages. Cloth, \$1.38.

FINLAYSON, JAMES, M. D.,*Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.*

Clinical Diagnosis. A Handbook for Students and Practitioners of Medicine. In one handsome 12mo. volume of 546 pages, with 85 illustrations. Cloth, \$2.63.

The book is an excellent one—clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan 4, 1879.

This is one of the really useful books. It is at-

tractive from preface to the final page, and to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes; and because of its arrangement and complete index it is unusually convenient for quick reference in any emergency that may arise upon the busy practitioner.—*N. C. Med. J.*, Jan. 1879.

FENWICK, SAMUEL, M. D.,*Assistant Physician to the London Hospital.*

The Student's Guide to Medical Diagnosis. From the third revised and enlarged English edition. In one very handsome royal 12mo. volume of 328 pages, with 87 illustrations on wood. Cloth, \$2.25.

TANNER, THOMAS HAWKES, M. D.

A Manual of Clinical Medicine and Physical Diagnosis. Third American edition, from the second London edition. Revised and enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, London, etc. In one handsome 12mo. volume of 362 pages, with illustrations. Cloth, \$1.50.

STURGES' INTRODUCTION TO THE STUDY OF CLINICAL MEDICINE. Being a Guide to the Investigation of Disease. In one handsome 12mo. volume of 127 pages. Cloth, \$1.25.

DAVIS' CLINICAL LECTURES ON VARIOUS

IMPORTANT DISEASES; being a collection of the Clinical Lectures delivered in the Medical Ward of Mercy Hospital, Chicago. Edited by FRANK H. DAVIS, M. D. Second edition. In one royal 12mo. volume of 287 pages. Cloth, \$1.00.

BARTHOLOW, ROBERTS, A. M., M. D., LL. D.,

Prof. of Materia Medica and General Therapeutics in the Jefferson Med. Coll. of Phila., etc.

A Practical Treatise on the Applications of Electricity to Medicine and Surgery. Second edition. In one very handsome octavo volume of 292 pages, with 109 illustrations. Cloth, \$2.50. *Just ready.*

FROM THE PREFACE TO THE SECOND EDITION.

In the present edition I have made many additions and improvements to render the work more useful to those for whom it is intended. In response to what seems to me an increasing desire for scientific treatment, I have developed more fully the modern methods of ascertaining and expressing current strength, tension, resistance, etc. I have also entered more fully into the polar method, and into the action and uses of the magnet. Thus improved, I hope that the new edition will continue to enjoy the favor so largely bestowed on the first.

The second edition of this work following so soon upon the first would in itself appear to be a sufficient announcement; nevertheless, the text has been so considerably revised and condensed, and so much enlarged by the addition of new matter, that we cannot fail to recognize a vast improvement upon the former work. The author has prepared his work for students and practitioners—for those who have never acquainted themselves with the subject, or, having done so, find that after a time their knowledge needs refreshing. We think he has accomplished this object. The book is not too voluminous, but is thoroughly practical, simple, complete and comprehensible. It is, moreover, replete with numerous illustrations of instruments, appliances, etc.—*Med. Record*, Nov. 15, 1882.

It is, fortunately, not such an interminable treatise as most electro-therapeutists like to write. It is not burdened with a needlessly learned terminology, and is written more from the point of view of the physician than of the specialist. The second edition has been considerably increased over the

first, and has been brought up to the most recent advances of the science. It can in every way be recommended to those who wish to read a lucid, manageable monograph on this form of therapeutics.—*Med. and Surg. Reporter*, Nov. 4, 1882.

A most excellent work, addressed by a practitioner to his fellow-practitioners, and therefore thoroughly practical. The work now before us has the exceptional merit of clearly pointing out where the benefits to be derived from electricity must come. It contains all and everything that the practitioner needs in order to understand intelligently the nature and laws of the agent he is making use of, and for its proper application in practice. In a condensed, practical form, it presents to the physician all that he would wish to remember after perusing a whole library on medical electricity, including the results of the latest investigations. It is the book for the practitioner, and the necessity for a second edition proves that it has been appreciated by the profession.—*Physician and Surgeon*, Dec. 1882.

RICHARDSON, B. W., M. A., M. D., LL. D., F. R. S., F. S. A.

Fellow of the Royal College of Physicians, London.

Preventive Medicine. In one octavo volume of about 500 pages. *In press.*

The immense strides taken by medical science during the last quarter of a century have had no more conspicuous field of progress than the causation of disease. Not only has this led to marked advance in therapeutics, but it has given rise to a virtually new department of medicine—the prevention of disease—more important, perhaps, in its ultimate results than even the investigation of curative processes. Yet thus far there has been no attempt to gather into a systematic and intelligible shape the accumulation of knowledge acquired on this most interesting subject. Fortunately, the task has been at last undertaken by a writer who of all is perhaps best qualified for its performance, and the result of his labors can hardly fail to mark an epoch in the history of medical science. The plan adopted for the execution of his novel design can best be explained in his own words:

"I have nothing to say in this volume that has any relation to the cure of disease, but I base it nevertheless on the curative side of medical learning. In other words, I trace the diseases from their actual representation as they exist before us, in their natural progress after their birth, as far as I am able, back to their origins, and try to seek the conditions out of which they spring. Thereupon I endeavor further to analyze those conditions, to see how far they are removable and how far they are avoidable."

HABERSHON, S. O., M. D.,

Senior Physician to and late Lect. on Principles and Practice of Med. at Guy's Hospital, London.

On the Diseases of the Abdomen; Comprising those of the Stomach, and other parts of the Alimentary Canal, Oesophagus, Cæcum, Intestines and Peritoneum. Second American from third enlarged and revised English edition. In one handsome octavo volume of 554 pages, with illustrations. Cloth, \$3.50.

This valuable treatise will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapters have been added, bringing the work fully up to

the times, and making it a volume of interest to the practitioner in every field of medicine and surgery. Perverted nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr. Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Medical Journal*, April, 1879.

A CENTURY OF AMERICAN MEDICINE, 1776—1876. By Drs. E. H. CLARKE, H. J. BIGELOW, S. D. GROSS, T. G. THOMAS, and J. S. BILLINGS. In one 12mo. volume of 370 pages. Cloth, \$2.25.

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With additions by D. F. CONDIE, M. D. 1 vol. 8vo., pp. 603. Cloth, \$2.50.

TODD'S CLINICAL LECTURES ON CERTAIN

ACUTE DISEASES. In one octavo volume of 320 pages. Cloth, \$2.50.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol. 8vo., pp. 493. Cloth, \$3.50.

SEILER, CARL, M. D.,*Lecturer on Laryngoscopy in the University of Pennsylvania.*

A Handbook of Diagnosis and Treatment of Diseases of the Throat, Nose and Naso-Pharynx. Second edition. In one handsome royal 12mo. volume of 294 pages, with 77 illustrations. Cloth, \$1.75. *Just ready.*

The work before us is a concise hand-book upon the essentials of diagnosis and treatment in diseases of the throat and nose. The art of laryngoscopy, the anatomy of the throat and nose and the pathology of the mucous membrane are discussed with conciseness and ability. The work is profusely illustrated, excels in many essential features,

and deserves a place in the office of the practitioner who would inform himself as to the nature, diagnosis and treatment of a class of diseases almost inseparable from general medical practice. With advanced students the book must be very popular on account of its condensed style.—*Louisville Medical News*, June 26, 1883.

BROWNE, LENNOX, F. R. C. S., Edin.,*Senior Surgeon to the Central London Throat and Ear Hospital, etc.*

The Throat and its Diseases. Second American from the second English edition, thoroughly revised. With 100 typical illustrations in colors and 50 wood engravings, designed and executed by the Author. In one very handsome imperial octavo volume of about 350 pages. *Preparing.*

FLINT, AUSTIN, M. D.,*Professor of the Principles and Practice of Medicine in Bellevue Hospital Medical College, N. Y.*

A Manual of Auscultation and Percussion; Of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. Third edition. In one handsome royal 12mo. volume of 240 pages. Cloth, \$1.63. *Just ready.*

This practical and justly popular manual is conveniently divided into eight chapters, and the student is gradually led up from a general consideration of physical signs in health and disease to the differential diagnosis of diseased conditions by a knowledge of these physical signs. As in his courses of practical instruction, so in this book the author's plan is to simplify the subject as much as possible; to consider the distinguishing characteristics of different physical signs as de-

termined by analysis, and as based particularly on the variations in the intensity, pitch and quality of sounds; to impress the facts upon the student and reader that the significance of physical signs relates to certain physical conditions, and that close study of the physical conditions in health and disease is a *sine qua non* of success in both diagnosis and treatment.—*The Medical News*, April 28, 1883.

By the Same Author.

Physical Exploration of the Lungs by Means of Auscultation and Percussion. Three lectures delivered before the Philadelphia County Medical Society, 1882-83. In one handsome small 12mo. volume of 83 pages. Cloth, \$1.00. *Just ready.*

By the Same Author.

A Practical Treatise on the Physical Exploration of the Chest and the Diagnosis of Diseases Affecting the Respiratory Organs. Second and revised edition. In one handsome octavo volume of 591 pages. Cloth, \$4.50.

By the Same Author.

Phthisis: Its Morbid Anatomy, Etiology, Symptomatic Events and Complications, Fatality and Prognosis, Treatment and Physical Diagnosis; In a series of Clinical Studies. In one handsome octavo volume of 442 pages. Cloth, \$3.50.

By the Same Author.

A Practical Treatise on the Diagnosis, Pathology and Treatment of Diseases of the Heart. Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate. Cloth, \$4.

GROSS, S. D., M.D., LL.D., D.C.L. Oxon., LL.D. Cantab.

A Practical Treatise on Foreign Bodies in the Air-passages. In one octavo volume of 452 pages, with 59 illustrations. Cloth, \$2.75.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms and Treatment. From the second and revised English edition. In one octavo volume of 475 pages. Cloth, \$3.50.

SLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries. Second and revised edition. In one 12mo. vol., pp. 158. Cloth, \$1.25.

WILLIAMS ON PULMONARY CONSUMPTION; its Nature, Varieties and Treatment. With an analysis of one thousand cases to exemplify its duration. In one 8vo. vol. of 303 pp. Cloth, \$2.50.

SMITH ON CONSUMPTION; its Early and Remediable Stages. 1 vol. 8vo., pp. 253. \$2.25.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo. of 490 pages. Cloth, \$3.00.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American edition. In 1 vol. 8vo., 416 pp. Cloth, \$3.00.

STOKES' LECTURES ON FEVER. Edited by John William Moore, M. D., F. K. Q. C. P. In one octavo volume of 280 pages. Cloth, \$2.00.

A TREATISE ON FEVER. By ROBERT D. LYONS, K. C. C. In one 8vo. vol. of 354 pp. Cloth, \$2.25.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M. D., M. R. I. A. In one octavo volume of 308 pages. Cloth, \$2.50.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological and Therapeutical Relations. In two large and handsome octavo volumes of 1468 pp. Cloth, \$7.00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION; its Disorders and their Treatment. From the second London edition. In one octavo volume of 238 pages. Cloth, \$2.00.

CHAMBERS' MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume of 302 pp. Cloth, \$2.75.

HAMILTON, ALLAN McLANE, M. D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N. Y., and at the Out-Patients' Department of the New York Hospital.

Nervous Diseases; Their Description and Treatment. Second edition, thoroughly revised and rewritten. In one handsome octavo volume of 598 pages, with 72 illustrations. Cloth, \$4.

We are glad to welcome a second edition of so useful a work as this, in which Dr. Hamilton has succeeded in condensing into convenient limits the most important of the recent developments in regard to diseases of the nervous system. Of recent years nervous pathology has attained to such importance as to necessitate very careful description in special works, and among these this volume must take a high place. This volume is on the whole excellent, and is devoid of that spirit of plagiarism which we have unfortunately seen too much of in certain recent English works on nervous diseases.—*Edinburgh Medical Journal*, May, 1882.

When the first edition of this good book appeared we gave it our emphatic endorsement, and the present edition enhances our appreciation of the book and its author as a safe guide to students of clinical neurology. One of the best and most critical of English neurological journals, *Brain*, has characterized this book as the best of its kind in any language, which is a handsome endorsement from an exalted source. The improvements in the new edition, and the additions to it, will justify its purchase even by those who possess the old.—*Alienist and Neurologist*, April, 1882.

The book is made up of plain and practical descriptions of the chief disorders of the nervous system, with interesting discussions of pathological points and very sensible views as to treatment. It is a book which the general practitioner will find of great value.—*N. Y. Med. Jour.*, Sept. 1882.

The author's aim is to write a treatise on Nervous Diseases which is both concise and practical, while it is, at the same time, sufficiently comprehensive. We have pleasure in bearing testimony to the fact that his efforts have been crowned with success. The various diseases have been well described, the directions as to how to arrive at a correct diagnosis are very clear, and the hints in treatment are plain, practical and sound. Such a book should be considered a necessity in every medical library, as the ailments described are among the most common that come under observation in the everyday work of the general physician. To him, therefore, we recommend it with pleasure; in fact, we may go further and say that, all things considered, it is for his purpose the best work of the kind now available.—*Canada Jour. Med. Sciences*, April, 1882.

This work is well adapted to the wants of the general practitioner, for whom it seems to have been especially written. It is a thoroughly practical book, the careful study of which will render the diagnosis of nervous affections the more easy, and their treatment more successful. The book is very useful as a reference work to the busy practitioner, to whom we can recommend it.—*Medical and Surgical Reporter*, Jan. 21, 1882.

The most valuable, for the general purposes of the student and practitioner, of the host that has recently been published in the same field of professional literature.—*Amer. Practitioner*, May, 1882.

MITCHELL, S. WEIR, M. D.,

Physician to Orthopaedic Hospital and the Infirmary for Diseases of the Nervous System, Phila., etc.

Lectures on Diseases of the Nervous System; Especially in Women. Second edition. In one very handsome 12mo. volume of about 250 pages. *Preparing.*

The life-long devotion of the Author to the subjects discussed in this volume has rendered it eminently desirable that the results of his labors should be embodied for the benefit of those who may experience the difficulties connected with the treatment of this class of disease. Many of these lectures are fresh studies of hysterical affections; others treat of the modifications his views have undergone in regard to certain forms of treatment; while throughout the whole work he has been careful to keep in view the practical lessons of his cases.

A few notices of the previous edition are appended:—

It is a record of a number of very remarkable cases, with acute analyses and discussions, clinical, physiological and therapeutical. It is a book to which the physician meeting with a new hysterical experience, or in doubt whether his new ex-

perience is hysterical, may well turn with a well-grounded hope of finding a parallelism; it will be a new experience, indeed, if no similar one is here recorded.—*Phila. Medical Times*, June 4, 1881.

PLAYFAIR, W. S., M. D., F. R. C. P.

The Systematic Treatment of Nerve Prostration and Hysteria. In one handsome small 12mo. volume of 97 pages. Cloth, \$1.00. *Just ready.*

The book is well worth perusal, and will repay anyone for the time spent in its careful study, inasmuch as it will lead to a better understanding of the management of those *bêtes noires* of the physician, nerve prostration and hysteria. Details are given of the manner of carrying out the treatment,

to which are added the histories of a number of cases illustrative of the method and its results. An appendix contains a description of the method of performing massage, which is clear and concise.—*New Orleans Medical and Surgical Journal*, May, 1883.

TUKE, DANIEL HACK, M. D.,

Joint Author of The Manual of Psychological Medicine, etc.

Illustrations of the Influence of the Mind upon the Body in Health and Disease. Designed to illustrate the Action of the Imagination. New edition. In one handsome octavo volume. *Preparing.*

BLANDFORD, G. FIELDING, M. D., F. R. C. P.,

Lecturer on Psychological Medicine at the School of St. George's Hospital, London.

Insanity and its Treatment: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane, by ISAAC RAY, M. D. In one very handsome octavo volume.

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS, by C. HANDFIELD JONES,

M. D. Second American edition. In one handsome octavo volume of 340 pages. Cloth, \$3.25.

GROSS, S. D., M. D., LL. D., D. C. L. Oxon., LL. D. Cantab.,

Emeritus Professor of Surgery in the Jefferson Medical College of Philadelphia.

A System of Surgery: Pathological, Diagnostic, Therapeutic and Operative. Sixth edition, greatly enlarged and thoroughly revised by the Author and SAMUEL W. GROSS, A. M., M. D., Professor of the Principles of Surgery and of Clinical Surgery in the Jefferson Medical College. In two large and beautifully-printed imperial octavo volumes containing 2382 pages, illustrated by 1623 engravings. Strongly bound in leather, raised bands, \$15; half Russia, raised bands, \$16. *Just ready.*

The work as a whole needs no commendation. Many years ago it earned for itself the enviable reputation of the leading American work on surgery, and it is still capable of maintaining that standard. The reason for this need only be mentioned to be appreciated. The author has always been calm and judicious in his statements, has based his conclusions on much study and personal experience, has been able to grasp his subject in its entirety, and, above all, has conscientiously adhered to truth and fact, weighing the evidence, *pro* and *con*, accordingly. A considerable amount of new material has been introduced, and altogether the distinguished author has reason to be satisfied that he has placed the work fully abreast of the state of our knowledge.—*Med. Record*, Nov. 18, 1882.

We have purposely abstained from comment or criticism of the book before us. It has formerly been noticed more than once in our columns, and it is enough now to remark that the present edition fully maintains the reputation the work has acquired. Though Professor Gross' book is the outcome of his college lectures, the several parts have been extended, elaborated and amplified, till it has become a complete and systematic book of reference alike for the student and the practitioner.—*The London Lancet*, Jan. 27, 1883.

In the present issue he has, in addition to his own great work, called to his aid Prof. S. W. Gross, Drs. J. Solis-Cohen, George C. Harlan, Charles H. Burnett, William Thomson, Edward C. Seguin, Robert Battey, Lewis H. Sayre, Richard J. Duglison, and Surgeon-General Barnes, U. S. A. The author has conscientiously revised every page of the fifth edition, and in doing so has found it necessary to rewrite nearly every chapter, noting the extraordinary strides which surgery has made during the past fifty years.—*Cincinnati Lancet and Clinic*, Nov. 11, 1882.

We regard Gross' System of Surgery not only as a singularly rich storehouse of scientific information, but as marking an epoch in the literary history of surgery. The present edition has received the most careful revision at the hands of the eminent author himself, assisted in various instances by able specialists in various branches. All departments of the vast and ever-increasing literature of the science have been drawn upon for their most recent expressions. The late advances made in surgical practice have been carefully noted, such as the recent developments of Listerism and the improvements in gynecological operations. In every respect the work reflects lasting credit on American medical literature.—*Medical and Surgical Reporter*, Nov. 11, 1882.

ASHHURST, JOHN, Jr., M. D.,

Professor of Clinical Surgery, Univ. of Penna., Surgeon to the Episcopal Hospital, Philadelphia.

The Principles and Practice of Surgery. Third edition, enlarged and revised. In one large and handsome octavo volume of 1060 pages, with 555 illustrations. Cloth, \$6; leather, \$7; very handsome half Russia, raised bands, \$7.50. *Just ready.*

Dr. Ashhurst's *Surgery* is a condensed treatise covering the whole domain of the science in one manageable volume. The present edition has had a thorough revision. The novelties in surgical practice and the recent observations in surgical science have been incorporated, but the size of the volume has not been materially increased. The author's arrangement is perspicuous, and his language correct and clear. An excellent index closes the work, and on the whole we consider it the best system of surgery in one volume which could be named as the product of an American author.—*Medical and Surgical Reporter*, Oct. 28, '82.

The author, long known as a thorough student of surgery, and one of the most accomplished scholars in the country, aims to give in this work

"a condensed but comprehensive description of the modes of practice now generally employed in the treatment of surgical affections, with a plain exposition of the principles upon which these modes of practice are based." In this he has so well succeeded that it will be a surprise to the reader to know how much practical knowledge extending over such a wide range of research is compressed in a volume of this size. This feature of the work must be its best claim for continued popularity with students and practitioners. In fact, in this respect it is without an equal in any language. In the present edition many novelties in surgical practice are introduced, many modifications of previous statements made, and several new illustrations added.—*Med. Rec.*, Nov. 18, 1882.

GIBNEY, V. P., M. D.

Surgeon to the Orthopaedic Hospital, New York, etc.

Orthopaedic Surgery. For the use of Practitioners and Students. In one handsome octavo volume, profusely illustrated. *Preparing.*

ROBERTS, JOHN B., A. M., M. D.,

Lecturer on Anatomy and on Operative Surgery at the Philadelphia School of Anatomy.

The Principles and Practice of Surgery. For the use of Students and Practitioners of Medicine and Surgery. In one very handsome octavo volume of about 500 pages, with many illustrations. *Preparing.*

PEPPER, A. J., M. B., M. S., F. R. C. S.,

Surgeon and Lecturer at St. Mary's Hospital, London.

Surgical Pathology. (See *Students' Series of Manuals*, page 5.)

STIMSON, LEWIS A., B. A., M. D.,

Prof. of Pathol. Anat. at the Univ. of the City of New York, Surgeon and Curator to Bellevue Hosp.

A Manual of Operative Surgery. In one very handsome royal 12mo. volume of 477 pages, with 332 illustrations. Cloth, \$2.50.

BRYANT, THOMAS, F. R. C. S.,*Surgeon to Guy's Hospital, London.*

The Practice of Surgery. Third American from the third and revised English edition. Thoroughly revised and much improved, by JOHN B. ROBERTS, A. M., M. D. In one large and very handsome imperial octavo volume of 1009 pages, with 735 illustrations. Cloth, \$6.50; leather, \$7.50; very handsome half Russia, raised bands, \$8.00.

Without freighting his book with multiplied details and wearying descriptions of allied methods of procedure, he is ample enough for reference on all the departments of surgery, not omitting such strict specialties as dental, ophthalmic, military, orthopædic and gynæcological surgery. Some of these chapters are written by specialists in these respective branches, and all are amply sufficient for anyone not himself aiming at special practice. The labors of the American editor deserve unqualified praise. His additions to the author's text are numerous, judicious and germane. They add very distinctly to the value of the original treatise, and give a more equitable illustration of the part taken by American surgeons than the author was able to do.—*Medical and Surgical Reporter*, Feb. 12, 1881.

It is the best of all the one-volume works on surgery of recent date for the ordinary surgeon, containing enough of pathology, accurate description of surgical diseases and injuries, well-devised

plans of treatment, etc., to make the surgeon who follows the text successful in his diagnosis and treatment in any case in which success can be secured, according to the present state of the surgical art.—*Virginia Medical Monthly*, May, 1881.

It is a work especially adapted to the wants of students and practitioners. It affords instruction in sufficient detail for a full understanding of surgical principles and the treatment of surgical diseases. It embraces in its scope all the diseases that are recognized as belonging to surgery, and all traumatic injuries. In discussing these it has seemed to be the aim of the author rather to present the student with practical information, and that alone, than to burden his memory with the views of different writers, however distinguished they might have been. In this edition the whole work has been carefully revised, much of it has been rewritten, and important additions have been made to almost every chapter.—*Cincinnati Medical News*, Jan. 1881.

ERICHSEN, JOHN E., F. R. S., F. R. C. S.,*Professor of Surgery in University College, London, etc.*

The Science and Art of Surgery; Being a Treatise on Surgical Injuries, Diseases and Operations. Specially revised by the Author from the eighth and enlarged English edition. In two large and beautiful octavo volumes of about 2000 pages, illustrated with about 900 engravings on wood. *Preparing.*

A few notices of the previous edition are appended.

Of the many treatises on surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Medical and Surgical Reporter*, Feb. 2, 1878.

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better that the work almost appears as an entirely new one.—*Medical Record*, Feb. 23, 1878.

ESMARCH, Dr. FRIEDRICH,*Professor of Surgery at the University of Kiel, etc.*

Early Aid in Injuries and Accidents. Five Ambulance Lectures. Translated by H. R. H. PRINCESS CHRISTIAN. In one handsome small 12mo. volume of 109 pages, with 24 illustrations. Cloth, 75 cents. *Just ready.*

The excellent little handbook by Dr. Esmarch may be referred to by all for clear, safe and practical directions and instructions for rendering the right kind of aid until the doctor arrives, in the event of the numerous injuries that are liable to happen in a family or neighborhood in the circumstances of daily life. The manual is earnestly and justly commended for its excellence and clearness, and especially for the minuteness and extent of its practical details.—*Harpers' Magazine*, Aug., 1883.

The course of instruction is divided into five sections or lectures. The first, or introductory lecture, gives a brief account of the structure and

organization of the human body, illustrated by clear, suitable diagrams. The second teaches how to give judicious help in ordinary injuries—contusions, wounds, hæmorrhage and poisoned wounds. The third treats of first aid in cases of fracture and of dislocations, in sprains and in burns. Next, the methods of affording first treatment in cases of frost-bite, of drowning, of suffocation, of loss of consciousness and of poisoning are described; and the fifth lecture teaches how injured persons may be most safely and easily transported to their homes, to a medical man, or to a hospital. The illustrations in the book are clear and good.—*Medical Times and Gazette*, Nov. 4, 1882.

DRUITT, ROBERT, M. R. C. S., etc.

The Principles and Practice of Modern Surgery. From the eighth London edition. In one octavo volume of 687 pages, with 432 illustrations. Cloth, \$4.00; leather, \$5.00.

SARGENTON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with a Chapter on military surgery. One 12mo. volume of 383 pages, with 187 cuts. Cloth, \$1.75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American from the third Edinburgh edition. In one 8vo. vol. of 688 pages, with 340 illustrations. Cloth, \$3.75.

MILLER'S PRACTICE OF SURGERY. Fourth and revised American from the last Edinburgh edition. In one large 8vo. vol. of 682 pages, with 364 illustrations. Cloth, \$3.75.

PIRRIE'S PRINCIPLES AND PRACTICE OF SURGERY. Edited by JOHN NEILL, M. D. In one 8vo. vol. of 784 pp. with 316 illus. Cloth, \$3.75.

COOPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In one 8vo. vol. of 767 pages. Cloth, \$2.00.

SKEY'S OPERATIVE SURGERY. In one vol. 8vo. of 661 pages, with 81 woodcuts. Cloth, \$3.25.

GIBSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edition. In two octavo vols. of 966 pages, with 34 plates. Leather \$6.50.

HOLMES, TIMOTHY, M. A.,*Surgeon and Lecturer on Surgery at St. George's Hospital, London.*

A System of Surgery; Theoretical and Practical. IN TREATISE VARIOUS AUTHORS. AMERICAN EDITION, THOROUGHLY REVISED AND RE-EDITED by JOHN H. PACKARD, M. D., Surgeon to the Episcopal and St. Joseph's Hospitals, Philadelphia, assisted by a corps of thirty-three of the most eminent American surgeons. In three large and very handsome imperial octavo volumes containing 3137 double-columned pages, with 979 illustrations on wood and 13 lithographic plates, beautifully colored. Price per volume, cloth, \$6.00; leather, \$7.00; half Russia, \$7.50. Per set, \$18.00; leather, \$21.00; half Russia, \$22.50. *Sold only by subscription.*

VOLUME I. contains GENERAL PATHOLOGY, MORBID PROCESSES, INJURIES IN GENERAL, COMPLICATIONS OF INJURIES AND INJURIES OF REGIONS.

VOLUME II. contains DISEASES OF ORGANS OF SPECIAL SENSE, CIRCULATORY SYSTEM, DIGESTIVE TRACT AND GENITO-URINARY ORGANS.

VOLUME III. contains DISEASES OF THE RESPIRATORY ORGANS, BONES, JOINTS, MUSCLES, DISEASES OF THE NERVOUS SYSTEM, GUNSHOT WOUNDS, OPERATIVE MINOR SURGERY, AND MISCELLANEOUS SUBJECTS (including an essay on HOSPITALS).

This great work, issued some years since in England, has won such universal fame and approval wherever the language is spoken that its republication here, in a form thoroughly adapted to the wants of the American practitioner, has seemed to be a matter of course. To accomplish this, each article has been placed in the hands of a gentleman specially competent to treat its subject, and no labor has been spared to bring each one up to the foremost level of the times, and to adapt it thoroughly to the practice of the country. In certain cases this has rendered necessary the substitution of an entirely new essay for the original, as in the case of the articles on Skin Diseases and on Diseases of the Absorbent System, where the views of the authors have been superseded by the advance of medical science, and new articles have therefore been prepared by Drs. A. Van Harlingen and S. C. Busey, respectively. So also in the case of Anæsthetics, in the use of which American practice differs from that of England, the original has been supplemented with a new essay by J. C. Reeve, M. D. The same careful and conscientious revision has been pursued throughout, leading to an increase of nearly one-fourth the number of pages, while the series of illustrations has been nearly trebled, and the whole is presented as a complete exponent of British and American Surgery, adapted to the daily needs of the working practitioner.

In order to bring it within the reach of every member of the profession, the five volumes of the original have been compressed into three by employing a double-columned royal octavo page, and in this improved form it is offered at less than one-half the price of the original. It is printed and bound to match in every detail with Reynolds' System of Medicine. The work will be sold by subscription only, and in due time every member of the profession will be called upon and offered an opportunity to subscribe.

The authors of the original English edition are men of the front rank in England, and Dr. Packard has been fortunate in securing as his American coadjutors such men as Bartholow, Hyde, Hunt, Conner, Stimson, Morton, Hodgkin, Jewell and their colleagues. As a whole, the work will be solid and substantial, and a valuable addition to the library of any medical man. It is more wieldy and more useful than the English edition, and with its companion work—"Reynolds' System of Medicine"—will well represent the present state of our science. One who is familiar with those two works will be fairly well furnished head-wise and hand-wise.—*The Medical News*, Jan. 7, 1882.

This work is cyclopædic in character, and every subject is treated in an exhaustive manner. It is especially designed for a reference book, which every practising surgeon should have under hand in cases which require more than ordinary knowledge.—*Chicago Med. Journ. and Exam.*, Feb. 1882.

Great credit is due to the American editor and his co-laborers for revising and bringing within

easy reach of American surgeons a work which has been received with such universal favor on the other side of the Atlantic as Holmes' System of Surgery. In the list of English contributors to the first volume we find the names of such well-known surgeons as Sir James Paget, Simon, Savor, Lender, Barclay, and others equally distinguished, while among the American revisers we find the names of men of no less celebrity. With regard to the mechanical execution of the work, neither time nor money seem to have been spared by the publishers.—*Med. and Surg. Reporter*, Sept. 14, 1881.

In the revision of the work for the American edition not only has provision been made for the recognition of the advances made in our knowledge during the ten years since its first publication, but also for a presentation of the variations in practice which characterize American surgery, and which distinguish it from that of Great Britain. The work is one which we take pleasure in recommending to the notice of our readers as an epitome of surgical knowledge and practice.—*St. Louis Courier of Medicine*, Nov. 1881.

HOLMES, TIMOTHY, M. A.

Surgery, Its Principles and Practice. In one handsome octavo volume of 968 pages, with 411 illustrations. Cloth, \$6.00; leather, \$7.00; half Russia, \$7.50.

Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has no time to give attention to more minute and extended works, and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincin. Med. News*, 1876.

STIMSON, LEWIS A., B. A., M. D.,

Professor of Pathological Anatomy at the University of the City of New York, Surgeon and Curator to Bellevue Hospital, Surgeon to the Presbyterian Hospital, New York, etc.

A Practical Treatise on Fractures. In one very handsome octavo volume of 598 pages, with 360 beautiful illustrations. Cloth, \$4.75; leather, \$5.75. *Just Ready.*

The author has given to the medical profession in this treatise on fractures what is likely to become a standard work on the subject. It is certainly not surpassed by any work written in the English, or, for that matter, any other language. Perfectly conversant with the American, English, French and German medical literature, the author tells us in a short, concise and comprehensive manner, all that is known about his subject. There is nothing scanty or superficial about it, as in most other

treatises; on the contrary, everything is thorough. The chapters on repair of fractures and their treatment show him not only to be a profound student, but likewise a practical surgeon and pathologist. His mode of treatment of the different fractures is eminently sound and practical. We consider this work one of the best on fractures; and it will be welcomed not only as a text-book, but also by the surgeon in full practice.—*N. O. Medical and Surgical Journal*, March, 1883.

HAMILTON, FRANK H., M. D., LL. D.,

Surgeon to the Bellevue Hospital, New York.

A Practical Treatise on Fractures and Dislocations. Sixth edition, thoroughly revised and much improved. In one very handsome octavo volume of 909 pages, with 352 illustrations. Cloth, \$5.50; leather, \$6.50; half Russia, raised bands, \$7.00.

The only complete work on its subject in the English tongue, and indeed it may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which it might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Medical News*, Nov. 10, 1881.

Dr. Hamilton is the author of the best modern work in his own or any language on fractures and dislocations.—*Lond. Med. Times and Gaz.* Nov. 19, '81.

This edition, besides being carefully revised, has in part been entirely rewritten—for instance, the chapter on fractures of the patella—and a chapter on general prognosis has been added. The work as a whole is one of the very few medical books of American origin that are everywhere accorded a standard character. Its subject-matter unavoidably comes home to every general practitioner as a branch of our art in which he cannot afford to neglect the fullest and most practical information of such a character as it and it alone furnishes.—*New York Medical Journal*, March, 1881.

WELLS, J. SOELBERG, F. R. C. S.,

Professor of Ophthalmology in King's College Hospital, London, etc.

A Treatise on Diseases of the Eye. Fourth American from the third London edition. Thoroughly revised, with copious additions, by CHARLES S. BULL, M. D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. In one large and very handsome octavo volume of 822 pages, with 257 illustrations on wood, six colored plates, and selections from the Test-types of Jaeger and Snellen. Cloth, \$5.00; leather, \$6.00; very handsome half Russia, raised bands, \$6.50. *Just ready.*

This new edition of this well-known and standard work has been revised by Dr. Charles S. Bull, who has endeavored to carry out the original plan of the Author by incorporating all advances in the subject up to the present day, and, in addition, to give due prominence to the views in theory and practice which ophthalmic science owes to this country. As now offered to the profession, this volume may therefore be said to represent its specialty in its most advanced condition on both sides of the Atlantic.

NETTLESHIP, EDWARD, F. R. C. S.,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

The Student's Guide to Diseases of the Eye. New edition. With a chapter on the Detection of Color-Blindness, by WILLIAM THOMSON, M. D., Ophthalmologist to the Jefferson Medical College. In one royal 12mo. volume of 416 pages, with 138 illustrations. Cloth, \$2.00. *Just ready.*

This admirable guide bids fair to become the favorite text-book on ophthalmic surgery with students and general practitioners. It bears throughout the imprint of sound judgment combined with vast experience. The illustrations are numerous and well chosen. This book, within the short compass of about 400 pages, contains a lucid exposition of the modern aspect of ophthalmic science.—*Medical Record*, June 23, 1883.

This work is essentially a student's manual of ophthalmology, and the favor with which it has

been received shows its real value and the appreciation by the profession of its intrinsic merits. Dr. Thomson has added a Chapter on Color-Blindness, on which subject his extensive investigations are well known. With this valuable addition the book becomes the most valuable guide to diseases of the eye yet published. We commend it to the notice of students of medicine, and to such practitioners as desire a condensed treatise on a class of diseases which are frequently met with in daily practice.—*Buffalo Med. and Surg. Journ.*, May, 1883.

BROWNE, EDGAR A.,

Surgeon to the Liverpool Eye and Ear Infirmary and to the Dispensary for Skin Diseases.

How to Use the Ophthalmoscope. Being Elementary Instructions in Ophthalmoscopy, arranged for the use of Students. In one small royal 12mo. volume of 116 pages, with 35 illustrations. Cloth, \$1.00.

LAWSON ON INJURIES TO THE EYE, ORBIT AND EYELIDS: Their Immediate and Remote Effects. In one octavo volume of 404 pages, with 92 illustrations. Cloth, \$3.50.

LAURENCE AND MOON'S HANDY BOOK OF OPHTHALMIC SURGERY, for the use of Prac-

tioners. Second edition. In one octavo volume of 227 pages, with 65 illust. Cloth, \$2.75.

CARTER'S PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited by JOHN GREEN, M. D. In one handsome octavo volume.

BURNETT, CHARLES H., A. M., M. D.,*Aural Surg. to the Presb. Hosp., Surgeon-in-charge of the Instr. for Dis. of the Ear, Philadelphia.*

The Ear, Its Anatomy, Physiology and Diseases. A Practical Treatise for the use of Medical Students and Practitioners. In one handsome octavo volume of 611 pages, with 87 illustrations. Cloth, \$4.50; leather, \$5.50; half Russia, raised bands, \$6.00.

The medical profession will welcome this new work on otology, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett has produced a work which, as a text-book, stands *facile princeps* in our language. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the care-

ful study of the book and a constant reference to its trustworthy pages.—*Edinburgh Med. Jour.* Aug. 7.

As the title of the work indicates, this volume treats of the anatomy and physiology of the ear as well as of its diseases, and the author has taken special pains to make this difficult and complicated matter thoroughly clear and intelligible. Both student and practitioner can study the work with a great deal of benefit. It is profusely and beautifully illustrated.—*N. Y. Hosp. Gazette*, Oct. 15, 1877.

POLITZER, ADAM, M. D.,*Imperial-Royal Prof. of Aural Therap. in the Univ. of Vienna.*

A Text-Book of the Ear and its Diseases. Translated, at the Author's request, by JAMES PATTERSON CASSELLS, M. D., M. R. C. S. In one handsome octavo volume of 800 pages, with 257 original illustrations. Cloth, \$5.50. *Just ready.*

The work itself we do not hesitate to pronounce the best upon the subject of aural diseases which has ever appeared, systematic without being too diffuse on obsolete subjects, and eminently practical in every sense. The anatomical descriptions of each separate division of the ear are admirable, and profusely illustrated by woodcuts. They are followed immediately by the physiology of the

section, and this again by the pathological physiology, an arrangement which serves to keep up the interest of the student by showing the direct application of what has preceded to the study of disease. The whole work can be recommended as a reliable guide to the student, and an efficient aid to the practitioner in his treatment.—*Boston Medical and Surgical Journal*, June 7, 1883.

COLEMAN, A., L. R. C. P., F. R. C. S., Exam. L. D. S.,*Senior Dent. Surg. and Lect. on Dent. Surg. to St. Bartholomew's Hosp. and the Dent. Hosp., London.*

A Manual of Dental Surgery and Pathology. Thoroughly revised and adapted to the use of American Students, by THOMAS C. STELLWAGEN, M. A., M. D., D. D. S., Prof. of Physiology at the Philadelphia Dental College. In one handsome volume of 412 pages, with 331 illustrations. Cloth, \$3.25.

This volume deserves to rank among the most important of recent contributions to dental literature. Mr. Coleman has presented his methods of practice, for the most part, in a plain and concise manner, and the work of the American editor has been conscientiously performed. He has evidently labored to present his convictions of the best modes of practice for the instruction of those commencing a professional career, and he has faithfully endeavored to teach to others all that he has acquired by his own observation and experience. The book

deserves a place in the library of every dentist.—*Dental Cosmos*, May, 1882.

It should be in the possession of every practitioner in this country. The part devoted to first and second dentition and irregularities in the permanent teeth is fully worth the price. In fact, the price should not be considered in purchasing such a work. If the money put into some of our so-called standard text-books could be converted into such publications as this, much good would result.—*Southern Dental Journal*, May, 1882.

GROSS, S. D., M. D., LL. D., D. C. L., etc.

A Practical Treatise on the Diseases, Injuries and Malformation of the Urinary Bladder, the Prostate Gland and the Urethra. Third edition, thoroughly revised by SAMUEL W. GROSS, M. D., Surgeon to the Philadelphia Hospital. In one octavo volume of 574 pages, with 170 illustrations. Cloth, \$4.50.

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise. Replete with handsome illustrations and good ideas, it has the un-

sual advantage of being easily comprehended in the reasonable and practical manner in which the various subjects are systematized and arranged.—*Atlanta Medical Journal*, Oct. 1876.

ROBERTS, WILLIAM, M. D.,*Lecturer on Medicine in the Manchester School of Medicine, etc.*

A Practical Treatise on Urinary and Renal Diseases, including Urinary Deposits. Fourth American from the fourth London edition. Illustrated by numerous engravings. In one large and handsome octavo volume. *Preparing.*

THOMPSON, SIR HENRY,*Surgeon and Professor of Clinical Surgery to University College Hospital, London.*

Lectures on Diseases of the Urinary Organs. Second American from the third English edition. In one 8vo. volume of 203 pp., with 25 illustrations. Cloth, \$2.25.

By the Same Author.

On the Pathology and Treatment of Stricture of the Urethra and Urinary Fistulæ. From the third English edition. In one volume of 359 pages, with 47 cuts and 3 plates. Cloth, \$3.50.

BASHAM ON RENAL DISEASES: A Clinical Guide to their Diagnosis and Treatment. In

one 12mo. vol. of 304 pages, with 21 illustrations. Cloth, \$2.00.

GROSS, SAMUEL W., A. M., M. D.,*Professor of the Principles of Surgery and of Clinical Surgery in the Jefferson Medical College.***A Practical Treatise on Impotence, Sterility, and Allied Disorders of the Male Sexual Organs.** Second edition, thoroughly revised. In one very handsome octavo volume of 168 pages, with 16 illustrations. Cloth, \$1.50. *Just ready.*

A few notices of the previous edition are appended.

The book is the outcome of intelligent clinical observation and extensive experience. The arrangement and classification leave nothing to be desired in the way of clearness; and practitioners who may be called upon to treat these cases will find the directions both for diagnosis and treatment very perspicuous and sound.—*Liverpool Medico-Chirurgical Journal*, July, 1882.

The author has devoted much time to the hardest study of this most trying class of diseases; and this labor, together with the fruit of laborious research into the scattered literature of the subject, constitutes the result of his investigations. We can earnestly commend it to the practitioner as the very best work upon the subject in the English language.—*Nashville Jour. of Med. and Surg.* Oct. '81.

BUMSTEAD, F. J., and**M. D., LL. D.,***Late Professor of Venereal Diseases at the College of Physicians and Surgeons, New York, etc.***TAYLOR, R. W.,****A. M., M. D.,***Surgeon to Charity Hospital, New York, Prof. of Venereal and Skin Diseases in the University of Vermont, Pres. of the Am. Dermatological Ass'n.***The Pathology and Treatment of Venereal Diseases.** Including the results of recent investigations upon the subject. Fifth edition, revised and largely rewritten, by Dr. Taylor. In one large and handsome octavo volume of about 900 pages, with about 150 illustrations. *In press.*

The fifth edition of this standard work, now passing through the press, has been subjected to a thorough revision by Dr. Taylor, and all additions have been made necessary to render it thoroughly representative of the present state of syphilology. Recent advanced theories have been fully discussed; space has been devoted to a detailed account of a newly-discovered agent which has been proved of striking value in the treatment of venereal diseases, and a chapter has been added upon the relation of syphilis to marriage. In addition to the improvements in the text, a series of carefully-executed chromolithographic drawings has been inserted, portraying faithfully those morbid conditions impossible to depict without the use of colors. Every care has been taken with the typography, and it is confidently anticipated that the volume will be found in all respects worthy of the exalted position accorded the previous editions.

CORNIL, V.,*Professor to the Faculty of Medicine of Paris, and Physician to the Lourcine Hospital.***Syphilis, its Morbid Anatomy, Diagnosis and Treatment.** Specially revised by the Author, and translated with notes and additions by J. HENRY C. SIMES, M. D., Demonstrator of Pathological Histology in the University of Pennsylvania, and J. WILLIAM WHITE, M. D., Lecturer on Venereal Diseases and Demonstrator of Surgery in the University of Pennsylvania. In one handsome octavo volume of 461 pages, with 84 very beautiful illustrations. Cloth, \$3.75. *Just ready.*

The anatomical and histological characters of the hard and soft sore are admirably described. The multiform cutaneous manifestations of the disease are dealt with histologically in a masterly way, as we should indeed expect them to be, and the accompanying illustrations are executed carefully and well. The various nervous lesions which are the recognized outcome of the syphilitic dyscrasia are treated with care and consideration. Syphilitic epilepsy, paralysis, cerebral syphilis and locomotor ataxia are subjects full of interest; and nowhere in the whole volume is the clinical experience of the author or the wide acquaintance of the translators with medical literature more evident. The anatomy, the histology, the pathology and the clinical features of syphilis are represented in this work in their best, most practical and most instructive form, and no one will rise from its perusal without the feeling that his grasp of the wide and important subject on which it treats is a stronger and surer one.—*The London Practitioner*, Jan. 1882.

It is with the special purpose of showing the evolution of the disease as indicated by histological

changes that the author has prepared this volume. In this respect, it is much better than any other we could name, and merits the close reading of syphilologists. The translation is well done, and the reader will not regret the considerable additions which the translators have inserted in the text.—*Medical and Surgical Reporter*, Aug. 5, 1882.

The characteristic feature of M. Cornil's work is the attention paid to the minute anatomy of the syphilitic lesions. The histological evolution of the various phases of the disease, from the initial chancre to the gumma, including the mucous patch, the superficial and deep cutaneous syphilides, the osseous and visceral affections—is considered with a detail that is in striking contrast to that of other works upon the same subject. The translation has been made with his consent and approval, and he is fortunate in the selection of his translators, for they have added materially to the interest and value of the volume.—*Maryland Medical Journal*, Aug. 15, 1882.

CULLERIER, A., & BUMSTEAD, F. J., M. D., LL. D.,*Surgeon to the Hôpital du Midi.**Late Professor of Venereal Diseases in the College of Physicians and Surgeons, New York.***An Atlas of Venereal Diseases.** Translated and edited by FREEMAN J. BUMSTEAD, M. D. In one imperial 4to. volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life. Strongly bound in cloth, \$17.00. A specimen of the plates and text sent by mail, on receipt of 25 cts.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. In one 8vo vol. of 479 p. Cloth, \$3.25. **FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION.** In one 8vo. vol. of 246 pages. Cloth, \$2.25.

HYDE, J. NEVINS, M. D.,*Professor of Dermatology and Venereal Diseases in Rush Medical College, Chicago.*

A Practical Treatise on Diseases of the Skin. For the use of Students and Practitioners. In one handsome octavo volume of 570 pages, with 66 beautiful and elaborate illustrations. Cloth, \$4.25; leather, \$5.25. *Just ready.*

EXTRACT FROM PREFACE.

The increasing recognition of the gravity of many cutaneous disorders and of the importance of their accurate study, is shown by the rapidly augmenting number of observers in this department of medicine and by the numerous and valuable contributions constantly made to it both in this country and abroad. For the convenience of the general practitioner it therefore becomes necessary at shortly-recurring intervals that some one should attempt the task of presenting in a comprehensive form the results of the latest observation and experience. The author is aware of the extent to which he must claim indulgence in the present effort to perform this duty. The extent of the subject and the limitations of a single volume require the omission of much detail of secondary importance. With regard to that which it has seemed proper to include he has endeavored to write concisely, to set forth only what can be held as the truth, to be frank in the admission of the weakness with which the most skilful physician stands in the presence of many grave and not a few benign disorders, and to cultivate a wholesome doubt of that which has not been shown to be worthy of trust.

Professor Hyde has long been known as one of the most intelligent and enthusiastic representatives of dermatology in the west. His numerous contributions to the literature of this specialty have gained for him a favorable recognition as a careful, conscientious and original observer. The remarkable advances made in our knowledge of diseases of the skin, especially from the standpoint of pathological histology and improved methods of treatment, necessitate a revision of the older text-books at short intervals in order to bring them up to the standard demanded by the march of science. This last contribution of Dr. Hyde is an effort in this direction. He has attempted, as he informs us, the task of presenting in a condensed form the results of the latest observation and experience. A careful examination

of the work convinces us that he has accomplished his task with painstaking fidelity and with a creditable result.—*Journal of Cutaneous and Venereal Diseases*, June, 1883.

Prof. Hyde has given to the profession a valuable and comprehensive work upon this special subject, exposing the etiology, symptomatology and treatment of diseases of the skin in a concise and thorough manner. The book is a valuable one for the student and practitioner, containing all the latest progress made in dermatology, and will without doubt attain the end expected by its author—to make the general practitioner thoroughly informed in regard to the treatment of cutaneous diseases, and it will prove a valuable book of reference to the specialist.—*New Orleans Medical and Surgical Journal*, April, 1883.

MORRIS, MALCOLM, M. D.,*Joint Lecturer on Dermatology at St. Mary's Hospital Medical School, London.*

Skin Diseases; Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy and Treatment. A Manual for Students and Practitioners. In one 12mo. volume of 316 pages, with illustrations. Cloth, \$1.75.

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advises.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature there is no book of a like scope which for clearness of ex-

pression and methodical arrangement is better adapted to promote a rational conception of dermatology—a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The writer has certainly given in a small compass a large amount of well-compiled information, and his little book compares favorably with any other which has emanated from England, while in many points he has emancipated himself from the stubbornly adhered to errors of others of his countrymen. There is certainly excellent material in the book which will well repay perusal.—*Boston Med. and Surg. Journ.*, March, 1880.

FOX, T., M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,*Physician to the Department for Skin Diseases, University College Hospital, London.*

WILSON, ERASMUS, F. R. S.

The Student's Book of Cutaneous Medicine and Diseases of the Skin. In one handsome small octavo volume of 535 pages. Cloth, \$3.50.

HILLIER, THOMAS, M. D.,*Physician to the Skin Department of University College, London.*

Handbook of Skin Diseases; for Students and Practitioners. Second American edition. In one 12mo. volume of 353 pages, with plates. Cloth, \$2.25.

AN AMERICAN SYSTEM OF GYNÆCOLOGY.

A System of Gynæcology, in Treatises by Various Authors. In active preparation.

THOMAS, T. GAILLARD, M. D.,

Professor of Obstetrics, etc., in the College of Physicians and Surgeons, N. Y.

A Practical Treatise on the Diseases of Women. Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of 810 pages, with 266 illustrations. Cloth, \$5.00; leather, \$6.00; very handsome half Russia, raised bands, \$6.50.

The words which follow "fifth edition" are in this case no mere formal announcement. The alterations and additions which have been made are both numerous and important. The attraction and the permanent character of this book lie in the clearness and truth of the clinical descriptions of diseases; the fertility of the author in therapeutic resources and the fulness with which the details of treatment are described; the definite character of the teaching; and last, but not least, the evident candor which pervades it. We would also particularize the fulness with which the history of the subject is gone into, which makes the book additionally interesting and gives it value as a work of reference.—*London Medical Times and Gazette*, July 30, 1881.

The determination of the author to keep his book foremost in the rank of works on gynæcology is most gratifying. Recognizing the fact that this can only be accomplished by frequent and thorough revision, he has spared no pains to make the present edition more desirable even than the previous one. As a book of reference for the busy practitioner it is unequalled.—*Boston Medical and Surgical Journal*, April 7, 1880.

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner.—*Nashville Jour. of Med. and Surg.*, Jan. 1881.

That the previous editions of the treatise of Dr. Thomas were thought worthy of translation into German, French, Italian and Spanish, is enough to give it the stamp of genuine merit. At home it has made its way into the library of every obstetrician and gynæcologist as a safe guide to practice. No small number of additions have been made to the present edition to make it correspond to recent improvements in treatment.—*Pacific Medical and Surgical Journal*, Jan. 1881.

EDIS, ARTHUR W., M. D., Lond., F. R. C. P., M. R. C. S.,

Assist. Obstetric Physician to Middlesex Hospital, late Physician to British Lying-in Hospital.

The Diseases of Women. Including their Pathology, Causation, Symptoms, Diagnosis and Treatment. A Manual for Students and Practitioners. In one handsome octavo volume of 576 pages, with 148 illustrations. Cloth, \$3.00; leather, \$4.00.

It is a pleasure to read a book so thoroughly good as this one. The special qualities which are conspicuous are thoroughness in covering the whole ground, clearness of description and conciseness of statement. Another marked feature of the book is the attention paid to the details of many minor surgical operations and procedures, as, for instance, the use of tents, application of leeches, and use of hot water injections. These are among the more common methods of treatment, and yet very little is said about them in many of the text-books. The book is one to be warmly recommended especially to students and general practitioners, who need a concise but complete résumé of the whole subject. Specialists, too, will find many useful hints in its pages.—*Boston Med. and Surg. Journ.*, March 2, 1882.

The greatest pains have been taken with the sections relating to treatment. A liberal selection of remedies is given for each morbid condition, the strength, mode of application and other details

being fully explained. The descriptions of gynæcological manipulations and operations are full, clear and practical. Much care has also been bestowed on the parts of the book which deal with diagnosis—we note especially the pages dealing with the differentiation, one from another, of the different kinds of abdominal tumors. The practitioner will therefore find in this book the kind of knowledge he most needs in his daily work, and he will be pleased with the clearness and fulness of the information there given.—*The Practitioner*, Feb. 1882.

It is an excellent manual—clear, decided, sufficiently comprehensive for a beginner, extremely handy for any practitioner, safe, cautious and precise. The book reminds us constantly of Thomas' treatise, on which it seems to have been somewhat modelled. As a summary of existing knowledge, empirical and other, it is really to be commended.—*Archives of Medicine*, June, 1882.

BARNES, ROBERT, M. D., F. R. C. P.,

Obstetric Physician to St. Thomas' Hospital, London, etc.

A Clinical Exposition of the Medical and Surgical Diseases of Women. In one handsome octavo volume, with numerous illustrations. New edition. Preparing.

GUSSEROW, A.,

Professor of Midwifery and the Diseases of Children at the University of Berlin.

A Practical Treatise on Uterine Tumors. Specially revised by the Author, and translated with notes and additions by EDMUND C. WENDT, M. D., Pathologist to the St. Francis Hospital, N. Y., etc., and revised by NATHAN BOZEMAN, M. D., Surgeon to the Woman's Hospital of the State of New York. In one handsome octavo volume, with about 40 illustrations. Preparing.

CHADWICK, JAMES R., A. M., M. D.

A Manual of the Diseases Peculiar to Women. In one handsome royal 12mo. volume, with illustrations. Preparing.

WEST, CHARLES, M. D.

Lectures on the Diseases of Women. Third American from the third London edition. In one octavo volume of 543 pages. Cloth, \$3.75; leather, \$4.75.

EMMET, THOMAS ADDIS, M. D., LL. D.,*Surgeon to the Woman's Hospital, New York, etc.*

The Principles and Practice of Gynecology; For the use of Students and Practitioners of Medicine. Second edition. Thoroughly revised. In one large and very handsome octavo volume of 879 pages, with 133 illustrations. Cloth, \$5.00; leather, \$6.00; very handsome half Russia, \$6.50.

No gynecological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynecology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Medical Gazette*, April 5, 1880.

In no country of the world has gynecology re-

ceived more attention than in America. It is then, with a feeling of pleasure that we welcome work on diseases of women from so eminent a gynecologist as Dr. Emmet. The work is essentially clinical, and leaves a strong impress of the author's individuality. To criticise, with the care it merits, the book throughout, would demand more space than is at our command. In particular we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*British Med. Journal*, Feb. 21, 1880.

DUNCAN, J. MATTHEWS, M.D., LL. D., F. R. S. E., etc.

Clinical Lectures on the Diseases of Women; Delivered in Saint Bartholomew's Hospital. In one handsome octavo volume of 175 pages. Cloth, \$1.50.

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a

stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infect the gynecology of the present day.—*N. F. Medical Journal*, March, 1880.

GYNECOLOGICAL TRANSACTIONS.*Being the Transactions of the American Gynecological Society for the Year 1881.*

VOLUME VI. Now ready. Contains Essays by Doctors W. H. Byford, S. C. Busey, H. J. Garrigues, G. H. Lyman, Nathan Bozeman, E. Van de Warker, I. E. Taylor, W. Goodell, H. F. Campbell, T. G. Thomas, T. A. Reamy, A. H. Smith, A. D. Sinclair, J. W. Underhill, E. W. Jenks, LL. D., W. M. Polk, W. R. Gillette, C. C. Lee, F. P. Foster, M. W. Sawyer and B. B. Browne.

With Indexes: (a) of Vol. VI., (b) of the Gynecological and Obstetric Literature of Countries for the year 1880, (c) of Obstetric and Gynecological Journals, and (d) of Obstetric and Gynecological Societies.

In one very handsome octavo volume of 549 pages, with illustrations. Cloth, \$5.00. Volumes I., III., IV. and V. may also be obtained. Price, each, by mail, postpaid, \$5.00.

HODGE, HUGH L., M. D.,*Emeritus Professor of Obstetrics, etc., in the University of Pennsylvania.*

On Diseases Peculiar to Women; Including Displacements of the Uterus. Second edition, revised and enlarged. In one beautifully printed octavo volume of 512 pages, with original illustrations. Cloth, \$4.50.

PLAYFAIR, W. S., M. D., F. R. C. P.,*Professor of Obstetric Medicine in King's College, London, etc.*

A Treatise on the Science and Practice of Midwifery. Third American edition, revised by the Author. Edited, with additions, by ROBERT P. HARRIS, M. D. In one handsome octavo volume of 659 pages, with 183 illustrations. Cloth, \$4; leather, \$5; half Russia, \$5.50.

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy. The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Medical and Surgical Journal*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, *par excellence*, we would undoubtedly advise him to

choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligible idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Medical News*, Jan. 1880.

It certainly is an admirable exposition of the science and practice of midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880.

KING, A. F. A., M. D.,*Professor of Obstetrics and Diseases of Women in the Medical Department of the Columbian University, Washington, D. C., and in the University of Vermont, etc.*

A Manual of Obstetrics. In one very handsome 12mo. volume of 321 pages, with 58 illustrations. Cloth, \$2.

Though the book appears small externally, it contains as complete a consideration of obstetric subjects as many larger volumes, and this is chiefly owing to a directness of expression, and an avoidance of repetition and of waste of words. The author endeavors to place theories, causes of disease and methods of treatment in that order which, by weight of authority, they merit. His excellent judgment has availed him well in this effort. While, in one sense, the book is an excel-

lent obstetric dictionary, and well suited to the student, it is also of value to the general practitioner, who often desires to find a *résumé* of information upon a given subject. It will be of further value to the latter, as, in our opinion, the author holds most sensible views on practical matters. The book is admirably arranged for reference, being well paragraphed, with suitable sub-divisions, and well indexed.—*American Journal of Obstetrics*, Aug. 1882.

TARNIER, S., and CHANTREUIL, G.

A Treatise on the Art of Obstetrics. Translated from the French. In two large octavo volumes, richly illustrated.

PARVIN, THEOPHILUS, M. D., LL. D.,*Professor of Obstetrics and the Diseases of Women and Children in the Jefferson Medical College.*

A Treatise on Midwifery. In one very handsome octavo volume of about 550 pages, with numerous illustrations. *In press.*

BARNES, ROBERT, M. D., and FANCOURT, M. D.,*Phys. to the General Lying-in Hosp., Lond.**Obstetric Phys. to St. Thomas' Hosp., Lond.*

A System of Obstetric Medicine and Surgery, Theoretical and Clinical. For the Student and the Practitioner. The Section on Embryology contributed by Prof. Milnes Marshall. In one handsome octavo volume, profusely illustrated. *In press.*

BARNES, FANCOURT, M. D.

A Manual of Midwifery for Midwives and Medical Students. In one royal 12mo. volume of 197 pages, with 50 illustrations. Cloth, \$1.25.

PARRY, JOHN S., M. D.,*Obstetrician to the Philadelphia Hospital, Vice-President of the Obstet. Society of Philadelphia.*

Extra - Uterine Pregnancy: Its Clinical History, Diagnosis, Prognosis and Treatment. In one handsome octavo volume of 272 pages. Cloth, \$2.50.

TANNER, THOMAS HAWKES, M. D.

On the Signs and Diseases of Pregnancy. First American from the second English edition. In one handsome octavo volume of 490 pages, with 4 colored plates and 16 woodcuts. Cloth, \$4.25.

WINCKEL, F.

A Complete Treatise on the Pathology and Treatment of Childbed. For Students and Practitioners. Translated, with the consent of the Author, from the second German edition, by JAMES READ CHADWICK, M. D. In one octavo volume of 484 pages. Cloth, \$4.00.

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates and numerous woodcuts. In one 8vo. vol. of 568 pp. Cloth, \$3.75.

LEISHMAN, WILLIAM, M. D.,*Regius Professor of Midwifery in the University of Glasgow, etc.*

A System of Midwifery, Including the Diseases of Pregnancy and the Puerperal State. Third American edition, revised by the Author, with additions by JOHN S. PARRY, M. D., Obstetrician to the Philadelphia Hospital, etc. In one large and very handsome octavo volume of 740 pages, with 205 illustrations. Cloth, \$4.50; leather, \$5.50; very handsome half Russia, raised bands, \$6.00.

The author is broad in his teachings, and discusses briefly the comparative anatomy of the pelvis and the mobility of the pelvic articulations. The second chapter is devoted especially to the study of the pelvis, while in the third the female organs of generation are introduced. The structure and development of the ovum are admirably described. Then follow chapters upon the various subjects embraced in the study of midwifery. The descriptions throughout the work are plain and pleasing. It is sufficient to state that in this, the last edition of this well-known work, every recent advancement in this field has been brought forward.—*Physician and Surgeon*, Jan. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic. In the

preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted. Complete in all its parts, essentially modern in its teachings, and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

SMITH, J. LEWIS, M. D.,*Clinical Professor of Diseases of Children in the Bellevue Hospital Medical College, N. Y.*

A Complete Practical Treatise on the Diseases of Children. Fifth edition, thoroughly revised and rewritten. In one handsome octavo volume of 836 pages, with illustrations. Cloth, \$4.50; leather, \$5.50; very handsome half Russia, raised bands, \$6.

This is one of the best books on the subject with which we have met and one that has given us satisfaction on every occasion on which we have consulted it, either as to diagnosis or treatment. It is now in its fifth edition and in its present form is a very adequate representation of the subject it treats of as at present understood. The important subject of infant hygiene is fully dealt with in the early portion of the book. The great bulk of the work is appropriately devoted to the diseases of infancy and childhood. We would recommend any one in need of information on the subject to procure the work and form his own opinion on it, which we venture to say will be a favorable one.—*Dublin Journal of Medical Science*, March, 1883.

There is no book published on the subjects of which this one treats that is its equal in value to the physician. While he has said just enough to impart the information desired by general practi-

tioners on such questions as etiology, pathology, prognosis, etc., he has devoted more attention to the diagnosis and treatment of the ailments which he so accurately describes; and such information is exactly what is wanted by the vast majority of "family physicians."—*Va. Med. Monthly*, Feb. 1882.

It is a pleasure to peruse such a work as the one before us, and as reviewers we have but one difficulty—there is but little to find fault with. The author understands what he writes about from a practical acquaintance with the diseases incident to infancy and childhood, and also thoroughly comprehends their pathology and therapeutics. The work is full of original and practical remarks which will be particularly acceptable to the student and young physician; but at the same time we can with great sincerity commend it to the notice of the profession in general.—*Edinb. Med. Jl.*, May, '82.

KEATING, JOHN M., M. D.,*Lecturer on the Diseases of Children at the University of Pennsylvania, etc.*

The Mother's Guide in the Management and Feeding of Infants. In one handsome 12mo. volume of 118 pages. Cloth, \$1.00.

Works like this one will aid the physician immensely, for it saves the time he is constantly giving his patients in instructing them on the subjects here dwelt upon so thoroughly and practically. Dr. Keating has written a practical book, has carefully avoided unnecessary repetition, and successfully instructed the mother in such details of the treatment of her child as devolve upon her. He has studiously omitted giving prescriptions, and instructs the mother when to call upon the doctor, as his duties are totally distinct from hers.—*American Journal of Obstetrics*, October, 1881.

Dr. Keating has kept clear of the common fault of works of this sort, viz., mixing the duties of the mother with those proper to the doctor. There is the ring of common sense in the remarks about the employment of a wet-nurse, about the proper food for a nursing mother, about the tonic effects of a bath, about the perambulator *versus* the nurse's arms, and on many other subjects concerning which the critic might say, "surely this is obvious," but which experience teaches us are exactly the things needed to be insisted upon, with the rich as well as the poor.—*London Lancet*, January 28, 1882.

WEST, CHARLES, M. D.,*Physician to the Hospital for Sick Children, London, etc.*

Lectures on the Diseases of Infancy and Childhood. Fifth American from the sixth revised and enlarged English edition. In one large and handsome octavo volume of 686 pages. Cloth, \$4.50; leather, \$5.50.

By the Same Author.

On Some Disorders of the Nervous System in Childhood. In one small 12mo. volume of 127 pages. Cloth, \$1.00.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American from the second English edition. In one octavo volume of 286 pages. Cloth, \$2.50.

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one octavo volume of 779 pages. Cloth, \$3.25; leather, \$3.25.

TIDY, CHARLES MEYMOTT, M. B., F. C. S.,

Professor of Chemistry and of Forensic Medicine and Public Health at the London Hospital, etc.

Legal Medicine. VOLUME I. Embracing Evidence, The Signs of Death, Identity, The Causes of Death, The Post-mortem, Sex, Monstrosities, Hermaphroditism, Expectation of Life, Presumption of Death and Survivorship, Heat and Cold, Burns, Lightning, Explosives, Starvation. Making a very handsome imperial octavo volume of 664 pages, with 2 beautifully-colored plates. Cloth, \$6.00; leather, \$7.00. *Just ready.*

He whose inclinations or necessities lead him to assume the functions of a medical jurist wants a book encyclopædic in character, in which he may be reasonably sure of finding medico-legal topics discussed with judicial fairness, with sufficient completeness, and with due attention to the most recent advances in medical science. Mr. Tidy's work bids fair to meet this need satisfactorily.

The fact that the very numerous illustrative cases are drawn from many sources, and are not limited, as in Casper's Handbook, to the author's own experience, and the additional fact that they are brought down to a very recent date, give them, for purposes of reference, a very obvious value.—*Boston Medical and Surgical Journal*, Feb. 8, 1883.

TAYLOR, ALFRED S., M. D.,

Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital, London.

A Manual of Medical Jurisprudence. Eighth American from the tenth London edition, thoroughly revised and rewritten. Edited by JOHN J. REESE, M. D., Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania. In one large octavo volume of 937 pages, with 70 illustrations. Cloth, \$5.00; leather, \$6.00; half Russia, raised bands, \$6.50.

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and the eighth comes before us as embodying the latest thoughts and emendations of Dr. Taylor upon the subject to which he devoted his life with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should

only have to seek for laudatory terms.—*American Journal of the Medical Sciences*, Jan. 1881.

This celebrated work has been the standard authority in its department for thirty-seven years, both in England and America, in both the professions which it concerns, and it is improbable that it will be superseded in many years. The work is simply indispensable to every physician, and nearly so to every liberally-educated lawyer, and we heartily commend the present edition to both professions.—*Albany Law Journal*, March 28, 1881.

By the Same Author.

The Principles and Practice of Medical Jurisprudence. Third edition. In two handsome octavo volumes, containing 1416 pages, with 188 illustrations. Cloth, \$10; leather, \$12. *Just ready.*

The revision of the third edition of this standard work has been most happily confided to a gentleman who was during fourteen years the colleague of the author, and who therefore is thoroughly conversant with the methods of thought which have everywhere gained for the book an exalted position as a work of reference. The present edition, though not so large as its predecessor, contains a large amount of new matter which has been accommodated by a careful condensation wherever it was compatible with clearness. The chapters on poisoning have been in some parts entirely rewritten, a change demanded by the recent advances in this department of Forensic Medicine, and many illustrative cases have been added throughout the entire work. In its present form the work is the most complete exposition of Forensic Medicine in the English language.

By the Same Author.

Poisons in Relation to Medical Jurisprudence and Medicine. Third American, from the third and revised English edition. In one large octavo volume of 788 pages. Cloth, \$5.50; leather, \$6.50.

LEA, HENRY C.

Superstition and Force: Essays on The Wager of Law, The Wager of Battle, The Ordeal and Torture. Third revised and enlarged edition. In one handsome royal 12mo. volume of 552 pages. Cloth, \$2.50.

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that

should not be most carefully studied; and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

By the Same Author.

Studies in Church History. The Rise of the Temporal Power—Benefit of Clergy—Excommunication. New edition. In one very handsome royal octavo volume of 605 pages. Cloth, \$2.50. *Just ready.*

The author is pre-eminently a scholar. He takes up every topic allied with the leading theme, and traces it out to the minutest detail with a wealth of knowledge and impartiality of treatment that compel admiration. The amount of information compressed into the book is extraordinary. In no other single volume is the development of the

primitive church traced with so much clearness, and with so definite a perception of complex or conflicting sources. The fifty pages on the growth of the papacy, for instance, are admirable for conciseness and freedom from prejudice.—*Boston Traveller*, May 3, 1883.
